The light-house now began to appear considerably above the rock at low-water; and the tide's work, in moderate weather, extending to five or six hours, or an hour or two after the rock was under water. The shelter-house was now fully occupied as a barrack, smithy, and mortar gallery; and between this fabric and the rising walls of the light-house, a rope ladder of communication was distended.

Upon Sunday, the 20th of August, this year, the entire twenty-second course of the building, consisting of 51 blocks, was laid; after which, for the first time, prayers were read in the shelter-house, the whole workmen being assembled in one apartment, and two of them joining hands to form a desk to support the Bible during the service. On the 25th of this month, the building operations were brought to a conclusion for the season.

At the commencement of the works in spring, 1810, a great stock of prepared materials was in readiness at Arbroath, excellent sand-stone having been procured from Milnfield Quarry, on the Frith of Tay. The stones for the cornice and light-house, from Craigleith, near Edinburgh, were likewise prepared, and in readiness for shipping at Leith. A large gangway or bridge of timber had been prepared during the winter, to render the communication between the shelter-house and light-house more perfect, than by means of the rope ladder; and which was calculated to be of great use for raising the materials upon the building.

The first circumstance attended to, in commencing the operations of this season, was to fix upon the proper situation for the door of the light-house; and the heaviest seas being determined to be from the north-east, the door was laid off towards the south-west. The first cargo of stones was brought to the rock about the middle of May; and from the very complete and systematic arrangement of the works, the building operations were brought to a close during the month of August, without any material obstacle having been experienced. This increased facility in building was ascribed partly to the experience acquired by practice during former seasons, and partly to the admirable adaptation of the balance crane, formerly mentioned, for laying the stones on their places upon the building. The works were, however, occasionally interrupted, by the shipping being dispersed in gales of wind, when they were sometimes driven upwards of forty miles from their station. At such times, the artificers were closely cooped up in their barrack upon the rock, in a state of painful inactivity, and often with prospects very forlorn. It is certainly not a little remarkable, that in the course of their extensive operations, not a single stone was lost, or even so damaged as to be rendered unfit for the building, notwithstanding the numerous changes and shiftings from hand to hand, which each stone underwent before it was finally laid with mortar. In some instances, indeed, blocks of stone were lifted from their beds by the run of the sea; but none were carried entirely away.

In the engravings, we have given an elevation, plan, section, and details of the light-house. The lower courses of stones were trenched and wedged together with oak timber to the height of upwards of forty feet, or throughout the solid part of the building. At the stone staircase, leading from the door to the first floor, the walls are of the medium thickness of about

seven feet; this thickness gradually diminishes upwards, till, under the cornice of the building, it extends only to 18 inches. The stones of the walls of the several apartments are connected at the ends with dove-tail joints, instead of square joggles, as in the solid, and in the staircase. The floors are constructed in a manner which adds much to the bond or union of the fabric. Instead of being arched, which would have given a tendency or pressure outwards, on the walls, the floors are formed of long stones, radiating from the centre of the respective apartments, and at the same time, forming a course of the outward wall of the building; these floor stones are also joggled sidewise, and, upon the whole, form a complete girth at each story. This is very well seen in figures K and H. In this manner, the pressure of the floors upon the walls is rendered perpendicular, while the side joggles resemble the *groove and feather* in carpentry, exemplified in figs. D, E, and F. In the stranger's room, or library, the roof takes an arched form, but the curve is cut only upon the interior ends of the stones of the cornice, the several courses of which it is composed being all laid upon level beds. This is seen in fig. 2.

Towards the latter end of August, the masonry was completed, and the operations of erecting the light-room commenced. The shelter-house, which had hitherto been crowded by more than 30 persons, during the summer, was now more thinly peopled. Towards the end of the month of October, the balance crane, and the bridge of communication were dismantled; the former was no longer necessary, and in place of the latter the rope ladder was again distended; the shelter-house being still occupied as the place of accommodation for the artificers employed in fitting up the light-roof and reflecting apparatus: seen in figs. 2, and K. In the month of December the keepers took possession of the light-house: about the middle of that month, the whole apparatus and stores, having been safely landed and lodged in the house, the light was advertised for exhibition on the 1st of February, 1811. On the afternoon of that day, it was accordingly exhibited; and the floating light was extinguished, as being no longer necessary.

Since the completion of the light-house, the shelter-house has been removed, and also part of the iron railways, leaving only such tracks of them upon the rock, as were thought necessary for landing the stores, and communicating with the light-house. Instead of a rope ladder, the communication between the rock and the entrance door, a height of about 30 feet was also formed by a brazen stair, which answered also for part of a thunder rod, and facilitated the raising of the stair, by a peculiar sort of crane adapted to the purpose. The fortunate position of the entrance door rendering it seldom necessary to shut it in summer, an inner door of brass has been hung, which is found to be a great convenience to the inmates. During storms, when their double doors, double windows, and storm shutters, are closed, the light-keepers mention that they occasionally feel a tremor in the building, from the shocks of the sea, but that all is quiet within, and they hear nothing of the dashing and roaring noise of the sea.

We shall now proceed to describe the details of the work as represented in the various engravings on the plate:—

Fig. (second) A, the shelter-house used as a barrack, consisted of several stories, viz.

Fig. (second) B, is the lower floor, or a gallery in which the smiths and mortar-makers latterly worked, with the position of the bellows, anvil, hearth, lime tubs, and mortar casks.

Fig. (second) C, represents the second floor of the cooking-room, the caboose or hearth, chimney, provision casks, and the life-boat suspended by davits from the principal beams of the shelter-house.

Fig. (first) D, is the ground plan of the fourth floor, in which the workmen resided; the five parallelograms shew the position of the beds, which were also ranged in five heights, excepting at the man-hole or place of entrance, where were only three.

Fig. (first) E, is the third floor, or foreman and engineer's cabins. Here also their assistants resided.

Fig. (first) F, represents one of the principal beams cut across at the clasp-plate, and the great iron stanchions and spear bolts that bound the whole together.

Fig. (first) G, represents part of one of the beams of the shelter-house connected with the great stanchions, with its

bolts, which were fitted on each side of the beam; the elasp-plates and spear bolts that bound the whole, and fixed it to the rock, are plainly marked.

Fig. (first) H, is an enlarged view of two of the bracing chains, with their tightening shackle meeting in a strong ring attached to the massive iron batts sunk into the rock about 20 inches, and wedged with timber.

Fig. 1, is an outside view of the Bell Rock Light-house.

Fig. 2, is an entire section of the Pharos or Light-house, exhibiting its various stories and apartments, as represented in the following diagrams.

The literals A, B, C, D, E, F, G, H, K, are enlarged views of the several parts of the Pharos just now described.

Fig. (first) A, representing the first entire course of the masonry, measures 42 feet in diameter. The dove-tailed method of connecting the solid part of the Pharos here delineated extends to the height of the entrance door.

Fig. (first) B, the twenty-seventh course and first of the staircase, measures 6 feet 4 inches in diameter, within the walls, and 19 feet 8 inches over the walls. This course is elevated 32 feet 8 inches above the rock at the foundation of the first stone.

Fig. (first) C, the thirty-ninth course of the building and first of the provision store-room, is 45 feet 11 inches above the foundation; 11 feet 9 inches diameter within walls; 18 feet over walls; and from the floor to the roof, the height is 8 feet 7 inches.

Fig. (second) D, is a plan of the floor of the light, or oil room store, being the forty-eighth course, which is 55 feet 10 inches above the foundation. This apartment, within walls, measures 11 feet 10 inches; over walls, 16 feet 10 inches; and its height is 8 feet 7 inches.

Fig. (second) E, being the kitchen floor, forms the fifty-seventh course, which is elevated 65 feet 8 inches above the foundation. This room is 11 feet 11 inches in diameter within, over all 16 feet; and its ceiling is 8 feet 9 inches high.

Fig. (second) F, is the bed room floor, or the sixty-sixth course of the building, and is elevated 75 feet 8 inches above the foundation. It measures 11 feet 11 inches diameter, and over all 15½ feet. The walls are 9 feet in height.

Fig. (second) G, the next in order, is the floor of the library or stranger's room, 85 feet 11 inches above the foundation. Its diameter within 12 feet, over walls 15 feet, and the height of the roof at the centre, is 11 feet 1 inch.

Fig. (second) H, the light room and balcony floor, or 86th course of the building, which is elevated 97 feet 9 inches above the foundation, measures 11 feet in diameter within, and 13 feet 6 inches over walls. The stones of the floor of this apartment, as will be observed in the engraving, extend from the centre stone to the circumference of the balcony, varying from 7 feet to 7 feet 6 inches in length. The parapet wall of the light room has its outward face octagonal, but is worked circular within. The light room measures from the floor to the top of the stone work, or sole of the glazed sash frames, 6 feet.

Fig. K, is a plan of the lantern, shewing the position of the trimming path, and reflector frame. The height of the pharos from the foundation to the sill of the sash frame, is 102 feet 6 inches, and from thence to the lining of the cupola, 13 feet 4 inches.

The net cost of the Bell Rock Light House, and ulterior works connected with that establishment, was £61,331. 9s. 2d. There were 2,083,445 tons of granite and sandstone used in the construction; 13 cubic feet of granite, and 14 cubic feet of sandstone, were allowed to the ton; 204 barrels of sand; 377 barrels of lime; 255 barrels of pozzolano; 6585 wedges of oak, in pairs; 4065 oak trenails; 450 sandstone joggles; 21,598 cubic feet of sandstone, and 6932 cubic feet of granite.

PHASEOLUS, *Kidney Bean*, a genus of the diadelphia decandria class of plants, the corolla whereof is papilionaceous, the vexillum is cordated, obtuse, emarginated, and reclined with reflex sides; the alæ are roundish, of the same length with the vexillum, and stand upon long unguis; the carina is narrow, and revolves spirally in a contrary direction to the sun; the fruit is a long, straight, coriaceous, and obtuse pod; the seeds are oblong, compressed, and kidney-shaped. There are 21 species.

PHASES, in Astronomy, denote the various appearances of the moon at different ages, being at one time a crescent, then a semicircle, then gibbous, and lastly full; after which, the same phases return again in the same order. Venus and Mercury have the same phases as the moon, and Mars partakes of them, in some measure, being at times gibbous; the same must also have place in a less degree with the other superior planets. The same term is also applied to denote the appearance of the moon or sun when eclipsed.

PHASIANUS, the *Pheasant*, in Natural History, a genus of birds of the order Gallinæ. Generic character: bill short, strong, and convex; head covered in some degree with carunculated flesh; legs generally with spurs. There are ten species. *P. gallus*, or the wild pheasant, inhabits the forests of India, and has been seen, indeed, by navigators in almost all the Indian and South Sea islands. This is the undoubted origin of all the domestic varieties throughout Europe, of which we shall notice the following:—*P. gallus*, or the dunghill cock. The most interesting animal under this variety is the game cock, which is found in greater perfection of vigour and courage in England than in any other country; and the irascibility and jealousy of which has, in almost all ages, occasioned it to be employed in the sanguinary diversion of cockfighting.

PHENOMENON, is strictly an appearance, but more commonly confined to those only of an extraordinary nature, particularly as relating to the heavens, or heavenly bodies; as comets, meteors, shooting stars, &c. We also speak of the phenomenon of the magnet, of electricity, &c.

PHILOLOGY, a science, or rather assemblage of several sciences, consisting of grammar, rhetoric, poetry, antiquities, history, and criticism.

PHILOSOPHER, a person well versed in philosophy, or one who makes profession of, or applies himself to the study of, those sciences.

PHILOSOPHY, the knowledge or study of nature or morality, founded on reason and experience, the word originally implying a *love of wisdom*. The only part of philosophy, however, which belongs to a work of this kind, is that which is called natural or experimental philosophy, and which may be generally defined that branch of science which derives its data from experiments and observations, on which the whole system is supported, as is that of geometry upon axioms and definitions.

Natural Philosophy, is the science that unfolds those general principles which connect the events of the material world. It assumes as a basis, the constancy and permanence of the actual state of things. The appearances which present themselves to our observations, are called *phenomena*; and the common relations which pervade these phenomena, are termed laws. The business of the natural philosopher is to ascend patiently from effects to causes, till he approaches the fountain of all power and intelligence; and from that eminence again to descend, and trace the lengthened chain of consequences. This double mode of procedure corresponds to the analysis and synthesis of the ancient Greek geometry. The analysis, or investigation of physical facts, is conducted, either by observation, or by experiment. Observation is the close inspection, and attentive examination, of those phenomena which arise in the course of nature. Experiment, as the term implies, consists in a sort of trial or artificial selection and combination of circumstances, for the purpose of searching after remote results. The main object of the philosopher is always to separate the various effects which are blended together in the ordinary concurrence of events. The primary facts being once detected from close observation, or delicate experiment, the synthetical deduction can be safely pursued by the exercise of a sober and cautious logic. But the most important instrument, in forwarding this process of combination, is geometry, to which indeed we are indebted for whatever is most valuable in physical science. The most satisfactory mode of proceeding in the exposition of the phenomena, is to consider bodies as (1) in a state of rest, and (2) in a state of motion. The essential properties which belong to each distinct body, form a branch of science that may be termed *Somatology*, but which has hitherto been styled incorrectly *Corpuscular Philosophy*.

A course of natural philosophy may be properly distributed under twelve distinct heads:—

1. *Somatology*, which includes the exposition of the general properties of bodies, essential to their separate existence.

2. *Statics*, which explains the equilibrium of bodies, resulting from their mutual action, or from combined pressure and divellence.

3. *Phoronomics*, or *Dynamics*, which explores the laws of motion, and traces the flux of changes produced by the application of force.

4. *Physical Astronomy*, which is the extension of dynamics, to develop the great phenomena of the heavens. It explains the figures and motions of the planets, and deduces their various effects.

5. *Mechanics*, in which the principles of dynamics descend to improve the vulgar arts, and to explain the composition and arrangement of the various machines contrived to assist the labour of man.

6. *Hydrostatics*, which consists in the application of the principles of statics to explain the equilibrium of liquids or of fluids in general. It treats also of the construction of works depending on such properties.

7. *Hydrodynamics*, or *Hydraulics*, which consists in applying dynamics to the motion of liquids. It consequently investigates the construction and performance of the various engines employed to raise water, or which are driven by the impulsion of that fluid.

8. *Pneumatics*, includes the application of statics and dynamics to air and other gaseous fluids. It explains the constitution, the operations, and general phenomena, of our atmosphere.

9. *Photonomics*, which treats of the properties and operations of light.

10. *Pyronomics*, which explores the properties and operations of heat.

11. *Magnetism*, which investigates the properties of the loadstone, and their application to the suspended needle.

12. *Electricity*, which explains all the brilliant phenomena derived from those first produced by the rubbing of amber.

Such appears to be the systematic arrangement of those subdivisions; but it will admit of being conveniently modified, according to the taste or judgment of philosophers.

PHLEGM, or **WATER**, in the animal economy, is considered an elementary body, the characters of which are fluidity, insipidity, and volatility.

PHLEUM Nodosum. (*Bulbous Cat's-Tail-Grass*.) This grows very frequently in dry thin soils, where it maintains itself against the parching sun by its bulbous roots, which lie dormant for a considerable time, but grow again very readily when the wet weather sets in,—a curious circumstance, which gives us an ample proof of the wise contrivance of the great Author of nature, to fertilize all kinds of soil for the benefit of his creatures here below. There is another instance of this in the *Poa bulbosa*. Bulbous meadow-grass, which grows on the Steine at Brighton, and which, after being kept in papers two years out of ground, has vegetated afterwards.

PHLOAS, a genus of vermes testacea. The inhabitants of this genus perforate clay, spongy stones and wood, while in the younger state, and they increase in size, enlarge their habitation within, and thus become imprisoned. They contain a phosphorus liquor, of great brilliancy in the dark, and which illuminates whatever it touches. There are 12 species.

PHOCA, the *Seal*, in Natural History, a genus of mammalia of the order feræ. There are nineteen species, of which we shall notice the following:—The common seal, or sea-calf, found on the sea coasts of cold regions, both to the north and south, often in extreme abundance, and generally about five feet in length, closely covered with short hair. They swim with great vigour and rapidity, and subsist on various kinds of fish, which they are often observed to pursue within a short distance from the shore. They possess no inconsiderable sagacity, and may without much difficulty, if taken young, be familiarized to their keepers, and instructed in various gesticulations. They are supposed to attain great longevity. The female is particularly attentive to her young, and scarcely ever produces more than two at a birth, which, after being suckled a fortnight on the shore, where they are always born, are conducted to the water, and taught by their dam the means of defence and subsistence; and when they are fatigued by their excursions, are relieved

by being taken on her back. They distinguish her voice, and attend at her call. The flesh of seals is sometimes eaten, but they are almost always destroyed for their oil and skins. The latter are manufactured into very valuable leather, and the former are serviceable in a vast variety of manufactures. The ursine seal grows to the length of eight feet, and to the weight of a hundred pounds. These are found in vast abundance in the islands between America and Kamtschatka, from June till September, when they return to the Asiatic or American shores. They are extremely strong, surviving wounds and lacerations which almost instantly destroy life in other animals, for days, and even weeks. They may be observed not merely by hundreds, but by thousands, on the shore; each male surrounded by his females, from eight to fifty, and his offspring amounting frequently to more than that number. Each family is preserved separate from every other. The ursine seals are extremely fat and indolent, and remain with little exercise, or even motion, for months together upon the shore. This harmless seal has been frequently mistaken for the fabled mermaid.

PHENICOPTEROS, the *Flamingo*, in Natural History, a genus of birds of the order grallæ. The common flamingo, the only species noticed by Latham, is nearly of the size of a goose, and upwards of four feet long. When mature in plumage, these birds are all over of the most deep and beautiful scarlet; but this maturity they never acquire till their third year. They are found in France, Spain, and Italy, in Syria, and in Persia, but more frequently than any where else, on the coast of Africa, downwards to the Cape. They build their nest of mud, in the shape of a hillock, and in a cavity on the top of it the female deposits two white eggs, on which she sits, having her legs stretched out, one each side of the hillock.

PHENIX, the great palm or date tree, a genus of plants of the order palmæ. There is only one species, viz. the dactylifera, or common date tree, a native of Africa and the eastern countries, where it grows to 50, 60, and 100 feet high.

PHENIX, in Astronomy. Our astronomers have probably given this constellation the name of Phoenix, after the example of the Arabians, who were acquainted with it under the appellation of the Griffin, or Eagle, from the most remote antiquity. These people adored an idol under the form of an eagle, and according to Hyde, (*Hist. Vet. Pers.*) this eagle was one of the celestial signs. The brilliant star called *Achernar*, beside this asterism, is distinctly visible during the summer months in Arabia, whence the Phoenix was fabled to come. Erasmus says the Phoenix was the symbol of the year, or of the annual revolution; and to the Egyptians this constellation rose, as it were, from Arabia, shortly before the commencement of their sacred year.

PHONICS, the same as **ACOUSTICS**.

PHOSPHATS, salts formed by the phosphoric acid, with the alkalies, earths, and metallic oxides. The phosphats at present known amount to twelve; two of which are triple salts.

PHOSPHITES, salts formed with the phosphorous acid united to the earths, alkalies, and metallic oxides.

PHOSPHORIC ACID. The base of this acid, or the acid itself, abounds in the mineral, vegetable, and animal kingdoms. In the mineral kingdom it is found in combination with lead, in the green lead ore; with iron, in the bog ores which afford cold-short iron; and more especially with calcareous earth in several kinds of stone. Whole mountains in the province of Estremadura, in Spain, are composed of this combination of phosphoric acid and lime. In the animal kingdom it is found in almost every part of the bodies of animals which are not considerably volatile. There is not, in all probability, any part of these organized beings which is free from it. It has been obtained from blood, flesh, both of land and water animals; from cheese; and it exists in large quantities in bones, combined in calcareous earth. Urine contains it not only in a disengaged state, but also combined with ammonia.

PHOSPHOROUS ACID is prepared by exposing phosphorus during some weeks to the ordinary temperature of the atmosphere. Even in winter the phosphorus undergoes a slow combustion, and is gradually changed into a liquid acid. For this purpose it is usual to put small pieces of phosphorus on the inclined side of a glass funnel, through which the liquor which is formed drops into the bottle placed to receive it. From

an ounce of phosphorus about three ounces of acid liquid may be thus prepared.

PHOSPHORUS, a substance which shines by its own light. The discovery of this singular substance was accidentally made in 1677, by an alchemist of Hamburgh, named Brandt, when he was engaged in searching for the philosopher's stone. Kunkel, another chemist, who had seen the new product, associated himself with one of his friends, named Kraft, to purchase the secret of its preparation; but the latter deceiving his friend, made the purchase for himself, and refused to communicate it. Kunkel, who at this time knew nothing further of its preparation, than that it was obtained by certain processes from urine, undertook the task, and succeeded. It is on this account that the substance long went under the name of Kunkel's phosphorus. Mr. Boyle is also considered as one of the discoverers of phosphorus. He communicated the secret of the process for preparing it, to the Royal Society of London, in 1680. It is asserted indeed by Kraft, that he discovered the secret to Mr. Boyle, having, in the year 1678, carried a small piece of it to London, to shew it to the royal family; but there is little probability that such a man as Mr. Boyle would claim the discovery as his own, and communicate it to the Royal Society, if this had been the case. Mr. Boyle communicated the process to Godfrey Hankwitz, an apothecary of London, who for many years supplied Europe with phosphorus, and hence it went under the name of English phosphorus. In the year 1774, the Swedish chemists, Gahn and Scheele, made the important discovery, that phosphorus is contained in the bones of animals, and they improved the processes for procuring it. The most convenient process for obtaining phosphorus, seems to be that recommended by Fourcroy and Vauquelin, which we shall transcribe. Take a quantity of burnt bones, and reduce them to powder. Put 100 parts of this powder into a porcelain or stone-ware bason, and dilute it with four times its weight of water. Forty parts of sulphuric acid are then to be added in small portions, taking care to stir the mixture after the addition of every portion. A violent effervescence takes place, and a great quantity of air is disengaged. Let the mixture remain for twenty-four hours, stirring it occasionally to expose every part of the powder to the action of the acid. The burnt bones consists of the phosphoric acid and lime, but the sulphuric acid has a greater affinity for the lime than the phosphoric acid. The action of the sulphuric acid uniting with the lime, and the separation of the phosphoric acid, occasion the effervescence. The sulphuric acid and the lime combine together, being insoluble, and fall to the bottom. Pour the whole mixture on a cloth filter, so that the liquid part, which is to be received in a porcelain vessel, may pass through. A white powder, which is the insoluble sulphate of lime, remains on the filter. After this has been repeatedly washed with water, it may be thrown away; but the water is to be added to that part of the liquid which passed through the filter. Take a solution of sugar of lead in water, and pour it gradually into the liquid in the porcelain bason. A white powder falls to the bottom, and the sugar of lead must be added so long as any precipitation takes place. The whole is again to be poured upon a filter, and the white powder which remains, is to be well washed and dried. The dried powder is then to be mixed with one-sixth of its weight of charcoal powder. Put this mixture into an earthenware retort, and place it in a sand bath, with the beak plunged into a vessel of water. Apply heat, and let it be gradually increased till the retort becomes red-hot. As the heat increases, air-bubbles rush in abundance through the beak of the retort, some of which are inflamed when they come in contact with the air at the surface of the water. A substance at last drops out similar to melted wax, which congeals under the water. This is phosphorus. To have it quite pure, melt it in warm water, and strain it several times through a piece of shamoy leather, under the surface of the water. To mould it into sticks, take a glass funnel with a long tube, which must be stopped with a cork. Fill it with water, and put the phosphorus into it. Immerse the funnel in boiling water, and when the phosphorus is melted, and flows into the tube of the funnel, then plunge it into cold water, and when the phosphorus has become solid remove the cork, and push the phosphorus from the mould with a piece of wood. Thus prepared, it must be preserved in

close vessels containing pure water. When phosphorus is perfectly pure it is semi-transparent, and has the consistence of wax. It is so soft that it may be cut with a knife. Its specific gravity is from 1.77 to 2.03. It has an acid and disagreeable taste, and a peculiar smell, somewhat resembling garlic. When a stick of phosphorus is broken, it exhibits some appearance of crystallization. The crystals are needle-shaped, or long octahedrons; but to obtain them in their most perfect state, the surface of the phosphorus, just when it becomes solid, should be pierced, that the internal liquid phosphorus may flow out, and leave a cavity for their formation. When the phosphorus is exposed to the light, it becomes of a reddish colour, which appears to be an incipient combustion. It is, therefore, necessary to preserve it in a dark place. At the temperature of 90° it becomes liquid, and if air be entirely excluded, it evaporates at 219°, and boils at 554°. At the temperature of 43° or 44° it gives out a white smoke, and is luminous in the dark: this is a slow combustion of the phosphorus, which becomes more rapid as the temperature is raised. When phosphorus is heated to the temperature of 148° it takes fire, burns with a bright flame, and sends out a great quantity of white smoke. Phosphorus enters into combination with oxygen, azote, hydrogen, and carbon. Phosphorus is soluble in oils, and when thus dissolved, forms what has been called liquid phosphorus, which may be rubbed on the face and hands without injury. It dissolves too in ether, and a very beautiful experiment consists in pouring this phosphoric ether in small portions, and in a dark place, on the surface of hot water. The phosphoric matches consists of phosphorus extremely dry, minutely divided, and perhaps a little oxygenized. The simplest mode of making them, is to put a little phosphorus, dried by blotting paper, into a small phial; heat the phial, and when the phosphorus is melted turn it round, so that the phosphorus may adhere to the sides. Cork the phial closely, and it is prepared. On putting a common sulphur match into a bottle, and stirring it about, the phosphorus will adhere to the match, and will take fire when brought out into the air.

PHOSPHURETS, substances formed by an union of the alkalis, earths, and metallic oxides, with phosphorus. Thus we have phosphuret of lime, &c.

PHOTOMETER, an instrument intended to indicate the different quantities of light, as in a cloudy or bright day, or between bodies illuminated in different degrees. In Leslie's photometer, the essential part is a glass tube like a reversed syphon, whose two branches should be equal in height, and terminated by balls of equal diameter; one of the balls is of black enamel, and the other of common glass, into which is put some liquid. The motion of the liquor, which is sulphuric acid tinged red with carmine, is measured by means of a graduation, the zero is situated towards the top of the branch that is terminated by the enamelled ball. The use of this instrument is founded upon the principle, that when the light is absorbed by a body, it produces a heat proportional to the quantity of absorption. When the instrument is exposed to the solar rays, those rays that are absorbed by the dark colour heat the interior air, which causes the liquor to descend at first with rapidity in the corresponding branch. But as a part of the heat which had introduced itself by means of the absorption is dissipated by the radiation, and as the difference between the quantity of heat lost and that of the heat acquired goes on diminishing, there will be a point where, these two quantities having become equal, the instrument will be stationary, and the intensity of the incident light is then estimated by the number of degrees which the liquor has run over. The author of this ingenious instrument has pointed out its advantages in determining the progressive augmentation undergone by the intensity of the light, and the gradation in a contrary sense which succeeds to that progress, both from the beginning of the day to its end, and from the winter solstice to the end of the succeeding autumn. With the help of such an instrument, one might also compare the action of the rays of light in different countries, of which some dart with sufficient constancy from a fine and serene sky, while others seem to be covered with a veil which dims and obscures their lustre.

PHYGETHLON, in Surgery, a broad but not much elevated tumour, of the same nature with the bubo.

PHYLACTERY, in Antiquity, a charm or amulet, which being worn, was supposed to preserve people from certain evils, diseases, and dangers.

PHYSETER, *Cachalot*, a genus of fishes of the order cete. *Physeter macrocephalus*, blunt-headed cachalot. This whale, which is one of the largest species, is scarcely inferior in size to the great mysticete, often measuring sixty feet or more in length. The head is of an enormous size, constituting more than a third of the whole animal; the mouth wide, the upper lip rounded, thick or high, and much broader than the lower; which is of a somewhat sharpish form, fitting in a manner into a longitudinal bed or groove in the upper. The teeth, at least the visible ones, are situated only in the lower jaw, and when the mouth is closed, are received into so many corresponding holes or cavities in the upper; they are pretty numerous, rather blunt, and of a somewhat conic form, with a very slight bend or inclination inwards. The front of the head is very abrupt, descending perpendicularly downwards; and on its top, which has been improperly termed the neck by some authors, is an elevation or angular prominence containing the spiracle, which appears externally simple, but is double within. The head is distinguished or separated from the body by a transverse furrow or wrinkle. The eyes are small and black; and the ears or auditory passages extremely small. About the middle of the back is a kind of spurious fin, or dorsal tubercle, of a callosous nature, not moveable, or somewhat abrupt or cut off behind. The tongue is of the shape of the lower jaw, clay-coloured externally, and of a dull red within. The throat is but small in proportion to the animal. The body is cylindrical beyond the pectoral fins, growing narrower towards the tail. The colour of the whole animal is black, but when advanced in age grows whitish beneath. It swims swiftly, and is said to be a violent enemy to the squalus carcharias, or white shark, which is sometimes driven ashore in its endeavours to escape, and, according to Fabricius, will not venture to approach its enemy, even when dead, though fond of preying on other dead whales. It is in a vast cavity within the upper part of the head of this whale, that the substance called spermaceti is found, which, while fresh and in its natural receptacle, is nearly fluid; but when exposed to the air, concretes into opaque masses: this substance being so universally known, it becomes unnecessary to describe it farther. A more curious and valuable production, the origin of which has long eluded the investigation of naturalists, is obtained from this animal, viz. the celebrated perfume called ambergris, which is found in large masses in the intestines, being in reality no other than the faeces.

PHYSICAL, any thing relating to physics.

PHYSICIANS. No person within London, nor within seven miles of the same, shall exercise as a physician or surgeon, except he is examined and approved by the bishop of London, or by the dean of St. Paul's, calling to them four doctors of physic, and for surgery, other expert persons in that faculty, of them that have been approved, upon the pain of forfeiture for every month £5, one half to the king and the other half to any that will sue. One that has taken his degree of doctor of physic in either of the universities, may not practise in London, and within seven miles of the same, without license from the college of physicians.

PHYSICO MATHEMATICS, is the same as mixed mathematics, being those branches of this science which investigates the laws and actions of bodies, and their combinations, by means of certain data drawn from observation and experiment.

PHYSICS, is a term denoting the same as experimental or natural philosophy; being the doctrine of natural bodies, their phenomena, causes, and effects, with their various affections, motions, and operations.

Experimental Physics, is that which inquires into the nature and reason of things by experiments, as in hydrostatics, pneumatics, optics, chemistry, &c.

Mechanical Physics, explains the appearances of nature from the matter, motion, structure, and figures of bodies, and their several parts, according to the established laws of nature.

PHYSIOGNOMY, is the peculiar combination of features, which designates the feelings and dispositions of the mind. That every individual of the human race possesses a set of

distinctive marks, in the form of the head and the outlines of the countenance, is visible to the most inattentive observer: and it is well known, that those marks insensibly lead us to form conclusions as to the nature and inclinations of persons to whom we are introduced for the first time, which may sometimes be correct, but are frequently erroneous. Admitting this fact, as to mankind in general, it will be proper to observe, that however the study of physiognomy may be commended and recommended, it should be exercised with great discretion and judgment, or very fatal, or, at least very disagreeable, consequences may be the result; for it must be remembered, that numerous causes exist to derange and decompose the human frame during infancy, and even before the birth, which may impress a character or expression on the features, descriptive of evil passions that never existed in the mind of the unfortunate person so situated; for instance, it would be inhuman to judge of the soul of one who has had the vertebrae of his back doubled, from the expression of his face, which is uniformly that of peevishness and confirmed ill-nature; nor would it be just to think a man capable of every kind of wickedness, whose head and face bear the marks of malice, through a deformity existing perhaps before his birth. Were the bones incompressible from the instant they are formed, and the muscles incapable of being moulded to their shape, in short, did mankind receive a decided and unalterable outline from the Creator, we should then make correct conclusions from the beauty or irregularity of the face. The aid of Lavater is not necessary to inform us that there exists a national physiognomy, by which a stranger in any given country may be known by those who are possessed of previous observation, to be a Spaniard, a German, or a Frenchman, and which impels even the very vulgar to exclaim, "He is a foreigner," though they cannot appropriate him to his country. After all, it will be admitted that this science, if such it can fairly be denominated, must be precarious, and, in some respects, delusive. It cannot, however, be doubted, that there is an apparent correspondence between the face and the mind: the features and lineaments of the one are directed by the motions and affections of the other; there is, perhaps, even a peculiar arrangement of the members of the face, and a peculiar disposition of the countenance to each particular affection of the mind.

PHYSIOLOGY, is the science which treats of the powers that actuate the component parts of living animal bodies, and of the functions which those bodies execute. The life of a body is better known by observation than can be described by words. If it be possible to give a sort of definition of it, the following is as true as it will admit of: that life tends by an universal sympathy, or assimilating action, to produce another body similar to itself. This sympathy seems to exist between the circulating and the nervous systems; as for instance, in order that sensibility may be acute (or secretion performed) a very extensive circulation, and an equally diffuse distribution of nerves, is necessary. We may conveniently consider the nervous system as consisting of the brain, spinal cord, and nerves; and the vascular system as consisting of arteries, veins, absorbents and exhalants, universal; while the others, as the respiratory, nutritive, generative, and those of waste, may be called partial systems. The nervous system especially tends, from its supplying us with sensibility and heat, to oppose the processes consequent to mere matter. The brain is the organ of the mind. The cerebral lobes are the seat of sensation and volition. The cerebellum regulates the actions of running, walking, standing, flying, &c. The spinal cord, with the medulla oblongata, corpora quadrigemina, and nerves, are the seat of those impressions which give rise to muscular contractions; and the spinal cord combines or generalizes the contractions, so as to produce motion of the joints. The spinal cord seems to be formed previous to the development of the brain, and is so necessary to life that few animals want it, and is perfect in proportion as their organization is perfect. The human species is endowed with three sorts of nerves, viz. 1. Those of the different external senses. 2. Those requisite for motion. 3. Those necessary to the supply and waste of the machine. The contraction of both sides of the heart takes place at the same time. Arteries are conical tubes, whose base

originates from the heart; they have a tonic power depending on their degree of life, the vessels are constantly full of blood, so that the quantity sent out from the ventricle merely acts as a jet upon the mass already in the arteries, and gives to the containing vessels a sort of motion. The blood in the veins is urged on partly by the power behind, and also by a species of suction exerted from the right side of the heart. The general circulation may be thus described: all the blood, except that of the lungs, is brought to the right auricle, and compressed into the right ventricle to be circulated through the lungs, whence it is returned by the pulmonary veins to the left auricle, thence sent into the left ventricle, to be distributed through the whole body, except the lungs. The blood, in passing through the lungs loses that dark colour acquired from its tardy transmission by the veins, the change is most probably decarbonization, and is necessary to the healthy action of the heart. Some peculiarities may be noticed relating to the circulation; the connexion of the circulation in the genital organs and mamma. That of the liver which is entirely venous, and consisting of the blood which had been distributed to the organs of digestion, collected into a large vein, (*vena portæ*), which again ramifies itself like an artery through the substance of the liver. Again the circulation through the brain is by arteries terminating in sinuses, and upon the principle of the syphon. The absorbents, as constituting part of the vascular system, may be arranged into two classes; those which absorb a fluid necessary to the nutrition of the body, and those which admit of grosser substances. The first are those which arise from the stomach and intestinal canal, and terminate in the thoracic duct to enter the venous system by the subclavians. The others are spread over the whole body, and enter the veins in their neighbourhood: each of those sets has a sort of elective power.

Of the partial Systems:—The external senses, sight, hearing, taste, smell, and touch, depend upon a proportional increase of the universal systems. Respiration is essential to the maintenance of the circulation, the lungs are full of cells into which there is an exhalation from the arteries ramified on them, it is here where the blood becomes decarbonated, or, as some would have it, oxygenated. Absorption is exceedingly quick in them. The action of the lungs may be compared to the action of two bladders within a bellows, and fitted by means of a common communication to the tube of the bellows, no air being admitted by the tube or usual hole into the cavity of the bellows external to the bladder. Another important use of the lungs is by its forcible emission of air through the glottis, producing voice, which, modified by the tongue, palate, teeth, and lips, furnishes us with the power of articulation. We may now consider the circle of organs engaged in nutrition or supply and waste. There is a sympathy extending along the whole range of these organs, *viz.* the mouth, gullet, stomach, and spleen, intestines, and liver, and pancreas; so that if any thing should be conveyed into the stomach, even without the action of the mouth, a secretion of saliva would take place, &c. Alimentation commences with the mastication of the food, during which action it is mixed with saliva, it is then swallowed, mixed with the gastric juice in the stomach, converted into a mass called chyme, thence passes into the bowels; coming in contact with the biliary and pancreatic secretions, it is separated into two substances, one named chyle, which is to be absorbed for the nutrition of the frame, the other to be evacuated. Hunger arises from the action of the gastric juice on the coats of the stomach.—The foetus is not part of the body of the mother, but derives its own nourishment as a distinct animal by its own mechanism. Its mechanism serves only for its nourishment, being an imperfect animal, and not enjoying any of the external senses. The circulation of the blood in the foetus is different. The blood from the umbilical vein partly passes through the liver, partly by the ductus venosus, into the vena cava, thence to the right auricle, the right auricle throws it partly into the right ventricle, but the greater part through the foramen ovale into the left auricle. The portion sent to the right ventricle is transmitted through the pulmonary artery to the lungs in part, and also by the *canalis arteriosus* into the aorta. The blood which the pulmonary veins bring into the left auricle passes with that through the foramen ovale into the left ventricle, to be transmitted through

the aorta to the whole system. The urinary system serves to throw off the urea from the circulation, consequently a mere organ of waste.

PHYTOLOGY, a discourse concerning the kinds and virtues of plants.

PHYTOTAMA, a genus of birds of the order *passeres*. There is only a single species, *viz.* *P. rara*, that inhabits Chili.

PIASTER, a Spanish coin of the value of 4s. 6d. sterling.

PIAZZA, in Architecture, is a portico, or covered walk supported by arches; and all walks with porticos around them, are piazzas, as the fine walks around the Royal Exchange, London, one of the most classical and yet national monuments to be found in Europe.

PICÆ, the second order of birds, according to the Linnæan system. The male feeds the female while she is sitting. They live in pairs. Of this order there are twenty-six genera.

PICARD, JOHN, a celebrated French mathematician and astronomer of the 17th century, was the first who applied the telescope to astronomical instruments, and commenced the publication of the "*Connaissance des Temps*," which he calculated from 1679 to 1683. He also first measured the length of a degree of the meridian in France, and gave a map of that country. The time of his birth is not known, but he died in 1682 or 1683. Picard was author of several works on Levelling, Dialling, Dioptrics, Discharge and Mensuration of Fluids, Astronomy, &c. the whole of which are given in the 6th and 7th volumes of the *Memoirs of the Academy of Sciences*.

PICKETS, in Fortification, sharp stakes about three feet long, sometimes shod with iron, used in laying out ground. But when used for pinning the fascines of a battery, they are from three to five feet long. In the Artillery, pickets five feet long, are used to pin the park lines; in the camp, they are used about eight inches long, to fix the tent cords; or five feet long in the cavalry camp, to fasten the horses.

PICRANIA AMARA, a bitter wood of Jamaica, belonging to the pentandria class of plants. The tree is tall, its timber beautiful, but every part of it is intensely bitter; and in cabinet work it is invaluable, as no insect will live near it. How excellent then for beds! This tree has a great affinity to the quassia amara of Linnæus, in lieu of which, it is used as an antiseptic in putrid fevers.

PICQUET, a celebrated game at cards played between two persons, with only thirty-two cards; all the twos, threes, fours, fives, and sixes, being set aside.

PICUS, the *Wood-pecker*, in Natural History, a genus of birds of the order *Picæ*. These birds live principally upon insects, to obtain which they climb trees, and are perpetually in search of those crevices in which their food is lodged: there are fifty species. The greatest black wood-pecker, abounds in Germany, and builds in ash and poplar trees, which they are said to excavate speedily, so as to expose them to be blown down by winds which would not otherwise have affected them; under the hole made by these birds may be often found several pecks of dust and pieces of wood. They are of the size of a jackdaw. The green wood-pecker, is the largest species in Great Britain, and is thirteen inches long. These birds are more frequently seen on the ground than the other species, particularly where ant-hills abound, the population of which they almost extirpate by their incessant efforts. The witwall, is nine inches long, and strikes with far greater comparative force against the trees than any of the tribe.

PIEPOUDRE, *Court of*, the lowest, and at the same time the most expeditious, court of justice known to the law of England. It is called *piepoudre* (*curia pedis pulverisati*) from the dusty feet of the suitors. But the etymology given us by a learned modern writer is much more ingenious and satisfactory; it being derived, according to him, from *piepoudre*, "a pedlar," in old French, and therefore, signifying the court of such petty chapmen as resort to fairs or markets. It is a court of record, incident to every fair and market; of which the steward of him who owns or holds the toll of the market is the judge. It was instituted to administer justice for all commercial injuries done in that very fair or market, and not in any preceding one; so that the injury must be done, complained of, heard, and determined, within the compass of one and the same day, unless the fair continues longer.

Views of Suspension Bridges.

Loth Suspension Pier

Suspension Pier at Brighton.

Iron Hanging Bridge over the Menai at Bangor Ferry

Elevation of the Suspension Bridge at Kils, on the Fawc

Suspension Bridge constructed in

England for the Isle of Wight

PIER, a strong mound or fence projecting into the sea, to break off the violence of the waves from the entrance of a harbour.

PIERS, in the theory of Bridges, are the walls built to support the arches, and from which they spring as bases.

Piers and Suspension Bridges. (See Plate.)—In nothing perhaps do the French shew their enmity of the British, more than in depreciating our inventions, and in appropriating to themselves, or assigning to others, plans, discoveries, inventions, and improvements, exclusively British. We are led to this introductory remark by an assertion of Dupin, in his Treatise on the Commercial Power of Great Britain, in which he says, that from North America the noble application of iron to chain bridges was soon transferred to Europe, vol. i. p. 370. Again the French baron tells us, p. 374, "The Americans commenced their constructions about the end of the last century," i. e. about thirty years ago, reckoning from 1826, the period when we published letter P of our Dictionary.

Now it is in print, in opposition to Dupin's assertion, that for a long time the Europeans have had an idea of suspension bridges, as may be seen in the bridges described in the work that Faustus Varientius published in 1625; and "80 years ago," (says Dupin very unguardedly for his admiration of the Americans) "the English threw over the Tees at Winch, near Durham, a bridge of iron wire, which served for foot passengers. The Chinese and Peruvians seem to have been the first nations that used suspension bridges; but those of the latter kept the catenarian bend, and the roads they afforded were very inconvenient in their passage.

To Capt. Brown, of the British navy, we are indebted for the idea and execution of suspension and chain piers, of considerable length, in ports and on shores, where ships are unable to approach the beach for a great distance, even at high water. For the embarkation of troops, cavalry horses, baggage, and munitions of war, these suspension piers are very useful. In 1821, Capt. Brown exhibited the first model of these new constructions at Leith. In order to reach, from the shore, the place in the Forth where ships could keep afloat without danger at high or low water, and in very bad weather, it was necessary to advance 233 yards into the sea, reckoning the distance from the high-water mark on shore. To fill up this long space, three arches of suspension chains were formed, each having 249 feet in span; thus the pier is held by four supports only,—one on shore, and three upon piles in the middle of the sea. To describe this work systematically, we will mention, in succession, the piers, the abutments, the suspension chains, and the flooring or road way.

Piers and Abutments.—The principal pier is that which is at the head of the chain pier; it is formed by six rows of piles, having the same direction with the suspension chains; cross timbers consolidate the part above water, the summit of which leaves a flooring or platform of wood. This platform has a hatchway leading to a flight of stairs, descending as low as the level of low water. A plank thrown across, from the last step to the steam-boats, or other vessels, near the landing pier, enables people either to land or to embark. The two intermediate piers, between the shore and the landing place, are formed with piles, so planted as to represent a lozenge; they are covered with a platform, upon which rest the iron benches which bears the suspension chains. To serve as a common support to these chains and their wards, a stone pillar has been built upon the shore, having twenty feet in height upon a square base, six feet on each side; from the top of this pillar or support, the chains, or land-wards, with an inclination of about forty-five degrees, reach the ground, in which they penetrate to a depth of about ten feet, where they are fixed by means of cast-iron ballast plates, in a manner similar to those used by Capt. Brown in the suspension bridge thrown by him across the Tweed. On the side of the landing platform, each of the chains has likewise an inclination of forty-five degrees, and is attached to one of the piles supporting it. Shores, placed obliquely, serve the purpose of resisting the great strains experienced by the chains. The benches used to support the chains, whether seen longitudinally or transversely, are made of iron, open, but combining, nevertheless, lightness with solidity. At the summit they are attached to two oblique

suspending rods, supporting both the landing pier and the flooring.

Suspension Chains, &c.—The suspension chains, as to their form, and the joining together of the parts composing them, resemble those used in the construction of the Union Bridge upon the Tweed; they differ in one point only—the links, which are close to the points of support, having to bear a greater weight, are made thicker than those placed in the middle of the chains. The suspending rods are round, except the lower end, where they fork, in order to receive the flat iron, or lath, which runs along the whole length of the chain pier, and upon which the end of the beams supporting the flooring are resting; the planks forming this flooring are two inches thick. On each side of the pier is a cornice, which covers over the ends of the beams; the parapet is made of iron, four feet high, and firmly joined with the suspending rods.

In order to try the power of this chain pier, Capt. Brown, as soon as it was terminated, loaded it with the immense weight of 210 tons, which he suffered to remain for a great length of time, notwithstanding the casual burden occasioned by passengers, and the shaking produced by their movement. No part of the erection has been observed to suffer from the movements, or by the great strains produced on the chains by so great a burden. Such a fact affords the most satisfactory proof as to the solidity of this system of chain landing piers.

At Brighton, a handsome chain pier is now erected also, but on a scale much more extensive than the Leith pier; it being composed of three inverted arches, having each 230 feet of span; its width is about 12 or 14 feet.

PIG OF BALLAST, a large mass of cast iron or lead, used for ballast.

PIGEONS. Every person who shall shoot at, kill, or destroy a pigeon, may be committed to the common jail for three months, by two justices of the peace, or pay 20s. to the poor. 1 Jac. 1. c. 27.

PIKE, an offensive weapon, consisting of a shaft of wood, twelve or fourteen feet long, headed with a flat-pointed steel, called the spear.

PIKE, or *Jack*, a fish; see *Esox*, p. 276.

PILASTER. See *ARCHITECTURE*.

PILE, in Artillery, denotes a collection or heap of balls or shells, piled up in a pyramidal form, the base being some regular figure, as an equilateral triangle, square, or rectangle, and the whole pile a series of such figures, the side of each successive row diminishing by one from the bottom upwards. Therefore the whole number of balls is equal to the sum of a series of triangular numbers, squares, or rectangles, according to the figure of the pile, by experiment. The algebraic formulae are difficult to remember upon an emergency; and therefore the following general rule, for this purpose, which is not commonly known, is deserving the notice of artillery officers.

Rule.—In every pile there may be found three parallel lines, the sum of which multiplied by the number of balls in the triangular face of the pile, and divided by 3, is the number of balls. In the rectangular pile, the three parallel lines are the two bottom rows in length, and the upper ridge of the pile; and the face the triangular end. In the square pile, any two opposite sides of the square base, and the upper ball, are three parallel lines. And in the triangle pile, one side of the bottom row, the opposite extreme ball, and the upper ball, are the three parallel sides; the face in both these cases being any of the equal slant sides of the pile.

PILE, in Coinage, denotes a kind of puncheon, which in the old way of coining with the hammer, contained the arms, or other figure and inscription, to be struck on the coin.

PILES, in Building, are large stakes or beams sharpened at the end, and shod with iron, to be driven into the ground for a foundation to build upon in marshy places.

Pile Engine, is an engine used for driving piles.

Vaulou's Pile Engine. (See Plate.)—The horses which work this engine are yoked at S S, and by moving the wheel B and drum C, which are locked together, raise the follower G H, (carrying the ram Q by the handle R), by means of the rope H H, which coils round the drum. When the follower G reaches the top of the frame, the upper legs of the tongs H are closed by pressing against the adjacent beams: and their lower legs are

opened, so that they drop the ram Q, which falls and strikes the pile. When G is at the top of the frame, the crooked handle 6, of the follower G, presses against the cords α, α , which raise the end of the lever L (see fig. 2.) round m as a centre, and by depressing the extremity N, and consequently the bar S, S, unlock the drum C and the wheel B, so that the follower G falls by its weight and seizes the ram R. As soon as the follower drops, the horses would tumble down, having no resistance to overcome, were not this prevented by the fly O, which is moved by the wheel B and trundle X, and opposes a sufficient resistance to the horses till the follower again seizes the ram. When the follower falls, the weight L (fig. 2.) pushes up the bolt Y into the drum C, and locks the wheel and the drum; and the same operation is afterwards repeated.

Bunce's Pile Engine. See Plate.—A side view of this engine is shown in fig. 3, 4. It consists of two endless ropes or chains A, connected by cross pieces of iron B, B, &c. (fig. 4.) which pass round the wheel C, the cross pieces falling into corresponding cross grooves, cut in the periphery of the wheel. When the man at S, therefore, drives the wheel m by means of the pinion p , he moves also the wheel C fixed on the axis of m , and makes the double ropes revolve upon the wheels, C, D. The wheel D is fixed at the end of a lever D H K, whose centre of motion is H, a fixed point in the beam F T. Now when the ram L (fig. 3, 5.) is fixed to one of the cross pieces B by the hook M, the weight of the ram acting by the rope, moves the lever D K round H, and brings the wheel D to G, so that by turning the winch, the ram L (fig. 3.) is raised in the vertical line L R G. But when it reaches R, the projecting piece R disengages the ram from the cross piece B, by striking the bar Q; and as the weight is removed from the extremity D of the lever, the counterpoise I brings it back from G to its old position at F, and the ram falls without interfering with the chain. When the hook is descending, it is prevented from catching the rope by means of the piece of wood N suspended from the hook M at O; for being specifically lighter than the iron weight L, and moving with less velocity, it does not come in contact with L till the ram is stopped at the end of its path. When N, therefore, falls upon L, it depresses the extremity M of the hook, and therefore brings the hoop over one of the cross pieces B, by which the ram is again raised.

The pile engine offers a remarkable confirmation of the doctrine of percussion, proving that, physically speaking, we may balance any percussive force by an equivalent one of mere pressure, or even we may make the latter greater so as to overcome the former. It has, for instance, been found, that in driving piles in a uniform sandy soil of the same density to 47 feet, the piles could not be driven more than 15 feet by any percussive blow that could be communicated by the engine; that is, the friction and resistance of the soil which may be considered as a pressive force, was greater than any percussion force that could be employed by the pile engine, although the rammers made use of were extremely great. And hence when we are computing the effect of a pile engine, it will be necessary to estimate first the quantity of percussion that is equivalent to the resistance and friction opposed to the pile; as no momentum short of this, or even just equal to it, will produce any effect, and when the momentum is greater than this, it is only the difference between the two that is effective in producing motion in the pile. And to this circumstance must be attributed the many erroneous solutions that appeared a few years back to the question, "What must be the height of a pile engine to produce the greatest effect in a given time?" This question, at first sight, appears to be the same with asking how high must the pile engine be to produce the greatest momentum in a given time; but using this principle, the solution always gave the height = 0; that is, the greatest effect will be produced when the rammer is left at rest on the top of the pile. But if instead of proceeding thus, we first estimate, or find from experiment, the height to which the rammer must be drawn, in order that its momentum may be equivalent to the resistance of the pile, and then considering the difference between this and any greater momentum to be only the effective part, a very rational solution will be obtained. But before entering upon the solution of this problem, it will be proper to offer a few farther remarks with regard to the comparability of percussion

and pressure, because the solution ultimately depends upon a proper comparison of those quantities, and a want of due attention to which seems to have been the cause of the erroneous results generally deduced in the solution of this problem. Without, indeed, entering into a discussion concerning the congruity or incongruity of these forces, it is obvious that they may be so employed as to produce the same or equal results. A nail, for example, may be driven to a certain depth into a block of wood by the blow of a hammer, or it may be sunk to the same depth by the pressure of a heavy body; whence, and from numerous other instances, it is obvious that pressure and percussion, whether congruous or incongruous in their nature, are at least comparable in their effects. With regard to the above problem, the resistance and friction of the soil against the pile may, as above observed, be considered as a pressure, and the object of our inquiry is, to establish a comparison between this resistance and pressure of the soil, and the momentum of the ram, or what part of the whole generated momentum of the latter is employed in overcoming the resistance of the former, in order to determine the effective part of the stroke, which ought alone to be considered in estimating the maximum effect; because any single momentum, less than that which is equivalent to the resistance, would produce no effect whatever. Now it being admitted that pressure and momentum are at least comparable in their effects, it must also be granted that there is some determinate momentum of the ram equivalent to the resistance of the pile; and the height necessary for producing this momentum must be the first object of our research, which it is obvious, from various circumstances that may arise in the application of the engine, can only be determined by experiment.

PILLOW, a block of timber whereon the inner end of the bowsprit is supported.

PILOT, the officer who superintends the navigation, either upon the sea coast or upon the main ocean. It is, however, more particularly applied to the person charged with the ship's course on or near the sea-coast, and into the roads, rivers, bays, havens, &c. within his particular district. The regulations with regard to pilots in the royal navy are as follow:—The commanders of the king's ships, in order to give all reasonable encouragement to so useful a body of men as pilots, and to remove all objections to his majesty's service, are strictly charged to treat them with good usage, and an equal respect with warrant officers. The purser of the ship is always to have a set of bedding provided on board for the pilots, and the captain is to order the boatswain to supply them with hammocks, and a convenient place to lie in near their duty, and apart from the common men; which bedding and hammocks are to be returned when the pilots leave the ship. A pilot, when conducting one of his majesty's ships in pilot water, shall have the sole charge and command of the ship, and may give orders for steering; setting, trimming, or furling the sails; tacking the ship, or whatever concerns the navigation; and the captain is to take care that all the officers and crew obey his orders. But the captain is diligently to observe the conduct of the pilot, and if he judges him to behave so ill as to bring the ship into danger, he may remove him from the command and charge of the ship, and take such measures for her preservation as shall be judged necessary; remarking upon the log book the exact hour and time when the pilot was removed from his office, and the reasons assigned for it. Captains of the king's ships employing pilots in foreign parts of his majesty's dominions, shall, after performance of the service, give a certificate thereof to the pilot, which being produced to the proper naval officer, he shall cause the same to be immediately paid; but if there be no naval officer there, the captain of his majesty's ship shall pay him, and send him the proper vouchers, with his bill, to the navy board, in order to be paid as bills of exchange. Captains of his majesty's ships employing foreign pilots to carry the ships they command into or out of foreign ports, shall pay them the rates due by the establishment or custom of the country, before they discharge them; whose receipts being duly vouched, and sent with a certificate of the service performed to the navy board, they shall cause them to be paid with the same exactness as they do bills of exchange.

Branch PILOT, is one who is duly authorized by the Trinity Board to pilot ships up particular channels or rivers.

PIMENTO, Jamaica pepper, or allspice. See MYRTUS.

PIN, in Commerce, a little necessary instrument made of brass wire, chiefly used by women in adjusting their dress. When the wire is received at the manufactory, it is wound off from one wheel to another, and passed through a circle of a smaller diameter in a piece of iron. When reduced to its proper size, it is straightened by drawing it between iron pins, fixed in a board in a zigzag manner. It is afterwards cut into lengths of about four yards, and then into smaller pieces, every length being sufficient for six pins. Each end of these is ground to a point. This operation is performed by boys, who each sit with two small grindstones before him turned by a wheel. Taking up a handful, he applies the wires to the coarsest of the two stones, moving them round that the points may not become flat. He then gives them a smoother and sharper point on the other stone: a lad of 12 years of age can point 16,000 in an hour. When the wire is pointed, a pin is taken off from each end, till it is cut into six pieces. The next operation is to form the heads or head-spinnings, as it is termed. This is done by a spinning wheel: one piece of wire is with rapidity wound round another; and the interior one being drawn out, leaves a hollow tube between the circumvolutions. It is then cut by shears, every two turns of the wire forming one head. These are softened by throwing them into iron pans, and placing them in a furnace till they are red hot. As soon as they are cold, they are distributed to children, who sit with anvils and hammers before them. These they work with their feet by means of a lathe. They take up one of the lengths, and thrust the blunt end into a quantity of the heads which lie before them; catching one at the extremity, they apply it immediately to the anvil and hammer, and by a motion or two of the foot, the point and the head is fixed together in much less time than can be described, and with a dexterity that can only be acquired by practice. The pins are thrown into a copper containing a solution of tin and wine lees. Here they remain for some time, and when taken out assume a dull white appearance: in order to give them a polish, they are put into a tub containing a quantity of bran, which is set in motion by turning a shaft that runs through its centre, and thus, by means of friction, the pins become entirely bright. They are now separated from the bran, which is performed by a mode exactly similar to the winnowing of corn; the bran flying off, and leaving the pin behind it fit for sale.

Needles are made of steel. The first thing in the manufacture of needles, is to pass the steel through a coal fire, and under a hammer to bring it to a round form, then it is drawn through a large hole of a wire-drawing iron, and returned into the fire, and again drawn through a second hole smaller than the first, and thus successively till it has acquired a degree of fineness requisite; observing every time it is drawn to rub it with lard to render it more manageable. The steel thus reduced, is cut to the proper length of the needles; these pieces are flattened at one end to form the eye; they are then put into a fire to soften; then taken out, and the head pierced by a punchon of well-tempered steel, and laid on a leaden block, to bring out, with another punchon, the little piece of steel remaining in the eye. The corners of the heads are then filed off, and a little cavity filed on each side of the flat of the head, the point is then formed with a file, and the whole is filed over. They are then laid on a long narrow iron, crooked on one end, to heat red-hot, with charcoal fire; when taken out, are thrown into a basin of cold water to harden. On this operation much depends; too much heat burns them, too little leaves them soft; experience teaches the medium. When thus hardened, they are laid in a shovel on a fire more or less brisk. This tempers them, and takes off their brittleness. They are then straightened one after another with a hammer. The next process is the polishing. The people take 12 or 15,000 needles, and range them in little heaps on a piece of new buckram sprinkled with emery dust; they are then sprinkled with oil of olives. The whole is then made up in a roll, and laid on a polishing table: a thick plank is now passed over the whole, and the needles within become polished. They are then washed in water with soap, and wiped in bran. The good are taken from the bad; the points are tipped with an emery stone turned by a wheel, and then packed up in parcels of 250 each for sale.

PIN OF A BLOCK, is the axis on which the sheaves revolve being supported by the shell. *Belaying PINS*, pieces of wood or iron fixed in a kind of rail for making fast the small running rigging.

PINCHBECK, a factitious metallic substance, being an alloy of zinc three parts, and of copper four.

PINE, the *Fir Tree*. Its timber, under the name of deal, is employed as wood-work for the building of houses; for rafters, flooring, doors, the frames of windows, tables, boxes, and other purposes infinitely too various to be enumerated. Frigates, and other ships of large size, have sometimes been constructed of deal; but these are by no means so durable as those built of oak. Much of the deal which we use is imported into this country from Norway, and other northern parts of Europe. That from Christiana, which in London is called yellow deal, and in the country red deal, is frequently brought over in planks, but more commonly in boards about ten inches and half in width. The Scots fir raised in England is equal to the foreign wood in weight and durability, but its grain is generally coarser. We are informed that in some parts of Ireland the bogs are almost entirely filled with the old roots of the Scots fir; and that these are dug up and converted into ropes, which, for sustaining moisture without decay, are found preferable to ropes made of hemp. The outer bark of the fir-tree may be used in the tanning of leather; and it is said that in the northern parts of Europe the soft, white, and fibrous inner bark is, in times of scarcity, made into a kind of bread. For this purpose it is dried over a fire, reduced to powder, kneaded with water and a small portion of corn flour into cakes, and baked in an oven. Children in Norway are very fond of the fresh bark in the spring of the year, either shaved off with a knife or grated with a rasp.

Common turpentine is the resinous juice chiefly of the Scots fir, obtained by boring holes into the trunks of the trees early in spring, and placing vessels beneath for its reception. It is of a brown colour, and has a strong odour and disagreeable taste. On the distillation of turpentine, an essential oil is produced, called oil of turpentine, which is extremely pungent. When the distillation is continued to dryness, that which is left behind is known by the name of common resin or rosin; but if water be mixed with it while yet fluid, and incorporated by violent agitation, a substance is formed called yellow resin. Common turpentine is mostly employed as an ingredient in the plasters used by farriers. The oil is occasionally used in medicine; and lately it has been considered efficacious in cases of worms. It is much employed by painters for rendering their colours more fluid; as well as in the composition of different kinds of varnish used in floor-cloth, umbrella, and other manufactures. The noxious spirit called gin was formerly flavoured with juniper berries; but as these are now too expensive, oil of turpentine, the taste of which in a slight degree resembles that of juniper, is applied to the same purpose; and very considerable quantities of turpentine are thus consumed. The common resin is used in plasters, for which its great adhesiveness renders it peculiarly applicable. It is also of considerable importance in the arts; and musicians rub the bows and strings of violins with it, to take off the greasy particles which are there collected, as well as to counteract the effects of moisture. Yellow resin is used in plasters, and for other purposes in medicine. Tar is obtained from the roots and refuse parts of the fir-tree by cutting them into billets, piling these in a proper manner in pits or ovens formed for the purpose, covering them partly over, and setting them on fire. During the burning, a black and thick matter, which is the tar, falls to the bottom, and is conducted thence into vessels which are placed to receive it, and from which it is afterwards poured into barrels for sale. Tar is an article of great utility in manufactures, and for various economical purposes. It is much employed for snecaring the rigging and other external parts of ships, to prevent their receiving injury from moisture. It has been used in medicine both internally and externally; and particularly tar water, or water impregnated with tar.

The *Weymouth Pine*, is chiefly distinguished by its leaves growing in fives; and its cones being smooth, cylindrical, and longer than the leaves. This species grows wild in North America, and succeeds well in strong land in England. Its tim-

ber is white, of more open grain than Scots fir, and not so heavy as that. In America it is principally used for the masts of ships, for which by its toughness it is peculiarly calculated.

The *Scotch Fir*, *PINUS SYLVESTRIS*, a very useful tree in plantations for protecting other more tender sorts when young. It is also now very valuable as timber:—necessity, the common parent of invention, has taught our countrymen its value. When foreign deal was worth twenty pounds per load, they contrived to raise the price of this to about nine or ten pounds, and it was then thought proper for use; before which period, and when it could be bought for little money, it was deemed only fit for fuel. On the South Downs some plantations of this tree, which have been sold after twenty-five years' growth, at a price which averaged a profit of twenty shillings per annum per acre, on land usually let for sheep-pasture at one shilling and sixpence.

The *Spruce Fir*, *PINUS ABIES*, a native of Norway, and other northern parts of Europe, is known by its short and four-sided leaves, growing singly, and surrounding the branches, its cones being cylindrical, the scales somewhat square, flattened and notched at the top. The wood of the spruce fir is what the English carpenters usually denominate white deal. It is considered next in value to that obtained from the Scots fir; and is remarkable for having few knots. On account of its lightness, it is peculiarly adapted for packing cases and musical instruments.

PINION, in Mechanics, an arbor or spindle, in the body of which are several notches, which catch the teeth of a wheel that serves to turn it round; or it is a lesser wheel that plays in the teeth of a larger one.

PINK, a vessel used at sea, masted and rigged like other ships, only that this is built with a round stern; the bends and ribs compassing so as that her ribs bulge out very much. This disposition renders the pinks difficult to be boarded, and also enables them to carry greater burdens than others, for which purpose they are often used.

PINNA, in Zoölogy, a genus belonging to the order of vermes testacea. The animal is a slug.

PINNACE, a small vessel used at sea, with a square stern, having sails and oars, and carrying three masts, chiefly used as a scout for intelligence, and for landing of men, &c. One of the boats belonging to a great man of war, serving to carry the officers to and from the shore, is also called the pinnace.

PINNACLE, in Architecture, the top or roof of a house to minating in a point.

PINTLES, certain pins or hooks fastened upon the back part of the rudder, with their points downwards, in order to enter into and rest upon the googings fixed on the stern post to support the rudder. See the article **HELM**.

PINUS, the *Fir*. See **PINE**.

PIONEERS, in the art of war, are such as are commanded in from the country, to march with an army for mending the ways, for working on entrenchments and fortifications, and for making mines and approaches.

PIP, or **PEP**, *pepia*, a disease among poultry, consisting of a white thin skin, or film, that grows under the tip of the tongue, and hinders their feeding.

PIPE, in Law, a roll in the Exchequer, otherwise called the *Great Roll*.

PIPE also denotes a vessel or measure for wine, containing 126 gallons.

PIPE Office, is an office wherein a person, called the clerk of the pipe, makes out leases of crown lands, by warrant from the lord treasurer, or commissioners of the treasury, or chancellor of the exchequer. The clerk of the pipe makes out also accounts of sheriffs, &c. and gives the accomptants their *quietus est*.

PIPER, *Pepper*, a genus of the trigynia order, in the dianthia class of plants. There is no calix or corolla; the berry is one-seeded. There are 60 species.

PIPES, for conveying of water, for pumps, water-engines, &c. are usually of lead, iron, earth, or wood; the latter are usually made of oak or elder. Those of iron are cast in forges; their usual length is from six to eight feet; several of these are commonly fastened together by means of four screws at each

end, with leather or old hat between them, to stop the water. Those of earth are made by the potters; these are fitted into one another, one end being always made wider than the other. To join them the closer, and prevent their breaking, they are covered with tow and pitch: their length is usually about that of the iron pipes. The wooden pipes are trees bored with large iron augurs of different sizes, beginning with a less, and then proceeding with a larger, successively; the first being pointed, the rest being formed like spoons, increasing in diameter from one to six inches, or more; the pipes are fitted into the extremities of each other, as here represented, and are sold by the

foot. Wooden pipes are bored, either by a borer advancing horizontally, while the wood to be pierced is turned round, in some such manner as in boring of ordnance; or, by causing the timber to be gradually advanced, while the borer turns round; the latter method is the most common. The apparatus most frequently adopted, when the first mover is a stream of water, is that invented by M. Morel.

This machinery, (see Plate *Pile Engines*, &c.) is represented at fig. 6, where the vertical wheel A is put into motion by water descending upon it through a trough or sloping canal: upon the horizontal axle of this wheel is a cog wheel B, which gives motion to the lanterns C, D, the common axis of these lanterns being in a vertical position. The lantern D turns at the same time two cog wheels E and F; the first, E, which is vertical, turns the augur that bores the wood; and the second, F, which is horizontal, has attached to it by a pin which is at a small distance from its centre, a lever or arm H, with a hook at its end, taking into the indentations of one of the wheels of the carriage that carries the wood to be bored. Another lever, I, hanging upon the former, is prevented from falling by a spring, and pushes by its extremity against the notches of the lower end of the same wheel. Thus, as the cog wheel turns round, the carriage-wheel is first pulled forward by the hook and lever H, and then pushed backward as far by the arm I; by this means causing a pinion upon the axle of the carriage wheel to advance the rackwork above it, together with the timber to be bored; so that the timber is advanced by a slight reciprocating motion of the carriage. The augur, being generally some feet in length, plays in holes in two pieces L, L, which retain it in its horizontal position, and thus it forms a cylindrical cavity in the wood, as required.

PIPES, *Tobacco*, are made of various fashions; long, short, plain, worked, white, varnished, unvarnished, and of various colours, &c.

PIPER, the *Manakin*, a genus of birds of the order of passer. Latham describes 25 species, and five varieties.

PIRACY, is the seizing or plundering a vessel on the high seas, without having a commission for that purpose.

PIRATE, a sea robber. By stat. 28. Hen. VIII. c. 15. all treasons, felonies, robberies, murders, and confederacies, committed upon the sea, or in any haven, creek, or place, where the admiral has jurisdiction, shall be tried in such shires or places as the king shall appoint by his commission, in like forms as if such offence had been committed upon land, and according to the course of the common law, and the offenders shall suffer death, without benefit of clergy. And by stat. 6 Geo. I. made perpetual, it is enacted, that if any of his majesty's natural born subjects, or denizens of this kingdom, shall commit any piracy or robbery, or any act of hostility, against other his majesty's subjects upon the sea, under colour of any commission from any prince or state, or pretence of authority from any person whatsoever, such offender shall be deemed to be a pirate, felon, and robber; and being duly convicted thereof, according to this act, or the aforesaid act of 23 Hen. VIII. shall have and suffer such pains of death, loss of lands, goods, and chattels, as pirates, felons, and robbers upon the seas, ought to have and suffer. By 18 Geo. II. c. 30. persons committing hostilities, or aiding enemies at sea, may be tried as pirates. Piracies at sea are excepted out of the general pardon, by 20 Geo. II. c. 52.

PIRATE'S Goods go to the admiral by grant; but not piratical goods, which go to the king, if the owner is not known.

PISCES, the *Fishes* ♋, are the last of the signs in the fixed zodiac, and consequently the last of the Southern and Winter signs: the sun enters it about the 19th of February, and the earth is then just entering into the sign Virgo. Reckoning, however, by the visible zodiac, this sign has taken the place of Aries, and it is chiefly situated on the north side of the equator; the *Fishes* have therefore become the leaders of the celestial hosts; and on all artificial representations of the heavens, wherein the constellations are laid down according to their recession from the vernal equinox, as established by the intellectual zodiac of Hipparchus, the Sun actually enters Pisces about the 6th of March.

PISCES, *Fishes*, in Natural History, is the fourth class in the Linnæan system, consisting of five orders, viz. Abdominales, Apodes, Cartilaginii, Jugulares, and Thoracici. The class is described as having incumbent jaws; eggs without white; organs of sense; for covering, imbricate scales; fins for supporters; they swim in water; respiration is performed by means of gills, which supply the place of lungs. Air is equally necessary to the existence of fish, as it is to other animals. This process, in fishes, as breathing in the human subject, is carried on during sleep, and is repeated about twenty-five times in a minute; and the necessity of it is evinced, from the circumstance of fish being certainly killed in water, from which air is taken away by means of the air-pump, or excluded by very severe frost. Should the free play of the gills be even suspended, or their covers kept from moving, by a string tied round them, the fish would fall into convulsions, and die in a few minutes. It is said, likewise, that though the branchial apparatus be comprised in a small compass, its surface, when fully extended, would occupy many square feet; a fact, that may convince the most sceptical, of the numberless convolutions and ramifications in which the included water is elaborated and attenuated, in the course of giving out its air in the respiratory process. Fishes have the organs of sense, some of them probably in a very high degree, and others imperfectly; of the latter kind, are the senses of touch and of taste; but the sense of hearing has now been completely ascertained, which was long doubted, and by some physiologists denied: the organ is contained in the cavity of the head. The organ of smelling is large, and the animals have a power of contracting and dilating the entry to it as they have occasion. It seems to be mostly by their acute smell that they discover their food, for their tongue seems not to have been designed for a very nice sensation, being of a pretty firm cartilaginous substance; and common experience evinces, that their sight is not of so much use to them as their smell in searching for their nourishment.—We now proceed to notice the motion of fishes, for the celerity of which their shape is admirably adapted: hence, vessels designed to be navigated in water, are made to imitate, in some degree or other, the shape of fish; but the rapidity of a ship in sailing before the wind, is not to be compared to the velocity of a fish. The largest fishes are known to overtake a ship in full sail with the greatest ease, to play round it without effort, and to surpass it at pleasure. Every part of the body seems formed for despatch: the fins, the tail, and the motion of the whole backbone, assist in the business; and it is to that flexibility of body which mocks the efforts of art, that fishes owe the great velocity of their motions. The chief instruments in a fish's motion are its fins, air-bladder, and tail; with two pair, and three single fins, it will migrate a thousand leagues in a season, and without indicating any visible symptoms of languor or fatigue. By means of the air bladder, fishes can increase or diminish the specific gravity of their body. When they contract it, and press out the air, the bulk of the body is diminished, and the fish sinks as far as it pleases: on relaxing the operation, the bladder acquires its natural size, the body becomes specifically lighter, and the fish is enabled to swim near the surface. The tail, in the last place, may be regarded as the rudder, directing the motions of the fish, to which the fins are only subservient. With respect to the nourishment of fishes: they are mostly carnivorous, though they seize upon almost any thing that falls in their way, and not uncommonly devour their own offspring; they seem, indeed, to manifest a particular predilection for whatever they can swallow possessed of life. Fishes can, however, notwithstanding their natural

voracity, live long, apparently, without food; but they, perhaps, in vases and other ornamental vessels, feed on insects too small for the human eye to see; or, it has been thought, they may have the power of chemically decomposing water. A few species of fishes, as the eel, blenny, &c. are viviparous; but by far the greater number are produced from eggs. Fishes have different seasons for depositing their spawn. Some, which live in the depths of the ocean, are said to choose the winter months; but, in general, those with which we are acquainted, choose the hottest months in summer, and prefer such water as is somewhat tepid by the beams of the sun. They then leave the deepest parts of the ocean, which are the coldest, and shoal round the coasts, to swim up the fresh water rivers, which are warm as they are comparatively shallow, depositing their eggs where the sun's influence can most easily reach them, and seeming to take no farther charge of their future progeny. Of the eggs thus deposited, scarcely one in a hundred brings forth an animal, as they are devoured by all the lesser fry which frequent the shores, by aquatic birds near the margin, and by the larger fish in deep water. Still, however, the sea is amply supplied with inhabitants; and notwithstanding their own rapacity, and that of various tribes of fowls, the numbers that escape are sufficient to relieve the wants of a considerable portion of mankind. Indeed, when we consider the fecundity of a single fish, the amount will seem astonishing. If we should be told, for example, that a single being could in one season produce as many of its kind as there are inhabitants in England, it would strike us with surprise; yet the cod annually spawns, according to Lewenhoeck, above nine million of eggs contained in a single roe. The flounder is commonly known to produce above one million; and the mackerel above five hundred thousand; a herring of a moderate size, will yield at least ten thousand; a carp, of fourteen inches in length, contained, according to Petit, two hundred and sixty-two thousand two hundred and twenty-four; and another, sixteen inches long, contained three hundred and forty-two thousand one hundred and forty-four; a perch deposited three hundred and eighty thousand six hundred and forty; and a female sturgeon, seven million six hundred and fifty-three thousand two hundred. The viviparous species are by no means so fruitful; yet the blenny brings forth two or three hundred at a time, all alive and playing round the parent together.

PISCIS AUSTRALIS, the *Southern Fish*, is one of the old constellations, the brilliant of which was a subject of great study by the Egyptians and Ethiopians, as I have already observed. The river of Aquarius is lost at the mouth of the Fish, as our astronomers depict the constellations. The brilliant Fomalhaut is nearly on the same meridian with Markab in Pegasus; but Kircher's Planispheres are destitute of this symbol; yet we may conceive its high antiquity from the place it holds among the celestial host, and its relation with Aquarius.

PISCIS VOLANS, the *Flying Fish*, situated on the Antarctic circle, contains eight stars all under the 4th magnitude.

PISOLIT, a mineral found at Carlsbad, in Bohemia. It has the form of round masses composed of concentric layers, and containing a grain of sand in their centre. Colour white, often grayish, reddish, or yellowish.

PISTOLE, a Spanish gold coin, of which there are quadruple, double, and half pistoles.

PISTON, in Mechanics, denotes a short cylinder working within another hollow cylinder, as in water or air pumps, and some other machines.

PISUM SATIVUM. (*The Pea*.) The gray hog pea used to be the only one sufficiently hardy for culture in the fields; but since the improvement of our agriculture, we have all the finer varieties cultivated in large quantities. The seed used is about two bushels and a half per acre, and the produce varies from three to ten quarters. The varieties of peas are many, but the principal ones used in agriculture are the early Charlton pea; the Dwarf marrow; the Prussian blue. All these are dwarf kinds, and as the demand for this article in war time is great for the navy and army, if the farmer's land will suit, and produce such as will boil, they will fetch a considerably greater price in proportion. The varieties that are found to boil are either used whole, or split, which is done by steeping them in water till the cotyledons swell, after which they are dried on a

kiln, and passed through a mill; which just breaking the husk, the two cotyledons fall apart.

PITCH, a tenacious oily substance, drawn chiefly from pines and firs, and used in shipping, medicine, and other arts; or it is more properly tar, inspissated by boiling it over a slow fire.

PITCH, *Minéral*, has a strong resemblance to common pitch. Colour black, dark brown, or reddish. Specific gravity from 1.46 to 2. Does not stain the fingers. On a white iron it flames with a strong smell, and leaves a quantity of gray ashes.

PITCHING, is the vertical vibration which the length of a ship makes about her centre of gravity, or the moment by which she plunges her head and afterpart alternately into the hollow of the sea. This motion may proceed from two causes; the waves which agitate the vessel, and the wind upon the sails which makes her stoop at every blast. The first absolutely depends upon the agitation of the sea, and is not susceptible of inquiry; and the second is occasioned by the inclination of the masts, and may be submitted to certain established maxims. When the wind acts upon the sails, the masts yield to its effort with an inclination which increases in proportion to the length of the mast, to the augmentation of the wind, and to the comparative weight and distribution of the ship's lading. The repulsion of the water to the effort of gravity, opposes itself to this inclination, or at least retains it by as much as the repulsion exceeds the momentum or absolute effort of the mast, upon which the wind operates. At the end of each blast, when the wind suspends its action, this repulsion lifts the vessel; and these successive inclinations and repulsions produce the movement of pitching, which is very inconvenient; and when it is considerable, will greatly retard the course as well as endanger the mast and strain the vessel.

PITCHSTONE. This stone, which occurs in different parts of Germany, France, and other countries, has obtained its name from some resemblance which it has been supposed to have to pitch. It is most usually in amorphous pieces of different sizes.

PITH, in Vegetation, the soft spongy substance contained in the central parts of plants and trees.

PIVOT, a foot or shoe of iron, or other metal, usually conical, or terminating in a point, by which a body, intended to turn round, bears on another fixed and at rest, and performs its revolutions. The pivot usually bears or turns round in a sole, or piece of iron or brass, hollowed out to receive it.

PLACE, in Philosophy, that part of immoveable space which any body possesses or occupies, having to space the same relation that time has to duration.

PLACE has various denominations, as *absolute, relative, primary*, &c. which will be readily comprehended without any formal definitions.

PLAGUE, in the time of *Justinian the Emperor*.—The following dismal relation of this dire calamity is given in the eloquent language of Mr. Gibbon.—Ethiopia and Egypt have been stigmatized in every age as the original source and seminary of the plague. In a damp, hot, stagnating air, this African fever is generated from the putrefaction of animal substances, and especially from the swarms of locusts, not less destructive to mankind in their death than in their lives. The fatal disease which depopulated the earth in the time of Justinian and his successors, first appeared in the neighbourhood of Pelusium, between the Serbonian bog and the eastern channel of the Nile. From thence, having as it were a double path, it spread to the east over Syria, Persia, and the Indies, and penetrated to the west, along the coast of Africa, and over the continent of Europe. In the spring of the second year, Constantinople, during three or four months, was visited by the pestilence; and Procopius, who observed its progress and symptoms with the eyes of a physician, has emulated the skill and diligence of Thucydides in the description of the plague of Athens. The infection was sometimes announced by the visions of a dis-tempered fancy; and the victim despaired as soon as he had heard the menace and felt the stroke of an invisible spectre. But the greater number in their beds, in the streets, in their usual occupation, were surprised by a slight fever; so slight, indeed, that neither the pulse nor the colour of the patient gave any signs of the approaching danger. The same, the next, or the succeeding day, it was declared, by the swelling of the glands, particularly those of the groin, of the arm-pits,

and under the ear; and, when these buboes or tumors were opened, they were found to contain a *coal* or black substance of the size of a lentil. If they came to a just swelling and suppuration, the patient was saved by this kind and natural discharge of the morbid humour. But, if they continued hard and dry, a mortification quickly ensued, and the fifth day was commonly the term of his life. The fever was often accompanied by lethargy or delirium; the bodies of the sick were covered with black pustules or carbuncles, the symptoms of immediate death; and, in the constitutions too feeble to produce an eruption, the vomiting of blood was followed by the mortification of the bowels. To pregnant women the plague was generally mortal. Youth was the most pernicious season, and the female sex was less susceptible than the male; but every rank and profession was attacked with indiscriminate rage; and many of those who escaped were deprived of the use of their speech, without being secure from a return of the disorder. The physicians of Constantinople were zealous and skilful, but their art was baffled by the various symptoms and pertinacious vehemence of the disease: the same remedies were productive of contrary effects, and the event capriciously disappointed their prognostics of death or recovery. The order of funerals and right of sepulchres were confounded; those who were left, without friends or servants lay unburied in the streets, or in their desolate houses; and a magistrate was authorized to collect the promiscuous heaps of dead bodies, to transport them by land or water, and to inter them in deep pits beyond the precincts of the city. Their own danger, and the prospect of public distress, awakened some remorse in the minds of the most vicious of mankind; the confidence of health again revived their passions and habits. The plague had touched the person of Justinian himself. During his sickness, the public consternation was expressed in the habits of the citizens, and their idleness and despondency occasioned a general scarcity in the capital of the East. Contagion is the inseparable symptom of the plague, which, by mutual respiration, is transfused from the surfeited persons to the lungs and stomach of those who approach them. While philosophers believe and tremble, it is singular that the real danger should have been denied by a people most prone to vain and imaginary terrors (the French.) Yet, the fellow-citizens of Procopius were satisfied, by some short and partial experience, that the infection could not be gained by the closest conversation; and this persuasion might support the assiduity of friends and physicians in the care of the sick, whom inhuman prudence would have condemned to solitude and despair. But the fatal security, like the predestination of the Turks, must have aided the progress of the contagion; and those salutary precautions, to which Europe is indebted for her safety, were unknown to the government of Justinian. No restraints were imposed on the free and frequent intercourse of the Roman provinces; from Persia to France the nations were mingled and infected by wars and emigrations; and the pestilential odour, which lurks for years in a bale of cotton, was imported, by the abuse of trade, into the most distant regions. The mode of its propagation is explained by the remark of Procopius himself, that it always spread from the sea-coast to the inland countries: the most sequestered islands and mountains were successively visited; the places which had escaped the fury of its first passage, were alone exposed to the contagion of the ensuing year. The winds might diffuse that subtle venom; but, unless the atmosphere be previously disposed for its reception, the plague would soon expire in the cold or temperate climates of the earth. Such was the universal corruption of the air, that the pestilence, which burst forth in the 15th year of Justinian, A.D. 542, was not checked or alleviated by any difference of the seasons. In time its first malignity was abated and dispersed; the disease alternately languished and revived; but it was not till the end of a calamitous period of fifty-two years that mankind recovered their health, or the air resumed its pure and salubrious quality. No facts have been preserved to sustain an account, or even a conjecture, of the numbers* that perished in this extraordinary mortality. I only find that, during three

* It is probable that no less than an hundred millions of human beings fell victims to this contagion in the Roman empire alone !!!

months, five, and at length ten, thousand people died each day at Constantinople; that many cities of the East were left vacant; and that, in several districts in Italy, the harvest and the vintage withered on the ground. The triple scourge of war, pestilence, and famine, afflicted the subjects of Justinian; and his reign is remarkable for a visible decrease of the human species, which has never been repaired, in some of the fairest countries of the globe.

PLAGUE Water, one of the compound waters of the shops, distilled from mint, rosemary, angelica roots, &c.

PLAIN, in general, an appellation given to whatever is smooth and even, or simple, obvious, and easy to be understood; and consequently, stands opposed to rough, enriched, or laboured. A plain figure, in geometry, is an uniform surface, from every point of whose perimeter, right lines may be drawn to every other point in the same. A plain angle is one contained under the two lines or surfaces, in contradistinction to a solid angle. The doctrine of plain triangles, as those included under three right lines, is termed plain trigonometry.

PLAIN Number, is a number that may be produced by the multiplication of two numbers into one another; thus 20 is a plain number produced by the multiplication of 5 into 4.

PLAIN, *Place*, *locus planus*, or *locus ad planum*, among the ancient geometers, denoted a geometrical locus, when it was a right line or a circle, in opposition to a solid place, which was an ellipsis, parabola, or hyperbola.

PLAIN Problem, in Mathematics, is such a problem as cannot be solved geometrically, but by the intersection either of a right line and a circle, or of the circumferences of two circles; as, given the greatest side, and the sum of the other two sides of a right-angled triangle, to find the triangle, as also to describe a trapezium that shall make a given area of four given lines.

PLAIN Table, in Surveying, a very simple instrument, whereby the draught of a field is taken on the spot, without any future protraction.

PLAN, in general, denotes the representation of something drawn on a plane, such as maps, charts, ichnographies, &c.

PLANE. See GEOMETRY.

PLANE, is a term used by shipwrights, implying the area or imaginary surface contained within any particular outlines, as, the plane of elevation, the plane of projection, the horizontal plane.

PLANE, in Joinery, an edged tool, or instrument, for paring and shaving of wood smooth.

PLANET, a wandering star, as distinguished from the fixed stars, which always preserve the same relative position with respect to each other. Hence it follows that comets and satellites are included, according to the original signification of this term, under the same general denomination; in fact, the early astronomers had no idea of comets being permanent bodies, and as they were also unacquainted with any satellite but the moon, which with the sun was supposed to revolve about the earth, it was natural for them to class both under the same general appellation. But modern astronomers, in order to make a distinction between these, define a planet to be a celestial body revolving about the sun as a centre, with a moderate degree of eccentricity; thus excluding comets, the eccentricity of whose orbits is very considerable, and the satellites, which revolve about their primaries as the primaries do about the sun. These last are, however, sometimes called secondary planets. See ASTRONOMY.

We have given, under the several articles ECCENTRICITY, DISTANCE, ORBIT, PERIOD, &c. the several particulars included under those denominations, as also under the names of the several planets, the respective elements of each; and we have therefore, in this place, only to state a few popular observations relative to the probable nature, motion, appearances, &c. of these celestial bodies; and to give a general view of the elements and other particulars of the planetary system. First, then, all the planets perform their revolutions in elliptical orbits about the sun, which is situated in one of the foci of the ellipse; the orbit of each planet lies in a plane, which passes through the centre of the sun; those which are nearest the centre move with a greater velocity than those that are more remote; the same planet is also quicker or slower according as it is in that part of its orbit which is nearer or more remote from the central body; and all their motions are performed in the same order

from west to east, or according to the order of the signs. The motions and distances of the several planets are related to each other by invariable laws, viz. that the cubes of their periodic times of revolution, are as the squares of their distances from the sun; and that equal areas are described by the same planet in equal times; that is, if we suppose a line drawn from the sun to a planet, and to move about it as a centre, that line will pass over or describe equal areas in equal times; therefore since the periods of the planetary revolution are accurately known from observation, we may hence find the exact proportional distance of all these bodies. See KEPLER'S LAWS.

It has been discovered by means of spots, observable on the discs of the planets, that they have a rotatory motion about their own axes, the time of which, however, seems to follow no particular law either with regard to their magnitude or distance from the sun. Hence it appears that these bodies have each a diversity of seasons, their spring, summer, autumn, and winter, resembling those in our planets; they have likewise the same alternations of day and night, and in short, that they are fitted to the accommodation of inhabitants.

"With constitutions fitted to the spot

Where Providence all-wise has fixed their lot."

The excessive heat and cold experienced in those regions, in consequence of their proximity or remoteness from the sun, as have been supposed and even computed by some authors, appear to be wholly imaginary. Uranus, the most distant planet in our system, has a temperature perhaps not at all different from Mercury, who revolves much nearer to the sun than ourselves. The light and heat received and experienced in our globe, seems to depend more upon the constitution of the atmosphere than any other cause; or why have we mountains covered with perpetual snow, and whence that diminution of light and heat experienced by aerial voyagers, but in consequence of the extreme rarity of the air in the upper regions? and if this be granted, it follows immediately that a simple modification in the atmospheres of the several planets, would render the temperature of each supportable even by terrestrial inhabitants.

The idea of the temperature of the several planets depending upon their distances from the sun, arises from considering that body, not simply as the cause of heat, but as an immense mass of fire, possessing in itself, independent of any other agent, the power of heat; whereas there is every reason to conclude that it is only by a combination of the solar rays with certain parts of our atmosphere that the effect is produced. Water poured upon unslacked lime generates heat in the combined mass, and if we could imagine a being existing in such a mass, we should have no difficulty in conceiving that he would attribute that quality to the water, which we attribute to the sun, although in this case the contrary is evident. We cannot doubt then, without presumptuously limiting the power and wisdom of the Deity, that each of these planets is peopled with millions of beings engaged like us in the anxious vicissitude of life, and probably each having its philosophers and astronomers contemplating this immense globe as a mere speck in the starry firmament. Nor must we stop here; it is also highly probable that every fixed star is another centre, about which planets are revolving, as those of our system do about the sun. Instead therefore of one sun and one world, as the ignorant imagine, reason and contemplation point out to us millions of suns and millions of worlds, each peopled by myriads of inhabitants, dispersed through infinite space, to which our system appears but as a mere point or atom, and is almost lost in the immensity of the creation.

What an august, what an amazing conception, if human imagination can conceive it, does this give of the works of the Creator! Thousands of thousands of suns multiplied without end, and ranged all round us, at immense distances from each other, attended by ten thousand times ten thousand worlds, all in rapid motion, yet calm, regular, and harmonious, invariably keeping the paths prescribed them; and these worlds peopled with myriads of intelligent beings, formed for an endless progression in perfection and felicity. If so much power, goodness, and magnificence, be displayed in the material creation, which is the least considerable part of the universe, how great, wise, and good must He be, who made and governs the whole!"

Elements of the PLANETS, are certain quantities which are necessary to be known in order to determine the theory of their elliptic motion. Astronomers reckon seven of those quantities, of which five relate to the elliptic motion, viz. 1. The duration of the sidereal revolution. 2. The mean distance or semi-axis major. 3. The eccentricity, from which is derived the greatest equation of the centre. 4. The mean longitude of the planet at any given epoch. 5. The longitude of the perihelion at the same epoch.

The two other elements relate to the position of the orbit, and are, 1. The longitude at a given epoch of the nodes of the orbit with the ecliptic. 2. The inclination of the orbit to this plane.

PLANET Wheels, are wheels by whose mutual connexion a variable angular motion, such as that of the radius vector of a planet in its orbit, may be exhibited. The common contrivance now in use for this purpose was invented, we think, by Desaguliers; it consists of two elliptical wheels, connected either by teeth running into each other, or by a band; these wheels revolve on their foci, and while the driving ellipses move uniformly, the radius vector of the other has the required motion. A much older, and at the same time far better, method than that of Desaguliers, was the invention of M. Joli de Dijon, of which the following is an account. If it be desired to move a wheel of 24 teeth by a pinion of 6, in such a manner that in some parts of its revolution it shall move as swiftly as if it had but 12 teeth, and in other parts as slowly as if it had 48 teeth, the method of accomplishing this is as follows:—

1. Describe the rectangle LMNO, fig. 7, (see *Plate Pile Engines*, &c.) having its side NO equal to the radii of the great wheel, and the pinion taken together, and its breadth LN equal to their thickness; which last must be greater, the more considerable the inequality of the proposed movement. Let NO be so divided in Q, that QO may be to QN, as 6 to 48, that is to say, reciprocally as the velocity of the pinion to the greatest velocity of the wheel. Also divide LM in P, in the proportion of 6 to 12, or reciprocally, as the velocity of the pinion to the least velocity of the wheel. Then join PQ, and draw as many lines SR parallel to LM, as there are intended to be teeth in

the great wheels; upon which write the degrees of velocity they express, which are in the inverse ratio of their lengths.

2. Let two truncated cones be formed in the lathe; one equal to that which would be formed by the revolution of the trapezoid LPQN about LN as an axis; and the other equal to what would be formed by the revolution of the trapezoid PQMO about the axis MO. On the largest of these two cones let the circles generated by the revolution of the points P, T, Q, be marked and distinguished by the same numeral figures as the corresponding parallels of the rectangle LO. Upon the two bases of the conic frustum describe radial lines, which shall make angles at the centre, fig. 9, in the same proportion to each other, as the intended velocities of the wheel, as expressed in fig. 6, and let teeth be cut in the curve surface of the cone corresponding with these lines; after this, look on the circles that express the different velocities, and have been traced on the same surface, to find what part of each tooth ought to remain opposite its corresponding radius, and cut or file the rest away. Thus will the teeth lie in an oblique or elliptical curve, on the conical surface, as is exhibited in the figure by a darker shade. The pinion must be made of a regular conic shape, as is shewn at MO, in fig. 9. By this contrivance, the largest or widest tooth will always meet the largest part of the pinion, and the narrowest will correspond with the smallest part; on which account, though the motion of the pinion be uniform, the wheel will be carried unequally, according to the assigned law; and in a similar manner may planet wheels be described to exhibit any other proposed variation.

PLANETARIUM, an astronomical machine, contrived to represent the motions and various aspects of the heavenly bodies, parallelism of the earth's axis, together with its diurnal motions, and by these means to explain the beautiful variety of the seasons, and other terrestrial and celestial phenomena, has ever been considered as one of the noblest efforts of mechanical genius. Among the variety of machines contrived for these purposes, the *Planetarium*, or *Portable Orrery*, fig. 1, is best adapted for representing the celestial motions.

A planetarium may be considered, in short, as a diametrical section of the universe, in which the upper and lower hemispheres are suppressed. The upper plate is to answer for the ecliptic; on this are placed, in two opposite but corresponding circles, the days of the month, and the signs of the ecliptic, with their respective characters; by this plate you may set the planetary balls so as to be in their respective places on the ecliptic for any day in the year. Through the centre of this plate you observe a very strong stem, on which is a brass ball to represent the sun; round the stem are different sockets to carry the arms by which the several planets are supported.

The planets are represented by ivory balls, having the hemisphere which is next the sun white, the other black, to exhibit their respective phases: and these planets may be taken off, or put on with ease, as occasion may require. About the primary planets are placed the secondary planets, or moons, which are, in some instruments, only moveable by the hand. By turning the handle, all the planets are put in motion, moving round that ball which represents the sun. And, if we take the earth's motion as a standard, the other planets move with the same relative velocities and periodical times with which they traverse through space. The planetarium is furnished with a lamp,

which when it is placed into the socket on which the brass sun is fitted, throws the reflection of the sun's light upon all the planets, and gives their proper phases, &c.

In the Planetarium exhibited in the engraving, ☉ represents the Sun, which is fixed firmly to a wire *a*, and has no motion; ☿ is the planet Mercury, revolving round the Sun; ♀ is the planet Venus; ⊕ represents the Earth, and ☾ the Moon revolving round it; *f* is a segment of brass called the Earth's terminator, which shews that all the parts of the Earth behind it are not illuminated by the Sun; ♄ is the planet Mars; ♃ Jupiter and his four Satellites; ♄ Saturn, with his ring and seven satellites; ♀ Herschel, and six satellites. *L* is a small winch, which when turned gives motion to Mercury and Venus, and shews the Earth's annual motion round the Sun, its diurnal motion, and the Moon's motion round the Earth. The projection in the middle of the circular board *M*, consists of the following parts:—A steel wire *A*, whose lower end is screwed to a bridge under the board, and which carries the Sun; over this is put a tube, on whose lower end a worm wheel, worked by a worm on the arbour of the winch *L* above mentioned, is fixed; and to the upper end the frame of wheels *N*, with the Earth and Moon. Over these is a conical tube, which has a flanch at its lower end, and is fastened to the board *M* by three screws; the arms carrying the planets Mars, Jupiter, Saturn, and Herschel, are fitted stiffly upon this tube, so as not to turn, unless they are moved. These planets do not move by turning the winch, but are to be set by hand, as also their satellites. In the frame of wheels *N*, figs. 1 and 2, *g* is the first wheel, which is fixed to the wire *a*, fig. 1, and is without any motion; this works into another wheel *k* of the same size, fixed to the spindle *i*. The wheel *k* works another wheel *h* of the same size, on whose spindle *y*, fig. 1, the Earth is fixed. Besides the wheel *k*, the spindle *i* has three other wheels *l*, *m*, *n*, fixed on it. The wheel *l* turns *c*, which works a pinion above the wheel *g*, carrying the planet Mercury in fig. 1: this pinion has a hollow spindle, and goes over the wire *a*. The wheel *m* on the spindle *i* works into *p*, which gives motion to the pinion *g*, (whose spindle goes over the spindle of the pinion which carries Mercury,) and has the planet Venus, in fig. 1, fixed to it. The large wheel *n* on the spindle *i* turns, by intermediate wheels, the pinion *S*, whose arbor goes over the spindle carrying the Earth: this has an arm for the Moon fixed to it. The wire *t*, to which the Moon is fixed, slides up and down through a hole in the end of the arm; and the lower end of the wire rests on a circular ring *v*, whose plane is parallel to the plane of the Moon's orbit, so that, as the arm turns round, the wire is pushed up by the inclination of the ring, and falls by its own weight. Beneath this is a ring, with divisions on it, shewing the Moon's age. When the winch *L* is turned, it works the worm wheel beneath the board *M*, and moves the frame *N*, fig. 1, with the Earth round the Sun; and as the wheel *g* is fixed, the wheel *k* is turned by rolling round it; and as *k* (which it works) is of the same size with the other two, it turns the Earth, so that its axis always points to the pole. The wheel *l*, by means of the wheel *c*, turns the pinion, which carries Mercury in fig. 1. The wheel *m*, with the wheel *p*, turns *g*; and the planet Venus in fig. 1, and the wheel *n*, turns the pinion *s*, and the Moon, as before described.

PLANETARY, something that relates to the planets.

PLANETARY System, is the system or assemblage of the planets, primary and secondary, moving in their respective orbits, round their common centre the sun.

PLANIMETRY, that part of geometry which considers lines and plane figures without any regard to heights or depths. **Planimetry** is particularly restricted to the mensuration of planes and other surfaces: as contradistinguished from stereometry or the mensuration of solids, or capacities of length, breadth, and depth.

PLANISPHERE, a projection of the sphere and its various circles on a plane; as upon paper, or the like. In this sense, maps of the heavens and the earth, exhibiting the meridians and other circles of the sphere, may be called planispheres.

PLANISPHERE is sometimes, also considered as an astronomical instrument, used in observing the motions of the heavenly bodies; being a projection of the celestial sphere upon a plane representing the stars, constellations, &c. in their proper

situations, distances, &c. as the astrolabe, which is a common name for all such projections. In all planispheres the eye is supposed to be in a point, viewing all the circles of the sphere, and referring them to a plane beyond them, against which the sphere is as it were flattened; and this plane is called the plane of projection, which is always some one of the circles of the sphere itself, or parallel to some one of them. Among the infinite number of planispheres which may be furnished by the different planes of projection and the different positions of the eye, there are two or three that have been preferred to the rest. Such as that of Ptolemy, where the plane of projection is parallel to the equator; that of Gemma Frisius, where the plane of projection is the colure, or solstitial meridian, and the eye of the pole of the meridian, being a stereographical projection; or that of John de Royas, a Spaniard, whose plane of projection is a meridian, and the eye placed in the axis of that meridian at an infinite distance; being an orthographical projection, and called the analemma.

PLANKING, the act of covering and lining the sides of a ship with planks, which is sometimes by the artificers called laying on the skin. This completes the process of ship-building.

PLANTAGO LANCEOLATA. (*Rib Grass*.) This is a perennial plant, and very usefully grown, either mixed with grasses, or sometimes alone: it will thrive in any soil, and particularly in rocky situations. It is much grown on the hills in Wales, where, by its roots spreading from stone to stone, it is often found to prevent the soil from being washed off, and has been known to keep a large district fertile, which would otherwise be only a bare rock. Sheep are particularly fond of it. About four pounds, sown with other seeds for pasture, will render a benefit in any situation that wants it. Twenty-four pounds is usually sown on an acre when intended for the sole crop, and sown under corn.

PLANTING, in Agriculture and Gardening. The first thing in planting, is to prepare the ground before the trees or plants are taken out of the earth, that they may remain out of the ground as short a time as possible; and the next is to take up the trees or plants in order to their being transplanted. In taking up the trees, carefully dig away the earth round the roots, so as to come at their several parts to cut them off; for if they are torn out of the ground without care, the roots will be broken and bruised, to the great injury of the trees. When you have taken them up, the next thing is, to prepare them for planting, by pruning the roots and heads. And first, prune off all the bruised or broken roots, all such as are irregular and cross each other, and all downright roots, especially in fruit trees, shorten the larger roots in proportion to the age, the strength, and nature of the tree; observing, that the walnut, mulberry, and some other tender-rooted kinds, should not be pruned so close as the more hardy sorts of fruit and forest trees: in young fruit trees, such as pears, apples, plums, peaches, &c. that are one year old from the time of their budding or grafting, the roots may be left only about eight or nine inches long; but in older trees, they must be left of a much greater length; but this is only to be understood of the larger roots, for the small ones must be chiefly cut quite out, or pruned very short.

The next thing is, the pruning of their heads, which must be differently performed in different trees, and the design of the trees must also be considered; thus, if they are intended for walls or espaliers, it is best to plant them with the greatest part of their heads, which should remain on till they begin to shoot in the spring, when they must be cut down to five or six eyes, at the same time taking care not to disturb the roots. But if the trees are designed for standards, you should prune off all the small branches close to the place where they are produced, as also the irregular ones which cross each other; and after having displaced these branches, you should also cut off all such parts of branches as have, by any accident, been broken or wounded; but by no means cut off the main leading shoots, which are necessary to attract from the root, and thus promote the growth of the tree.

Having thus prepared the trees for planting, you must now proceed to place them in the earth; but if the first trees have been long out of the ground, so that the fibres of the roots are dried, place them eight or ten hours in water before they are

planted, with their heads erect, and the roots only immersed in it, which will swell the dried vessels of the roots, and prevent them to imbibite nourishment from the earth. In planting them, great regard should be had to the nature of the soil, for if that is cold and moist, the trees should be planted very shallow, and if it is a hard rock or gravel, it will be better to raise a hill of earth where each tree is to be planted, than to dig into the rock or gravel, and fill it up with earth, as is too often practised, by which means the trees are planted as in a tub, and have but little room to extend their roots.

The next thing to be observed is, to place the trees in the hole in such a manner that the roots may be about the same depth in the ground as before they were taken up; then break the earth fine with a spade, and scatter it into the hole, so that it may fall in between every root, that there may be no hollow-ness in the earth. Having filled up the whole, gently tread down the earth with your feet, but do not make it too hard, which is a great fault, especially if the ground is strong or wet. Having thus planted the trees, they should be fastened to stakes driven into the ground, to prevent their being displaced by the wind, and some mat or laid about the surface of the ground about their roots; as to such as are planted against walls, their roots should be placed about a foot from the wall, to which the heads should be nailed, to prevent their being blown up by the wind. The seasons for planting are various, according to the different sorts of trees, or the soil in which they are planted; for the trees whose leaves fall off in winter, the best time is the beginning of October, provided the soil is dry; but if it is a very wet soil, it is better to defer it till the latter end of February, or the beginning of March; and for many kinds of evergreens, the beginning of April is by far the best season; though they may be safely removed at Midsummer, provided they are not to be carried very far; but you should always make choice of a cloudy wet season.

PLANTS, in Botany, organic vegetable bodies, consisting of roots and other parts.

Increase of Plants or Vegetables.—The seeds of many kinds of vegetables are so numerous, that if the whole produce of a single plant were put into earth, and to come to maturity in due course, the whole surface of the earth would be covered with them in a few years. Thus, the hyoscyamus, which of all known plants, produces the greatest number of seeds, would for this purpose require no more than four years. According to some experiments, it has been found, that one stem of the hyoscyamus produces more than 50,000 seeds, and if we admit the number to be only 10,000, it would amount, at the fourth crop, to 1,000,000,000,000,000; and as the whole surface of the earth is calculated to contain no more than 5,507,834,452, 170,250 square feet, it will be seen, that if we allow only a square foot to each plant, the whole surface of the earth would be insufficient to contain the produce of a single hyoscyamus at the end of the fourth year.

PLASTER, in Pharmacy, is defined to be an external application, of a harder consistence than our ointments; these are to be spread according to the different circumstances of the wound, place, or patient, either upon linen or leather.

PLASTER, among Builders, &c. The plaster of Paris is a preparation of several species of gypsums, dug near Mont Maitre, a village in the neighbourhood of Paris; whence the name.

PLAT, a sort of plaited cordage formed of the yarns of old rope twisted into foxes. It is used to wind about that part of the cable which lies in the hawse-hole, where it would otherwise be greatly injured by the continual friction produced by the agitation of the ship in stormy weather. See the articles **FRANKEN** and **HARVEY**.

PLATALKA, the *Spoonbill*, in Ornithology, a genus belonging to the order of grallæ. The beak is plain, and dilates towards the point into an orbicular form; the feet have three toes, and are half-palmated. There are three species.

PLATANUS, the *Plane Tree*, a genus of the polyandria order, in the monœcia class of plants. There are two species, the Oriental and American.

PLATBAND of a Door or Window, is used for the lintel, where that is made square, or not much arched; these platbands are usually crossed with bars of iron when they have a great

bearing, but it is much better to cover them by another of discharge built over them.

PLATE BALLISTAY, is a piece of iron used instead of a chain to connect the lower dead-eye of the backstay.

Foot-lead, or **Foot-plate**, are iron bands fitted to the lower dead-eyes of the top-mast shrouds, which pass through holes in the edge of the top, are attached to the upper ends of the foot-lead shrouds.

PLATFORM, is a number of planks laid together, forming a kind of floor for any temporary or particular purpose.

PLATFORM, in the Military art, an elevation of earth, on which cannons are placed, to fire on the enemy; such are the mounds in the middle of curtains. On the ramparts there is always a platform, where the cannons are mounted. It is made by the heaping up of earth on the rampart; or by an arrangement of madders rising insensibly, for the cannon to roll on, either in a casement or an attack on the outworks. All practitioners are agreed that no shot can be depended on, unless the piece can be placed on a solid platform; for if the platform shakes with the first impulse of the powder, the piece must likewise shake, which will alter its direction, and render the shot uncertain.

PLATFORM, or *Orlop*, in a ship of war, a place on the lower deck, abaft the main-mast, between it and the cockpit, and round about the main capstan, where provision is made for the wounded men in time of action.

PLATINA, is one of the metals, for the discovery of which we are indebted to our contemporaries. Its ore has recently been found to contain likewise four new metals,—palladium, iridium, osmium, and rhodium, (which see.) besides iron and chromium. Pure or refined platina is by much the heaviest body in nature. Its specific gravity is 21.54. It is very malleable, though considerably harder than either gold or silver; and it hardens much under the hammer. Its colour on the touchstone is not distinguishable from that of silver. Pure platina requires a very strong heat to melt it; but when urged by a white heat, its parts will adhere together by hammering. This property, which is distinguished by the name of welding, is peculiar to platina and iron, which resemble each other likewise in their infusibility. Platina is not altered by exposure to air, neither is it acted upon by the most concentrated simple acids, even when boiling or distilled from it. The aqua regia best adapted to the solution of platina, is composed of one part of the nitric, and three of muriatic acid. The solution does not take place with rapidity. From its hardness, infusibility, and difficulty of being acted upon by most agents, platina is of great value for making various chemical vessels. Platina may be drawn into very fine wire. There are two oxides of platina. It is dissolved in chlorine, and sulphate of platina may be obtained by passing a current of sulphuretted hydrogen gas through the nitro-muriatic solution. A fulminating powder is obtained from platina.

PLATING, is the art of covering baser metals with a thin plate of silver, either for use or for ornament. It is said to have been invented by a spur-maker, not for show, but for real utility. Till then the more elegant spurs in common use were made of solid silver; and from the flexibility of that metal, they were liable to be bent into inconvenient forms by the slightest accident. To remedy this defect, a workman at Birmingham contrived to make the branches of a pair of spurs hollow, and to fill that hollow with a slender rod of steel iron. Finding this a great improvement, and being desirous to add cheapness to utility, he continued to make the hollow larger, and of course the iron thicker and thicker, till at last he discovered the means of coating an iron spur with silver in such a manner as to make it equally elegant with those which were made wholly of that metal. The invention was quickly applied to other purposes; and to numberless utensils, which were formerly made of brass or iron, are now given the strength of these metals, and the elegance of silver, for a small additional expense.

PLATONIC YEAR, or the *Great Year*, is the period of time determined by the revolution of the equinoxes, upon a supposition of the precession going on uniformly till they have made one complete revolution. See **PRECESSION**.

PLATOON, in the Military art, a small square body of forty or fifty men, drawn out of a battalion of foot, and placed be-

Printing Presses.

between the squadrons of horse, to sustain them; or in ambuscades, straits, and defiles, where there is no room for whole battalions or regiments.

PLATYPUS, a quadruped of the order of bruta, but with a mouth shaped like the bill of a duck; feet webbed.

PLEA, that which either party alleges for himself in court. These are divided into pleas of the crown and common pleas. Pleas of the crown are all suits in the king's name against offences committed against his crown and dignity, or against his crown and peace. Common pleas are those that are held between common persons. Common pleas are either dilatory, or pleas to the action. Pleas dilatory, are such as tend merely to delay or put off the suit, by questioning the propriety of the remedy rather than by denying the injury. Pleas to the action, are such as dispute the very cause of suit. 3 Black. 301.

PLEADINGS, in general, signify the allegations of parties to suits, when they are put into a proper and legal form; and are distinguished in respect to the parties who plead them, by the name of bars, replications, rejoinders, sur-rejoinders, rebutters, sur-rebutters, &c. and though the matter in the declaration of court does not properly come under the name of pleading, yet, being often comprehended in the extended sense of the word, it is generally considered under this head.

PLEASURE BOAT, a boat fitted up for receiving company to sail up and down a river, harbour, or lake, &c.

PLEIADES, in Astronomy, an assemblage of stars in the neck of the constellation Taurus.

PLENE ADMINISTRAVIT, a plea pleaded by an executor or administrator, where they have administered the deceased's estate faithfully and justly before the action brought against them.

PLENUM, in Physics, denotes, according to the Cartesians, that state of things wherein every part of space is supposed to be full of matter; in opposition to a vacuum.

PLENUS FLOS, in Botany, a full flower; a term expressive of the highest degree of luxuriance in flowers. The petals in full flowers are so multiplied as to exclude all the stamina, and frequently to choke up the female organ, so that such flowers, though delightful to the eye, are vegetable monsters. Flowers with more than one petal are most liable to this; such as the ranunculus, anemomy, poppy, myrtle, &c. &c. Flowers with one petal only are but seldom subject to this fulness; these, however, are not totally exempt, as may be seen in the double polyanthus, hyacinth, crocus, &c. In flowers with one petal, the mode of luxuriance, or impletion, is by a multiplication of the divisions of the limb, or upper part. In flowers with more than one petal, is a multiplication of the petals or nectarium.

PLEURISY, in Medicine, a violent pain in the side, attended with an acute fever, a cough, and a difficulty of breathing.

PLEURONECTES, the *Flounder*, in Natural History, a genus of fishes of the order thoracici. Under this genus is included the *Hallibut*, the *Plaice*, the *Dab*, the *Flounder*, the *Sole*, the *Turbot*, &c. which require no particular description.

PLOT, in dramatic Poetry, is sometimes used for the fable of a tragedy or comedy, but more particularly the knot or intrigue which makes the embarrassment of any piece. The unravelling puts an end to the plot.

PLOT, in Surveying, the plot or draught of any field, farm, or manor, surveyed with an instrument, and laid down in the proper figure and dimensions.

PLOTTING, among Surveyors, is the art of laying down on paper, &c. the several angles and lines of a tract of ground surveyed by a theodolite, &c. and a chain.

PLOTUS, or **DARTER**, a genus of birds of the order anseres. The generic character is bill straight, pointed toothed; nostrils a slit near the base; face and chin naked; legs short, all the toes connected. Of this genus there are three species.

PLOUGH, in Agriculture, a machine for turning up the soil, contrived to save the time, labour, and expense, that without this instrument must have been employed in digging land to prepare it for the sowing of all kinds of grain.

Plough, among Bookbinders, is a machine for cutting the edges of the leaves of books smooth.

PLUG, a piece of timber formed like the frustum of a cone, and is used for different purposes, as. *Hawse-Plugs*, are made to stop the hawse holes when the cables are unbent,

or not in them. Their use is to prevent the water coming in when the ship pitches. *Shot Plugs*, are used to stop the breaches made in the bottom of a ship by cannon-balls, and are formed of various sizes, according to the different sizes of shot.

PLUMBERY, the art of casting and working lead, and using it in building.

PLUM-TREE. See **PRUNUS**.

PLUMMET, among Artificers, denotes a perpendicular to the horizon; so called as being commonly erected by means of a plummet.

PLUMMING, among Miners, is the method of using a mine-dial, in order to know the exact place of the work where to sink down an air-shaft, or to bring an adit to the work, or to know which way the load inclines when any flexure happens in it.

PLUNDER, in sea language, a name given to the effects of the officers and crew of a prize, when pillaged by the captors. In the military art, plunder is a booty of any kind.

PLUNGER, in Mechanics, the same with the forcer of a pump.

PLURALITY. If any person having one benefice with cure of souls of eight pounds a year in the king's books, shall accept another of whatsoever value, and be instituted and inducted into the same, the former benefice shall be void; unless he has a dispensation from the archbishop of Canterbury, who has power to grant dispensations to chaplains of noblemen and others, under proper qualifications, to hold two livings, provided they are not more than thirty miles distant from each other, and provided that he resides in each for a reasonable time every year, and that he keeps a sufficient curate in that in which he does not ordinarily reside.

PLUS in Algebra, a character marked thus +, used for the sign of addition.

PLUSH, in Commerce, a kind of stuff leaving a sort of velvet nap, or shag, on one side, composed regularly of a woof of a single woollen thread, and a double warp, the one wool, of two threads twisted, the other goat's or camel's hair; though there are some plushes entirely of worsted, and others composed wholly of hair.

PLUVIOMETER, a machine for measuring the quantity of rain that falls.

PLYING, in a nautical sense, is the act of making, or endeavouring to make, a progress against the direction of the wind, hence a *good Plyer* is a vessel that makes great advances in this manner of sailing.

PNEUMATICS, may be defined the science which treats of the properties of air in general, or perhaps with more propriety the term expresses the science that investigates the mechanical properties of elastic and æriform fluids, such as their weight, density, compressibility, and elasticity.

In the article **AIR PUMP**, page 21, I have shewn how the weight, or specific gravity, of the air may be ascertained. The density, compressibility, and elasticity of the air were illustrated in my explanation of the common air pump, its construction and principle of action, page 20 column 2.

I shall in this article confine myself to experiments in pneumatical science, as best calculated to illustrate its principles.

Preliminary Facts.—The air is a fluid which we breathe; for it envelops our globe to a considerable height around it. Clouds and vapours float in it, and the whole is called the *atmosphere*. As it is possessed of gravity, like other fluids, it must press upon bodies in proportion to the depth at which they are immersed in it; and it also presses in every direction, in common with all other fluids. It however differs from all other fluids in the four following particulars:—1. It can be compressed into less space than it naturally possesses. 2. It cannot be congealed or fixed as other fluids may. 3. It is of a different density in every part upward from the earth's surface, decreasing in its weight, bulk for bulk, the higher it rises; and therefore must also decrease in density. 4. It is of an elastic or springy nature, the force of its spring being equal to its weight.

People unacquainted with the principles of natural philosophy, would not suppose that the air by which we are surrounded, is a material substance, like other visible matter. Being invisible, and affording no resistance to the touch, it

seems to them extraordinary, to consider it as a solid and material substance, yet a few experiments will convince them that it is really matter, possessing weight, and the power of resisting bodies that press against it.

Experiment 1.—Take a bladder that has not the neck tied, you may press the sides together and squeeze it into any shape. Blow into this bladder, and tie a string fast round the neck; you cannot then, without breaking the bladder, press the sides together; you can scarcely alter its figure by pressure. Whence then arise these effects? When empty, you could press the bladder into any form; but the air with which it is filled prevents this; the resistance you experience, when it is filled with air, proves that air is matter.

Experiment 2.—We say a vessel is empty, when we have poured out of it the water it contained; but if a glass jar be plunged with its mouth downward into a vessel of water, there will but very little water get into the jar, because the air, of which it is full, keeps the water out. Or, throw a bit of cork into a basin of water, put an empty tumbler over it with the mouth downwards, force it down through the water; the cork will shew the surface of the water within the tumbler, and you will see that it will not rise so high within as without the glass; nor, if you press ever so hard, will it rise to the same level. The water is, therefore, prevented from rising within the tumbler, by some substance which occupies the inside. This substance is air.

Exp. 3. Open a pair of common bellows, stop up the nozzle securely: you cannot shut the bellows, which seems filled with something that yields a little, like wool; unstop the nozzle, the air will be expelled, it may be felt against the hand, and the bellows will now shut.—When the air is at rest we can move in it with facility; nor does it offer a perceptible resistance, except the motion be quick, or the surface opposed to it considerable; but when this is the case, its resistance is very perceptible, as may be easily perceived by the motion of a fan. When air is in motion, it constitutes wind, which is nothing more than a current or stream of air, varying in its force according to its velocity.

The invisibility of air, therefore, is only the consequence of its transparency; but it is possessed of all the common properties of matter. We say a vessel is empty, in the usual way of speaking, when it is filled with air.

The Mechanical Properties of Air.—But it is possible to empty a vessel of the air it contains, by which means we shall be able to discover several properties of this fluid. The instrument or machine by which this operation is performed, is called an *Air Pump*. See pages 20—23.

4. To demonstrate the weight of air by experiment, take a hollow copper ball, or other vessel, which holds a quart (wine measure), having a neck to screw on the plate of the air pump; weigh it when full of air, exhaust it, and weigh it when empty; it will have lost 16 grains, the weight of a quart of air. But a quart of water weighs 14624 grains: this divided by 16, quotes 914 in round numbers; so that water is 914 times as heavy as air, near the surface of the earth.

When the receiver is placed upon the plate of the air pump without exhausting it, it may be removed again with the utmost facility, because there is a mass of air under it that resists, by its elasticity, the pressure on the outside; but exhaust the receiver, thus removing the counter pressure, and it will be held down to the plate by the weight of the air upon it.

5. To determine what the pressure of the air amounts to. The surface of a fluid exposed to the air, is pressed by the weight of the atmosphere equally on every part, and remains at rest. If the pressure be removed from any particular part, the fluid yields in that part, and is forced out of its situation.

Into the receiver A put a small vessel with quicksilver, or any other fluid, and through the collar of leathers at B, suspend a glass tube, hermetically sealed, over the small vessel. Exhaust the receiver, let down the tube into the quicksilver, which will not rise into the tube as long as the receiver continues empty. Re-admit the air, the quicksilver will ascend. The reason is this: upon exhausting the receiver, the tube is likewise emptied of air; and therefore, when it is immersed in the quicksilver, and the air re-admitted into the receiver, the surface of the quicksilver is pressed upon by the air, except that portion

which lies above the orifice of the tube; consequently it must rise in the tube, and continue so to do, until the weight of the elevated quicksilver presses as forcibly on that portion which lies beneath the tube, as the weight of the air does on every other equal portion with the tube. Take a common syringe of any kind, and having pushed the piston to the farthest end, immerse it into water; draw up the piston, the water will follow, because, when the piston is pulled up, the air is drawn out of the syringe with it, and the pressure of the atmosphere is removed from the part of the water immediately under it; consequently the water is obliged to yield in that part to the pressure on the surface.

6. Upon this principle those pumps called *sucking pumps* act: the piston fitting tightly the inside of the barrel, by being raised up, removes the pressure of the atmosphere from that part, and consequently the water is drawn up by the pressure upon the surface. The pressure of the atmosphere is then the cause of the ascent of water in pumps; a column of water 34 feet high is a counterpoise to one as high as the atmosphere. As mercury is fourteen times as heavy as water, a column of that fluid need only be $\frac{1}{14}$ of the length of one of water, to form an equal counterpoise to the pressure of the air; and accordingly, having filled with mercury a glass tube about three feet long, hermetically sealed at one end, invert it into a small basin of mercury, and the mercury will rise to the height of about 29½ inches, and there remain suspended, leaving at the top of the tube a space or perfect vacuum; the column of mercury varies in height, and consequently the pressure of the air is different at different times. This phenomenon, too remarkable to be long unobserved, led to the observation that the changes in the height of the mercury were accompanied, or very quickly succeeded, by alterations in the weather. The instrument obtained the name of the weather glass: from its also measuring the weight of the atmosphere, it is called the *Barometer*, which is merely a tube filled with mercury, and inverted into a basin of the same. See *BAROMETER*, p. 91.

7. Take a receiver, open at the top, and cover it with your hand; exhaust the receiver, and thereby take off the pressure from the palm of the hand: you will then feel it pressed down by immense weight, so as to give pain that would soon be insupportable, and endanger the fracture of your hand.

8. If the top of the receiver be covered by a piece of flat glass, upon exhausting it, the glass will be broken to pieces by the incumbent weight; and this would happen to the receiver itself, but for its arched top, that resists the weight better than a flat surface. This experiment may be varied, by tying a piece of wet bladder over the open mouth of the receiver, and leaving it to dry until it becomes as tight as a drum. Upon exhausting the receiver, you will perceive the bladder rendered concave, and it will yield more and more, until it break with a loud report occasioned by the air striking forcibly against the inside of the receiver.

9. Air, one of the most elastic bodies in nature, is easily compressed into less compass than it commonly occupies; and when the pressure is removed, it regains its former bulk.

Let mercury be poured into a bent tube, A B C D, open at both ends, to a small height, as B C then stopping the end D with a cork or otherwise air-tight, measure the length of confined air D C, and pour mercury into the other leg A B, till the height above the surface of that in C D be equal to the height at which it stands in the barometer at the time. Then it is plain, that the air in the shorter leg will be compressed with a force twice as great as at first, when it possessed the whole space C D; for then it was compressed only with the weight of the atmosphere, but now it is compressed by that weight, and the additional equal weight of a column of mercury. The surface of the mercury will now be at E; and it will be found

upon measuring it, that the space D E, into which the air is now compressed, is just half the former C D. If another column of mercury were added, equal to the former, it would be seduced into one-third of the space it formerly occupied. Hence the density of the air is proportional to the force that compresses it.

As all the parts of the atmosphere gravitate, or press upon each other, the air next the surface of the earth is more compressed and denser than what is at some height above it, in the same manner as wool thrown into a pit. The wool at the bottom having all the weight of what was above it, would be squeezed into a less compass; the layer or stratum above it, would not be pressed so much; the one above that, still less; and so on, till the upper one, having no weight over it, would be in its natural state. This is the case with the air, or atmosphere that surrounds our earth, and accompanies it in its motion round the sun. On the top of lofty buildings, but still more on those of mountains, the air is less dense than at the level of the sea. The height of the atmosphere has never yet been exactly ascertained; on account of its elasticity, it may extend to an immense distance, becoming rarer in proportion to its distance from the earth. It is observed, that at a greater height than 45 miles, it does not refract the rays of light from the sun; and this is usually considered as the limit of the atmosphere. In a rarer state it may extend much farther, and this is by some thought to be the case, from the appearance of certain meteors which have been reckoned to be 70 or 80 miles distant, and whose light is thought to depend upon their coming through our atmosphere. A cubic inch of such air as we breathe, would be so much rarefied at the altitude of 500 miles, that it would fill a sphere equal in diameter to the orbit of Saturn.

10. There is a contrivance for supporting a guinea and a feather, and letting them drop at the same instant. If let fall while the receiver is full of air, the guinea will fall quicker than the feather; but if the receiver be exhausted, they both arrive at the bottom at the same instant, which proves that all bodies would fall to the ground with the same velocity, if it were not for the resistance of the air, which impedes most the motion of those that have the least momentum or weight. In this experiment, the observers ought to look at the bottom of the receiver, otherwise they will not be able to see whether the guinea and feather fall at the same instant.

11. Take a receiver, having a brass cap fitted to the top with a hole in it; fit one end of a dry hazel branch about an inch long, tight into the hole, and the other end tight into a hole quite through the bottom of a small wooden cup; pour quicksilver into the cup, exhaust the receiver, and the pressure of the outward air on the surface of the quicksilver will force it through the pores of the hazel, whence it will descend in a beautiful shower into a glass cup placed under the receiver to catch it.

12. Put a wire through the collar of leathers on the top of the receiver, and fix a bit of dry wood on the end of the wire within the receiver; exhaust the air, push the wire down so as to immerse the wood in a jar of quicksilver on the pump-plate; this done, let in the air, and upon taking the wood out of the jar and splitting it, its pores will be found full of quicksilver, which the force of the air drove into the wood.

13. Set a square phial upon the pump-plate, and having covered it with a wire cage, put a close receiver over it, exhaust the air out of the receiver; in doing which, the air will also make its way out of the phial, through a small valve in its neck—when the air is exhausted, turn the cock below the plate to readmit the air into the receiver: and as it cannot get into the phial again, because of the valve, the phial will be broken into pieces by the pressure of the air upon it. Had the phial been round, it would have sustained this pressure like an arch.

14. To shew the elasticity of air; tie up a very small quantity in a bladder, put it under the receiver; exhaust the air, the bladder (having nothing to act against it) will expand by the force of the air within it; upon letting the air into the receiver again, it will overpower that in the bladder, and press its sides close together.

If the bladder so tied be put into a wooden box, and have 20 or 30 pounds weight of lead placed upon it, and the box be covered with a close receiver; upon exhausting the air out of the

receiver, that confined in the bladder will expand and raise up the lead by the force of its spring.

15. If a rat, mouse, or bird, be put under a receiver, and the air be exhausted, the animal will be at first oppressed as with a great weight, then grow convulsed, and at last expire in agonies. This experiment is too shocking to be practised, and we therefore substitute a machine called the *lungs-glass*, in place of the animal.

If a butterfly be suspended in a receiver, by a fine thread tied to one of its horns, it will fly about in the receiver as long as it continues full of air; but if the air be exhausted, though the animal will not die, and will continue to flutter its wings, it cannot remove itself from the place where it hangs, in the middle of the receiver, until the air be let in again, and then the animal will fly about as before.

16. Put a cork into a square phial, and fix it in with wax or cement; and put the phial on the pump plate with the wire cage, and cover it with a close receiver; then exhaust the air out of the receiver, and the air that was corked up in the phial will break it outwards by the force of its spring, because there it no air left on the outside of the phial to act against that within it.

17. Put a shrivelled apple under a close receiver, exhaust the air, the spring of the air within the apple will plump it out, and cause the wrinkles to disappear: but upon letting the air into the receiver again, to press upon the apple, it will return to its former shrivelled state.

Take a fresh egg, cut off a little of the shell and film from its smaller end, put the egg under a receiver, and pump out the air; all the contents of the egg will be forced into the receiver, by the expansion of a small bubble of air contained in the greater end between the shell and the film.

18. Put some warm beer into a glass, set it on the pump, cover it with a close receiver, and then exhaust the air; the air therein will expand itself, and rise up in innumerable bubbles to the surface of the beer; and thence it will be taken away with the other air in the receiver. When the receiver is nearly exhausted, the air in the beer, which could not disentangle itself quick enough to get off with the rest, will now expand itself so as to cause the beer to have all the appearance of boiling; and the greatest part of it will go over the glass.

19. Put some water into a glass, and a bit of dry wainscot or other wood into the water; cover the glass with a close receiver, and exhaust the air; the air in the wood having liberty to expand itself, will come out plentifully, and make the water to bubble about the wood, especially about the ends, as the pores lie lengthwise. A cubic inch of dry wainscot has so much air in it, that it will continue bubbling for nearly half an hour together.

20. Let a piece of cork be suspended by a thread at one end of a balance, and counterpoised by a leaden weight, suspended in the same manner, at the other. Let this balance be hung to the inside of the top of a large receiver; set it on the pump, and exhaust the air, the cork will preponderate, and shew itself to be heavier than the lead; let in the air again, the equilibrium will be restored. The reason is, since the air is a fluid, and all bodies lose as much of their absolute weight in it as is equal to the weight of their bulk of the fluid, the cork being the larger body, loses more of its real weight than the lead; and therefore must be heavier, to balance it under the disadvantage of losing some of its weight. This disadvantage being taken off by removing the air, the bodies gravitate according to their real quantities of matter, and the cork which balanced the lead in air, shews itself to be heavier when in vacuo.

21. Set a lighted candle upon the pump, cover it with a tall receiver. If the receiver hold a gallon of air, the candle will burn a minute; and having gradually decayed from the first instant, it will go out; which shews that a constant supply of fresh air is as necessary to feed flame as to support animal life. The moment the candle goes out, the smoke will ascend to the top of the receiver, and form a cloud; upon exhausting the air, the smoke will fall down to the bottom of the receiver, and leave it clear at the top. This shews that smoke does not ascend on account of its being positively light, but because it is lighter than air; and its falling to the bottom when the air is taken away, shews that it is not destitute of weight. So most sorts

of wood ascend or swim in water; and yet there are none who doubt of the wood's having gravity or weight.

22. Set a receiver, open at top, on the air-pump, cover it with a brass plate and wet leather; having exhausted it of air, let the air in again at top through an iron pipe, making it pass through a charcoal flame at the end of the pipe; when the receiver is full of that air, lift up the cover, and let down a mouse or bird into the receiver; the burnt air will immediately kill it. If a candle be let down into that air, it will go out directly; but by letting it down gently, it will drive out the impure air and good air will get in.

23. Set a bell on the pump-plate, having a contrivance so as to ring it at pleasure, and cover it with a receiver; then make the clapper strike against the bell, and the sound will be very well heard; exhaust the receiver of air, if the clapper be made to strike ever so hard against the bell, it will make no sound: this shews that air is absolutely necessary for the propagation of sound.

Of condensed Air.—We now proceed to shew that the air can be condensed, or pressed into less space than what it generally occupies, by an instrument called a *condenser*; see page 23 for an engraving of the machine. It consists of a brass barrel containing a piston, which has a valve opening downwards: as the piston is raised, the air passes through the valve; as the piston is pushed down, the air cannot return, and is therefore forced through a valve at the bottom of the barrel, that allows it to pass into the receiver, but prevents it returning. At every stroke of the piston, more air is thrown into the receiver, which is of very thick and strong glass. The receiver is held down upon the plate by a bar, firmly screwed to two upright props, and the air is let out of the receiver by a cock. A great variety of experiments may be performed by means of condensed air. Thus the sound of a bell is much louder in condensed than in common air; and a phial that would bear the pressure of the common atmosphere, when the air is exhausted from the inside, will be broken by condensing the air around it.

The Air Gun.—This pneumatic instrument will drive a bullet with great violence by means of condensed air, forced into an iron ball by a condenser; but if the ball be not very good, it is apt to burst, and injure the operator. In 1820 a man was killed in Yorkshire by the bursting of the air-ball of an air gun. There are many contrivances used in constructing air-guns; some have a small barrel contained within a large one; and the space between the two barrels serves for the reception of condensed air. The magazine air-gun differs from the common one only by having a serpentine barrel which contains ten or twelve balls: these are brought into the shooting barrel successively, by means of a lever; and they may be discharged so fast as to be nearly of the same use as so many different guns: see AIR GUN, page 23.

POA, ANNUA. (Annual Meadow-Grass.) This, the most general plant in all nature, grows in every situation where there is vegetation. It has been spoken of as good in cultivation, and has had the term Suffolk grass applied to it, from its having grown in that county.

POA Aquatica, (Water Meadow-Grass.) is quite an aquatic, but is eaten when young by cattle, and is very useful in fenny countries: it is highly ornamental, and might be introduced into ponds for the same purpose as *Arundo phragmites*: it might also be planted with *Festuca elatior* and *Phalaris arundinacea*, in wet dug-out places, where it would be useful as fodder, and form excellent shelter for game.

Poa Fluitans, (Flote Fescue-Grass.) would be, of all others, the most nutritive and best plant for feeding cattle; but it thrives only in water. It is highly recommended by the editor of Curtis's Observations on British Grasses, 5th edition. Cattle are very fond of it; but it is not to be cultivated, except in ponds, being perfectly aquatic. Linnæus speaks of the seeds being collected, and sold in Poland and Germany as a dainty for culinary purposes; but it is never seen used here, neither are the seeds to be collected in great quantities. Stillingfleet speaks highly of its merits in a water meadow, and also quotes Ray's account of the famous meadow at Orchiston, near Salisbury. There this, as well as *Poa trivialis*, most certainly is in its highest perfection; but the real and general value of grasses, or other plants, must not be estimated by local instances.

POA Pratensis, (Smoothed-stalked Meadow-Grass.) is also a grass of considerable merit, when it suits the soil; it affects a dry situation, and in some such places it is the principal herbage.

POA Trivialis. (Rough-stalked Meadow-Grass.) Those who have observed this grass in our best watered meadows, and in other low pasture lands, have naturally been struck with its great produce and fine herbage. In some such places, it undoubtedly appears to have every good quality that a plant of this nature can possess; it is a principal grass in the famous Orchiston meadow, near Salisbury; but persons should not be altogether caught by such appearances; for it is in some lands, and such as would produce good red clover, a very diminutive and insignificant plant indeed. When persons wish to introduce it, they should carefully examine their neighbouring pastures, and see how it thrives in such places. The seeds are small, and six pounds would be sufficient for an acre, with others that affect a similar soil.

POCKET, in the woollen trade, a word used to denote a larger sort of bag, in which wool is packed up to be sent from one part of the kingdom to another. The pocket contains usually twenty-five hundred weight of wool.

POEM. See POETRY.

POETRY, is that kind of literary composition which is characterized by metrical harmony, and is by its very nature incapable of accurate definition. In the English language, versification depends on the modulation of the accents and the disposition of the pauses, to which is generally added the recurrence of rhyme. The heroic verse consists of ten syllables; its harmony is produced by a certain proportionate distribution of accented and unaccented syllables; and its specific character, whether lively or solemn, soft or slow, is determined by their order and arrangement. When unaccented and accented syllables are regularly alternated, it is called the iambic verse; as,

"A shep[herd's] boy, | he seeks | no high[er] name,
Led forth | his flock | beside | the sil[ver] Thame."

When this order is inverted, and the unaccented is preceded by the accented syllable, it is called a trochaic verse; as,

"Ambition first sprung from the blest abodes."

"Take, holy earth, all that my soul holds dear."

The heroic verse is often diversified by the intervention of an Alexandrine line of twelve syllables, which is liberally used by Dryden: its abuse is pointedly censured by Pope:

"A needless Alexandrine ends the song,
Which, like a wounded snake, drags its slow length along."

It forms a noble termination:

"Teach me to love and to forgive;
Exact my own defects to scan,
What others are to feel, and know myself a man."

The common anapestic verse, of eleven and twelve syllables, in which the accent falls on every third syllable, has generally been appropriated to humorous subjects: when formed into the stanza, it assumes a different character. In the noble war-song of Burns, it is however a strain truly sublime; and in the following passage flows with equal sweetness and pathos:

"Tis night, and the landscape is lovely no more:
I mourn, but, ye woodlands, I mourn not for you;
For morn is approaching, your charms to restore,
Perfum'd with fresh fragrance, and glittering with dew.
Nor yet for the ravage of winter I mourn;
Kind Nature the embryo blossom will save:
But when shall spring visit the mouldering urn?
Oh! when shall it dawn on the night of the grave?"

The occurrence of double rhymes is neither very frequent nor very easy in English verse; they are chiefly employed in songs, and are seldom admitted in the higher order of lyrical composition. The following passage from Dryden's Ode on St. Cecilia's Day, affords the most happy example of this kind of verse in our language:

"Softly sweet in Lydian measures,
Soon he sooth'd his soul to pleasures;
War, he sung, is toil and trouble,
Honour but an empty bubble;

Never ending, still beginning,
Fighting still, and still destroying:
If the world be worth thy winning,
Think, Oh! think it worth enjoying."

Blank verse is composed of lines of ten syllables each, which flow into each other without the intervention of rhymes; its metrical principles reside in its pauses, which should be so judiciously spread as never to suffer the accompaniment of rhyme to be missed. Attempts have been made to enlarge the limits of blank verse, by the introduction of various measures analogous to those employed in rhyme: but to all these efforts the genius of the language discovers an invincible repugnance; vainly are varieties presented to the eye, which are imperceptible to the mind, and untasted by the ear. All rhymeless numbers either flow into good blank verse, or form lines harsh and intractable; a succession of abrupt sounds and mutilated sentences, which by no art of typography, by no imposition of nomenclature, can be made to constitute any metre at all.

Poetical Classification.—Pastoral poetry is, above all other, the most limited in its object; and when formed on the model presented to us by Virgil and Theocritus, should be a description of rural scenes and natural feelings, enriched with elegant language, and adorned by the most melodious numbers. The ballad is perhaps the happiest vehicle of pastoral poetry, and there are in our language many ballads of exquisite beauty. The name of Elegy, originally given to funeral monody, was afterwards attached to all plaintive strains. In the Greek and Latin languages it was always written in alternate hexameter and pentameter verse. By the moderns an elegiac stanza was invented, assimilating as nearly as possible with those slow melodious numbers. Many elegies, and perhaps the best, are expressive only of soothing tenderness. Such are those of Tyrtæus and Alcæus, imitated by Tibullus among the Romans, and so happily by our countryman Hammond. The Jesse of Shenstone, which has perhaps never been surpassed, is all pathos. The celebrated elegy of Gray combines every charm of description and sentiment. The elegiac stanza, the monotony of which soon becomes oppressive to the ear, is sometimes happily exchanged for a lighter measure, as in Cowper's Juan Fernandez:

"Ye winds that have made me your sport,
Convey to this desolate shore
Some cordial endearing report
Of a land I shall visit no more.
My friends do they now and then send
A wish or a thought after me?
Oh! tell me I yet have a friend,
Though a friend I am never to see."

The Sonnet represents in an abridged form the ancient elegy, or the same slow stanza is assigned to each, and the sentiments suitable to the one are appropriate to the other. It is always limited to fourteen lines, an artificial character, which should seem to indicate an Oriental extraction. Lyric poetry is versatile and miscellaneous, admitting almost every diversity of measure and of subject. Love and heroism, friendship and devotional sentiment, the triumphs of beauty and the praises of patriotism, are all appropriate to lyrical composition. The soul of enthusiasm, the spirit of philosophy, the voice of sympathy, may all breathe in the same ode. Of our lyrical writers, Dryden is confessedly eminent; Gray is distinguished by the majesty and delicacy of his expression and the correctness of his style; Collins is occasionally animated by a portion of Pindaric spirit. But perhaps there has not appeared in our language a more chaste and pleasing lyric poet than the present professor Smyth, of Cambridge, whose English lyrics breathe throughout all the chaste and soothing strains of genuine poetic enthusiasm. Didactic poetry is minutely preceptive, and professes to convey useful instruction on some particular subject. It is obviously not easy to discover situations in which an author may become a practical teacher, without ceasing to be the poet: and this difficulty is aggravated to the English writer, who has not the resources of the Greek and Roman in the metrical capacities of his language. Satirical poetry is descriptive of men and manners; its aim is to delineate the follies and chastise the vices of the age. Satire is evidently the offspring of polished times; and, unlike other

poets, the satirist finds his empire enlarged, and his influence extended, by the progress of society. Satire is either pointed or oblique; eloquence is the soul of the one, ridicule of the other. The one rushes on its object in a torrent of vehemence and declamation; the other pursues a smooth tortuous course, occasionally reflecting to the mind the most momentous truths in the playful aspect of wit and humour. Epic poetry concentrates all that is sublime in action, description, or sentiment. In the structure of a regular epic poem, criticism requires that the fable should be founded in fact, and that fiction should fill the picture of which the outline is traced by truth. In the conduct of the poem, it is exacted that the machinery be subservient to the main design, and that the action should be simple and uniform. There are, however, many poems of the epic or heroic cast, to which criticism has hitherto assigned no name.

It is obvious that the poetical nomenclature established on classical authority, is not sufficiently extensive to include all the compositions of modern times. To what classical school shall we refer the noble ethics of Pope in his Epistles, and of Cowper in his Task? By what name shall we designate the Traveller and the Deserted Village, the Pleasures of Memory, the Pleasures of Hope, neither of which is like the Pleasures of Imagination included in the didactic species, with many other exquisite productions. Originally the drama was a metrical composition, and exhibited all the critical refinements of poetry. The title of poet is still given to every dramatic author, although he should have written in prose, and although the highest dramatic powers may exist without the smallest talent for poetry. The avowed object of the drama is to develop the passions, or to delineate the manners of mankind: tragedy effects the one, and comedy the other. In the English language are many popular dramas of a mixed character, which are written in verse intermingled with prose, and which are called plays. The English drama deviates essentially from that of classical antiquity; and independent of the division of acts and scenes, there is little resemblance between them.

The *curiosa felicitas*, that charm or felicity of expression which Horace so happily exemplified, is one of the most powerful agents in producing poetical emotion. It is the attribute which belongs only to the poet of nature; and is the effusion of some fortunate moments, when consummate judgment has been impelled and inspired by exquisite feeling. The spirit of poetry is not confined to subjects of dignity and importance; it may be perceived in a simple lay, and even in a sportive song. It visited Sappho, as it had sojourned with Pindar; and was as truly the attendant of Theocritus as of Homer. Nor is poetical emotion inspired only by the song of heroes and of gods; it may be awakened even by the strain of playful tenderness, in which the lover celebrates some darling of his mistress. See BLAIR'S *Lectures*, CAMPBELL'S *Philosophy of Rhetoric*, KAIMES'S *Elements of Criticism*.

POINT, in Geometry, as defined by Euclid, is a quantity which has no parts, or which is indivisible. Points are the ends or extremities of lines. If a point is supposed to be moved any way, it will, by its motion, describe a line.

POINT, is also an iron or steel instrument, used with some variety in several arts. Engravers, etchers, cutters in wood, &c. use points to trace their designs on the copper, wood, stone, &c.

POINT, in the Manufactories, is a general term used for all kinds of laces wrought with the needle; such are the point de Venise, point de France, point de Genoa, &c. which are distinguished by the particular economy and arrangement of their points.

POINT, among Sailors, a low arm of the shore which projects into the sea, or into a river, beyond the contiguous part of the beach. *To Point a Gun*, to direct it towards any particular object or point. *To Point a Sail*, to affix points through the eyelet holes of the reefs. See POINTS.

POINT Blank, in Gunnery, denotes the shot of a gun levelled horizontally.

POINTING, in Naval affairs, is the operation of tapering the end of a rope, and weaving some of its yarns into a kind of mat about the diminished part of it, so as to thrust it more easily through any hole, and prevent it from being untwisted. Thus the end of a reef-line is pointed so, that being stiffer, it

may more readily penetrate the eyelet holes of the reef; and the ends of the strands of a cable are occasionally pointed for the greater convenience of splicing it to another cable, especially when this task is frequently performed. The extremities of the splice of a cable are also pointed, that it may pass with more facility through the hawse-holes. In ships of war, it is customary to point the ends of almost all the ropes.

POINTS, in Naval affairs, flat pieces of braided cordage, tapering from the middle towards each end, whose lengths are nearly double the circumference of the yard, and used to reef the courses and top-sails of a square-rigged vessel; they are fixed to the sails by passing one through every eyelet hole in the reef-bands, and making two knots upon it, one on each side of the sail, to prevent its falling out. See REEF.

POINTS of the COMPASS, are the 32 principal points into which the horizon and compass-card are divided. See COMPASS.

POINTS, in Heraldry, are the several different parts of an escutcheon, denoting the local positions of any figure.

POISONS, substances which, when applied to living bodies, tend to derange the vital functions and produce death. Some poisons act by their corrosive property, as arsenic and corrosive sublimate; other poisons by being most powerfully astringent; some poisons are acrid, others narcotic and stupifying, which probably have a direct power upon the brain; some destroy animal life by their putrescent qualities.

POISONS, WITH THEIR SYMPTOMS AND ANTIDOTES.

Substances. Concentrated acids: the vitriolic, nitric, muriatic, oxalic, &c.—**Symptoms.** Burning pain, vomiting. Matter thrown up effervesces with chalk, or salt of tartar, or lime, or magnesia.—**Antidotes.** Calined magnesia: one ounce to a pint of warm or cold water. A glass full to be taken every two minutes, so as to excite vomiting. Soap, or chalk and water; mucilaginous drinks afterwards, such as linseed-tea, or gum arabic and water.

Substances. Alkalies: soda, ammonia, lime, &c.—**Symptoms.** Nearly the same as above: the ejected matter does not effervesce with alkalis, but with acids.—**Antidotes.** Vinegar and lemon juice: a spoonful or two in a glass of water very frequently; simply warm water.

Substances. Mercurial preparations: corrosive sublimate, &c. &c.—**Symptoms.** Sense of constriction in the throat: matter vomited sometimes mixed with blood.—**Antidotes.** White of eggs; twelve or fifteen eggs beat up and mixed with a quart of cold water. A glass full every three minutes. Milk, gum-water, linseed-tea.

Substances. Arsenical preparations: white arsenic, &c. &c.—**Symptoms.** Extreme irritation, pain, sickness, and speedy death, if the poison be not soon counteracted.—**Antidotes.** Warm water with sugar, in large quantities, to excite vomiting. Lime-water, soap and water, pearl-ash and water, mucilaginous drinks.

Substances. Preparations of copper, brass, &c. verdigris, halfpence, pins, &c. &c.—**Symptoms.** Nearly the same as from mercury.—**Antidotes.** White of eggs: (see under mercury,) mucilaginous drinks.

Substances. Preparations of antimony: emetic tartar, &c.—**Symptoms.** Extreme sickness, with other symptoms of poison, as above stated.—**Antidotes.** Warm water, or sugar and water; afterwards a grain of opium, or fifteen drops of laudanum every quarter of an hour, for two or three times.

Substance. Nitre.—**Symptoms.** Obstinate vomiting, sometimes of blood, &c. &c.—**Antidotes.** The same as for arsenic, with the exception of lime-water and alkalies.

Substance. Phosphorus.—**Symptoms.** Like mineral acid.—**Antidotes.** Same treatment as last mentioned.

Substances. Lead: sugar of lead, goulard extract, &c.—**Symptoms.** Great pain in the stomach, with constriction of the throat, &c. &c.—**Antidotes.** Large doses of Glauber's or Epsom salts, in warm water.

Substances. Opium, henbane, hemlock, nux vomica, deadly nightshade, berries, mushrooms, &c. &c.—**Symptoms.** Stupor, desire to vomit, heaviness in the head, dilated pupil of the eye, delirium, and speedy death.—**Antidotes.** Four or five grains of tartar emetic in a glass of water; if this does not succeed, four grains of blue vitriol, as an emetic. Do not give large

quantities of water. After the poison has been ejected, give vinegar, lemon juice, or cream of tartar. Strong coffee also is useful.

Substance. Poison of the yellow-billed sprat.—**Antidote.** Solution of sugar.

Opium and arsenic, it is well known, are poisons; and, as the effects of these are often fatal before medical aid can be procured, it may not be improper to state briefly the principal antidotes to either. When poison of any kind has been swallowed, the immediate object should always be that of endeavouring to excite vomiting; but much time is often lost by waiting the operations of medical emetics, when the discharge from the stomach might be much more speedily effected by mechanical means. Let, then, the persons who are about the individual who has taken poison, force a feather, or a piece of stick, or any thing that can be immediately procured, down the throat, and thus continue to irritate the parts till vomiting is induced. Emetics are of course to be administered as soon as they can be procured, when the power of swallowing is not suspended. After the contents of the stomach have thus been discharged, it is of consequence to recollect that acids are the best correctives of opium, and alkalies of arsenic. In the one case, that of opium, then, let vinegar or lemon juice, diluted with about an equal quantity of water, be freely and copiously administered: in the other, that of arsenic, let a solution of soap in water be made as strong, and poured down as quickly as possible. This last answers a double purpose, the alkali of the soap acting upon the acid of the arsenic, and thus destroying its virulence; and the oily principle of this material, liberated in some measure from its alkali, seems to lubricate the coat of the stomach, and thus at once to abate the inflammation already excited, and to defend the parts from the further influence of the poison. See SYRINGE.

POLACRE, in sea language, a ship with three masts, usually navigated in the Mediterranean; each of the masts are commonly formed of one piece, so that they have neither tops or cross-trees, neither have they any horses to their upper yards, because the men stand upon the top-sail yards to loose or furl the top-gallant-sails, and upon the lower yards to loose, reef, or furl the top-sails, the yards being lowered sufficiently down for that purpose.

POLAR, relating to the pole.

POLAR Circles. See CIRCLE.

POLE, in Astronomy, one of the extremities of the imaginary axis on which the sphere is supposed to revolve. These two points are each 90 degrees from the equator, that towards the north being called the north pole, and the other the south pole.

POLE, in Geography, one of the points on which the terraqueous globe turns, each of them being 90 degrees distant from the equator, and are denominated the north or south pole, according as they point towards the north or south points of the heavens. In consequence of the inclination of the terrestrial axis to the plane of the ecliptic, and its parallelism during its annual motion in its orbit, these parts of the world have only one day and one night throughout the year, each continuing for about six months.

It is singular that though the poles have a greater portion of light than any other parts of the globe, yet the name by which they are denoted in most languages, both ancient and modern, is derived from terms signifying darkness and obscurity; but though they really enjoy more light upon the whole than any other parts, yet in consequence of the obliquity with which the rays of the sun fall upon them, and the great length of winter night, the cold is so intense, that those parts of the globe that lie near the poles have never been fully explored, though the attempt has been repeatedly made by the most celebrated navigators.

Elevation of the POLE, is an angle subtended between the horizon of any place, and a line drawn from thence to the pole, which is always equal to the latitude of the place.

POLE, in Spherics, a point equally distant from every part of the circumference of a great circle of the sphere; or it is a point 90° distant from the plane of a circle, and in a line called the axis, passing perpendicularly through the centre. The zenith and nadir are the poles of the horizon; and the poles of the equator are the same with those of the sphere.

Machine for Illustrating the Effects of the Centrifugal Force in Flattening the Poles of the Earth.—The following figure represents this machine, which consists of two flexible circular hoops, A B and C D, crossing each other at right angles, and fixed to the vertical axis E F at its lower extremity, but left loose at the pole or intersection E. If this axis be made to revolve rapidly by means of the winch m, and the wheel and

pinion n, &c. the middle parts A, B, C, D, will, by their centrifugal force, swell out and strike against the frame; if the pole E, when sinking, is not stopped by means of a pin E fixed in the vertical axis. The hoops, therefore, have a spheroidal form; the equatorial being larger than the polar diameter.

Poles of the *Ecliptic*, are two points on the surface of the sphere, $23^{\circ} 30'$ distant from the poles of the world, and 90° distant from every part of the ecliptic.

POLES, in Magnetism, are two points of a loadstone corresponding to the poles of the world; the one pointing to the north, the other to the south. See **MAGNETISM**.

Pole, or *Polar Star*, is a star of the second magnitude, the last in the tail of *ursa minor*.

Pole, *Perch* or *Rod*, in Surveying, is a measure containing sixteen feet and a half.

POLE-AXE, a sort of hatchet, nearly resembling a battle-axe, having a handle about fifteen inches long, and being furnished with a sharp point, bending downwards from the back of its head. It is principally used on board of ships to cut away the rigging of an adversary who endeavours to board. They have also been sometimes employed in boarding an enemy whose hull was more lofty than that of the boarders, by driving the points into her side, one above another, and thereby forming a kind of scaling-ladder; whence they are sometimes called *boarding-axes*.

POLECAT, in Zoölogy, the name by which a creature of the weasel kind is known. It is sometimes also called *Fitchet*, and is remarkable for its stinking smell. This animal proves exceedingly destructive to rabbits when it finds a lodgment in warrens; many contrivances are therefore made for its destruction.

POLEMSCOPE, in Optics, a kind of reflecting perspective glass invented by Hevelius, who commends it as useful in sieges, &c. for discovering what the enemy is doing, while the spectator lies hid behind an obstacle.

POLES, *Under Bare*, the situation of a ship at sea, when all her sails are furled. See **SCUDDING** and **TRYING**.

POLICY of ASSURANCE, the deed or instrument by which a contract of assurance is effected.

POLISHER, or *Burnisher*, among Mechanics, an instrument for polishing and burnishing things proper to take a polish.

POLISHING, in general, the operation of giving a gloss or lustre to certain substances, as metal, glass, &c. The operation of polishing optic glasses, after being perfectly ground, is one of the most difficult points of the whole process. Before the polishing is begun, it is proper to stretch an even well-

wrought piece of linen over the tool, dusting upon it some very fine tripoli. Then taking the glass in your hand, run it round forty or fifty times upon the tool, to take off the roughness of the glass about the border of it. This cloth is then to be removed, and the glass to be polished upon the naked tool, with a compound powder made of four parts tripoli mixed with one of fine blue vitriol; six or eight grains of which mixture are sufficient for a glass five inches broad. This powder must be wetted with eight or ten drops of clear vinegar, in the middle of the tool; being first mixed and softened thoroughly, with a very fine small mullet. Then, with a nice brush, having spread this mixture thinly and equably upon the tool, take some very fine tripoli, and strew it thinly and equably upon the tool so prepared, after which, take the glass to be polished, wiped very clean, and apply it on the tool, and move it gently twice or thrice in a straight line backwards and forwards; then take it off, and observe whether the marks of the tripoli, sticking to the glass, are equably spread over the whole surface; if not, it is a sign that either the tool or glass is too warm, in which case you must wait a while and try again, till you find the glass takes the tripoli every where alike.

Sir Isaac Newton nowhere expressly describes his method of polishing optical glasses; but his method of polishing reflecting metals, he thus describes in his *Optics*. He had two round copper plates, each six inches in diameter, the one convex, the other concave, ground very true to one another. On the convex one he ground the object-metal, or concave, which was to be polished, till it had taken the figure of the convex, and was ready for a polish. He then pitched over the convex very thinly, by dropping melted pitch upon it, and warming it to keep the pitch soft, whilst he ground it with the concave copper wetted, to make it spread evenly all over the convex, till it was no thicker than a sixpence; and after the convex was cold he ground it again, to give it as true a figure as possible. He then ground it with very fine putty, till it made no noise; and then upon the pitch he ground the object-metal with a brisk motion, for two or three minutes; when laying fresh putty upon the pitch, he ground it again till it had done making a noise, and afterwards ground the object-metal upon the pitch as before; and this operation he repeated till the metal was perfectly polished. See **LENS** and **SPECULA**.

The Parisians have now introduced an entirely new mode of polishing, which is called *plaque*, and is to wood precisely what plating is to metal. The wood, by some process, is made to resemble marble, and has all the beauty of that article, with much of its solidity. It is even asserted by persons who have made trial of the new mode, that, with the exception of the actual strength of marble, it has no qualities superior to the imitation, upon which water may be spilled without staining, and it will resist scratching in the same degree as marble.

Method used in Germany for Varnishing Wood.—In the first place, the Germans are careful to join their wood very neatly, and to make the surface very smooth, because if the varnish brings out the beauty of the wood, it does the same by the defects. When the wood is once well polished, they prepare the varnish. For this purpose they reduce to a powder some of the purest shell lac, that is to say, very transparent, and dissolve it in well-rectified spirits of wine; they add, in a retort, double the quantity of alcohol to the lac employed, and expose it to a heat of about fifty degrees Reaumur. They are careful to agitate the mixture every three hours, until the varnish has acquired the suitable consistence; if it does not appear of a sufficient consistence, they add a little more pulverized lac; if on the contrary it is too thick, they mix a little more alcohol, being careful to agitate the mixture until it is of the right thick-ness. This varnish has no peculiar quality, except that it contains no turpentine, nor any other body that renders the varnish gloey, and liable to crack. They apply the varnish with a piece of fine linen, which is formed into a sort of pallet. The workman is previously provided with a mixture of two parts of varnish to one of olive oil, in which he soaks the linen, and then rubs it over the surface of the wood with great force, and pressing very hard upon it, but always in the direction of the fibres of the wood. He begins afresh by moistening the wood again, until the whole surface of the wood is covered with a slight coat of varnish. When the wood is well moistened with the

varnish, they leave it to dry, which it does very quickly, and they then apply a second coat, a third, and even a fourth if necessary. When the varnish is perfectly dry and hard, they give it the lustre in the following manner:—They steep a piece of fine linen in a mixture of olive oil and tripoli reduced to powder, and rub the wood hard with it until the varnish has acquired the proper degree of brilliancy. Then, to give it the last polish, they rub it with a piece of very soft linen, or very fine soft leather.

This varnish may also be applied with a brush, on bodies that do not offer an even surface, only it must then be made thinner, by adding a greater proportion of alcohol. It may afterwards be polished in the manner above described. When it is applied to bodies of great surface, it is essential that the varnish be made as thin as for bodies in relief, because as it dries quickly, the edges of the parts that are first laid on would acquire a degree of thickness which could not be reduced in the polishing. Lastly, articles that are turned in wood may be varnished and polished in the same manner even in the lathe. The only inconvenience attending this varnish is, that it gives the wood a brownish colour, which is no inconvenience where a deep colour is desired; and for which reason, it is much used in varnishing mahogany and the walnut and cherry tree woods. But when the wood is to be kept of a light colour, the varnish is made in the same manner, only, instead of the lac, they use copal gum dissolved in the alcohol, adding to it sometimes a little camphor or ether. This varnish may be applied with success to many different sorts of wood.

Some of the Vienna makers dissolve the copal by exposing it to the action of the vapour of alcohol, and sometimes they colour the copal varnish, which is naturally colourless, with any tint they may wish to give it; and they do not seem to use any spirits of turpentine to dissolve the copal. By this method of applying varnish to wood, it penetrates so completely into the grain, that it is almost impossible to crack it. So that when scraped, even with a sharp instrument, if the traces be not very deep, the polish may be restored by hard rubbing with a soft piece of linen. The gluey varnishes have not this advantage, since they do not penetrate so deep into the substance of the wood, and a scratch will take them almost clean off, in such a manner that no friction will restore the polish.

POLITICAL ARITHMETIC, calculations relating to the wealth of nations. Political arithmetic does not determine in what natural wealth truly consists, but estimates the value of whatever passes under this name, and distinguishes the proportions in which the component articles may be applied to purposes conducive to the safety or prosperity of the community.

POLITICAL ECONOMY, is the science which treats of the wealth of nations. Its object is to ascertain, in the first place, wherein wealth consists, and then to explain the causes of its production, and the principles on which it is distributed through the different orders of society. It likewise endeavours to point out the tendency which any political regulations may have to favour or to injure the productions, or most advantageous distribution of wealth. Such is its peculiar object; and consequently, though writers on political economy may frequently treat on the more important topics of national security, freedom, and happiness, they are then passing the strict limits of their science.

POLL, a word used in ancient writing for the head.

POLL Money, a capitation or tax, imposed by the authority of parliament on the head or person either of all indifferently, or according to some known mark of distinction.

POLLUX, in Astronomy, one of the Twins in the constellation Gemini; also a fixed star of the second magnitude in that constellation. See GEMINI.

POLYACUSTIC, any thing that multiplies sound.

POLYGAMY, the plurality of wives or husbands, in the possession of one man or woman at the same time.

POLYGLOTT, among divines and critics, chiefly denotes a bible printed in several languages.

POLYGON, in Fortification, denotes the figure of a town, or other fortress.

Line of POLYGONS, on the French sectors, is a line containing the homologous sides of the first nine regular polygons inscribed in the same circle; that is, from an equilateral triangle to a dodecagon.

POLYGON, in Geometry, a multilateral figure, or a figure whose perimeter consists of more than four sides, and consequently having more than four angles. If the angles be all equal among themselves, the polygon is said to be a regular one; otherwise it is irregular. Polygons also take particular names according to the number of their sides; thus a polygon of

- 3 sides is called a trigon,
- 4 sides is called a tetragon,
- 5 sides is called a pentagon,
- 6 sides is called a hexagon, &c.

and a circle may be considered as a polygon of an infinite number of small sides, or as the limits of the polygons. Polygons have various properties, as below:—

1. Every polygon may be divided into as many triangles as it has sides.

2. The angles of any polygon taken together, make twice as many right angles, wanting 4, as the figure hath sides; which property, as well as the former, belongs to both regular and irregular polygons.

3. Every regular polygon may be either inscribed in a circle, or described about it; which is not necessarily the case if the polygons be irregular. But an equilateral figure inscribed in a circle is always equiangular; though an equiangular figure inscribed in a circle is not always equilateral, but only when the number of sides is odd. For if the sides be of an even number, then they may either be all equal, or else half of them may be equal and the other half equal to each other, but different from the former half, the equals being placed alternately.

4. Every polygon, circumscribed about a circle, is equal to a right-angled triangle, of which one leg is the radius of the circle, and the other the perimeter or sum of all the sides of the polygon. Or the polygon is equal to half the rectangle under its perimeter and the radius of its inscribed circle, or the perpendicular from its centre upon one side of the polygon.

Hence the area of a circle being less than that of its circumscribing polygon, and greater than that of its inscribed polygon, the circle is the limit of the inscribed and circumscribed polygons: in like manner, the circumference of the circle is the limit between the perimeters of the said polygons. See CIRCLE.

5. The following table exhibits the angles and areas of all the polygons, up to the dodecagon, viz. the angle at the centre, the angle of the polygon, and the area of the polygon when each side is 1.

No. of Sides.	Name of Polygon.	Ang. F. at Cent.	Ang. C. of Polygon.	Area.
3	Trigon.....	120°	60°	0.4330127
4	Tetragon,	90	90	1.0000000
5	Pentagon,	72	108	1.7204774
6	Hexagon,	60	120	2.5980762
7	Heptagon,	51½	128½	3.6397194
8	Octagon,	45	135	4.6284271
9	Nonagon,	40	140	6.1818342
10	Decagon,	36	144	7.6942088
11	Undecagon,	32½	147½	9.3655380
12	Dodecagon,	30	150	11.1961534

Therefore to find the area of any regular polygon not exceeding 12 sides, square the side, and multiply that square by the corresponding tabular number in the preceding table. Or generally, if s represent the length of one of the equal sides, and n the number of them; then $s^2 \times \frac{n}{4} \times \tan\left(\frac{90n - 180}{n}\right) = \text{area of the polygon.}$

To inscribe a Polygon within, or to circumscribe a Polygon about a given Circle.—Bisect two of the angles of the given polygon A and B by the right lines AO, BO; and from the point O, where they meet, with the radius AO, describe a circle which will circumscribe the polygon. Next, to circumscribe a polygon divide 360 by the number of sides required to find the angle

A O B; which set off from the centre O, and draw the line A B, on which construct the polygon as in the following problem.
 2. On a given line to describe any given regular polygon. Find the angle of the polygon in the table, and at A set off an angle equal thereto; then drawing CA = AB, through the points C A B, describe a circle, and in this applying the given right line as often as you can, the polygon will be described.

Otherwise. To inscribe a Polygon in a Circle.—Draw the diameter A B, which divide into as many equal parts as the figure has sides. From the points A, B, as centres with the radius A B, describe arcs crossing each other in C. From the point C, through the second division of the diameters, draw the line C D. Join the points A, D, and the line A D will be the side of the polygon required.

Note.—In this construction A D is the side of a pentagon.

Another method, something more accurate, is by erecting a perpendicular from the centre of such a length that the part without the circle shall be equal to $\frac{1}{4}$ of that within, and drawing a line from its extremity through the second division as before.

In the preceding part of the article it is observed, that any regular polygon may be inscribed in, or circumscribed about, a circle: but this must be understood under certain modifications; all that is meant is, that there is nothing in the nature of the problem to render it impossible; and not that any polygon may be geometrically inscribed. In fact, the number of polygons that admit of a geometrical construction is very limited, viz. the equilateral triangle, the square and pentagon, and those figures whose number of sides are some multiples of these: to which Gauss has lately added the 17-sided polygon, and its multiples, and some others, viz. all those polygons whose number of sides is a prime, and of the form $2^n + 1$.

POLYGONAL Numbers, are those that are formed of the sums of different and independent arithmetical series, and are termed *Natural, Triangular, Quadrangular, Pentagonal, Hexagonal, &c. Numbers*; according to the series from which they generated.

Lineal, or Natural Numbers, are formed from the successive sums of a series of units; thus,

Units 1, 1, 1, 1, 1, 1, &c.

Nat. num. 1, 2, 3, 4, 5, 6, &c.

Triangular Numbers, are the successive sums of an arithmetical series, beginning with unity, the common difference of which is 1; thus,

Arith. series 1, 2, 3, 4, 5, 6, 7, &c.

Triang. num. 1, 3, 6, 10, 15, 21, 28, &c.

Quadrangular, or Square Numbers, are the successive sums of an arithmetical progression, beginning with unity, the common difference of which is 2; thus,

Arith. series 1, 3, 5, 7, 9, 11, 13, &c.

Quad. or squa. 1, 4, 9, 16, 25, 36, 49, &c.

Pentagonal Numbers, are the sums of an arithmetical series, the common difference of which is 3; thus,

Arith. series 1, 4, 7, 10, 13, 16, 19, &c.

Pentagonals 1, 5, 12, 22, 35, 51, 70, &c.

And, universally, the *mgonal Series of Numbers*, is formed from the successive sums of an arithmetical progression, beginning with unity, the common difference of which is $m - 2$.

POLYGONOMETRY, is an extension of the science of trigonometry, having the same reference to polygons in general, as trigonometry has to triangles in particular. We owe this extension of the rules of trigonometry to L'Huillier, who published a treatise on this subject at Geneva, in 1789; which, with the exception of a chapter in the third volume of Dr. Hutton's "Course of Mathematics," is, we believe, the only work on polygonometry at present before the public.

POLYGONUM BISTORTA. (*Bistort.*) *The Roots.* All the parts of the bistort have a rough austere taste, particularly the root, which is one of the strongest of the vegetable astringents. It is employed in all kinds of immoderate hæmorrhages and other fluxes, both internally and externally, where astringency is the only intention. It is certainly a very powerful styptic,

and is to be looked on simply as such; the sudorific, antipestiferous, and other like virtues attributed to it, it has no other claim to, than in consequence of this property, and of the antiseptic power which it has in common with other vegetable styptics. The largest dose of the root in powder is one dram.

POLYGONUM Fagopyrum. (*Buck Wheat.*) This is usually sown in places where pheasants are bred, as the seed is the best food for those birds; it is also useful for poultry and hogs. We have eaten bread and cakes made of the flower, which are also very palatable. Two bushels are usually sown per acre. The season is May; and it is often sown on foul land in the summer, as it grows very thick on the land, and helps to clean it by smothering all the weeds. The crop does not stand on the ground more than ten or twelve weeks.

POLYGRAM, a figure consisting of many lines.

POLYHEDRON, or POLYEDRON, a body or solid contained by many rectilinear planes or sides. When the sides of the polyhedron are regular polygons, all similar and equal, then the polyhedron becomes a regular body, and may be inscribed in a sphere; that is, a sphere may be described about it, so that its surface shall touch all the angles or corners of the solid. There are but five of these regular bodies, viz. the *tetrahedron*, the *hexahedron* or cube, the *octahedron*, the *dodecahedron*, and the *icosahedron*.

POLYHEDRON, Gnomonical, is a stone with several faces, on which are projected various kinds of dials. Of this sort, that in the Privy Garden, London, now gone to ruin, was esteemed the finest in the world.

POLYNEMUS, the *Polyneme*, in Natural History, a genus of fishes of the order abdominales. Shaw enumerates ten species; Gmelin only four. The Paradise polyneme, or mango fish, inhabits the Indian and American seas, and is thirteen inches long, elegantly shaped, and with thoracic filaments frequently far larger than the body; its colour is yellow. At Calcutta it is in the highest estimation for the table. The gray polyneme abounds on the Malabar coast, and has five filaments on each side, but all rather short. It is sometimes four feet long, and is in some parts of India denominated the royal fish, from its extraordinary excellence. The polyneme of the Nile is, both in form and taste, superior to every other fish in the rivers which flow into the Mediterranean or Atlantic seas. It is covered with scales resembling the most brilliant silver spangles, and is of the weight of thirty, in some instances of seventy pounds. It is a native of the Nile, and Bruce has minutely detailed the process adopted by the Egyptians for taking it, by a cake of flour, dates, and other ingredients, with a considerable number of hooks concealed in it; but attached to a string held by the fisherman, who floats on the stream upon a blown-up goat's skin, in order to sink this mass, and then returns to the bank. He then fixes the line to some tree, connecting it with a bell, the sounds of which give him notice of the success of his experiment, being produced by the twitchings and pulls of the fish.

POLYNOMIAL, in Algebra, a quantity consisting of many terms.

POLYPUS, the popular name for those fresh water insects which class under the genus of hydra, of the order of vermes zoophytæ.

POLYSCOPE, or POLYHEDRON, in Optics, a multiplying-glass, or one which represents a single object to the eye, as if there were many. It consists of several plane surfaces, disposed under a convex form, through each of which the object is seen.

POMELION, a name given by seamen to the cascabel, or hindmost knob of a cannon.

PONCHES, small bulk heads made in the hold to stow corn, goods, &c.

PONDERABILITY, a contingent property of bodies. Every substance within the sphere of observation is found to possess weight, or a disposition to gravitate towards the centre of the earth. But to constitute gravity, it is not required that a body should invariably fall to the ground. Smoke ascends in the atmosphere, and a lump of lead rises in a tub of mercury, from the same cause that a pine tree plunged into a lake mounts again to the surface. Withdraw the air, the mercury, and the water, which supported those comparatively lighter

substances, and the smoke, the lead, and the timber, will immediately descend. Pour mercury over a smooth piece of cork, applied to the bottom of a glass, and it will remain in the same situation, while an iron ball can be set to float on the liquid metal. The order of nature might here seem to be reversed. But, since mercury does not insinuate itself through a very narrow interstice, it merely rests on the upper side, without pressing against the under side, of the cork. If *levity*, however, as the schoolmen asserted, had been a real property belonging to certain bodies, the smoke and the cork would, in every instance, have occupied the lower stations. But the weight of a body is not the same in all places and situations. A lump of lead, which weighs a thousand pounds at the surface of our globe, would lose two pounds, as indicated by a spiral spring, if carried to the top of a mountain four miles high; and, if it could be conveyed as deep into the bowels of the earth, it would lose one pound. The same mass transported from London to the Pole, would gain the addition of 2 lbs. 769 decim. parts, (nearly 3 lbs.); but if taken to the Equator, it would suffer a loss of 4½ lbs. The variable, and therefore contingent, weight of bodies, is only the gradation of that mutual and universal tendency, diminishing as the square of the distance, which retains the moon in her orbit, and upholds the circulation of the whole system of planets around the sun. The gravitation even of small masses towards each other, such as balls of lead separated only by the interval of a few inches, has been detected by delicate experiment, and reduced to rigorous calculation. But when the approximation is closer, this force acquires a modified character, and passes into cohesion. Thus, if two leaden bullets have a little portion of the surface of each pared clean, and be then pressed together with a slight twist, they will cohere firmly into one mass. In the same manner, gold or silver foliage, and other ornaments, struck with a heavy hammer into the surface of polished iron or steel, become permanently united. Within other limits, the tendency to mutual approach is changed into an opposite quality. Thus, drops of rain or dew, run along the smooth and glossy surface of a cabbage leaf without spreading. If the dust of the lycopodium, or club fern, or even fine pounded rosin, be strewed on water contained in a glass, any smooth rounded piece of soft wood will float upon it, or may be immersed in the liquid, without being wetted, the powder preventing, by its repulsion, all contact of the water. A fine needle, laid on the surface of water, makes a dimple in which it swims. On the same principle, the slender limbs of insects, and the minute down which covers their wings, protects them from the penetration of humidity. If the hand be rubbed with linseed oil, it may be plunged with impunity for a few seconds in boiling water, the oil repelling the water, and consequently checking the communication of heat. The application of palm soap to the skin is still more effectual.

It thus appears that bodies are indefinitely porous, compressible without limits, and capable of assuming all variety of forms. How different is the constitution of ice, of water, and of steam? Consider what mutable aspects mercury exhibits. Beginning at a low degree of cold, and ascending through the gradations of heat, we find it a friable solid, next a shining liquid, then a penetrating vapour, and lastly, a fine red powder. A bright ductile piece of metal passes successively into an earthy oxide and pellucid glass. Charcoal is precisely of the same nature as the diamond; yet what a contrast between the dingy appearance of the one, and the dazzling lustre of the other? How variously are substances transformed by the operations of art? The skins of animals become changed into parchment and different kinds of leather, and its shreds into glue. The animal fibres are converted into matting, cordage, and linen cloth; and the rags, again, reduced to a pulp, and manufactured into paper.

How diversified appear the compounds of the farinaceous substances? By a distinct operation, the same grain produces gruel, bread, biscuit, starch, and a hard pellucid concretion resembling mother-of-pearl. But the plastic powers displayed in the process of vegetation and animal life, infinitely surpass the resources of art. Many plants are fed by water and air alone, and consequently these fluids are capable of being transformed into all the various products. In short, nature ex-

hibits only a chain of endless metamorphoses: the substance or material remains unchanged, but its form undergoes continual mutations.

The properties of bodies result from those of their component particles. At certain mutual distances they remain quiescent; but, at other distances, they show a disposition either to approach or to recede. Such opposite tendencies are commonly referred to the principles of attraction and repulsion. But all those diversified effects may be comprehended under a general law, which connects the mutual action of particles with their distance. In the language of modern analysis, the corpuscular energy is always some *function* of the distance; and it may be represented by an extended curve, of which the abscissæ mark the distances, and their ordinates express the corresponding forces. Fig. 1, exhibits this curve of primordial action; in which A denotes an action or ultimate particle, and B, C, D, E, &c. the successive positions of another particle, the perpendicular

Y CM, EN, GO, IP, LQ, &c. representing their mutual action attractive between B and D, F and H, K and X, when above the axis AX, and repulsive between D and F, H and K, below it. The final branch of the curve must gradually assimilate itself to the law of universal gravitation. But the primary branch of the curve must, in like manner, continually approach AY, the perpendicular to the axis; and since no pressure or impulsion can ever accomplish the penetration of matter, it follows, from the principles of Dynamics, that the space included between the curve and that asymptote must be finite. Where the curve repeatedly crosses the axis, are so many quiescent positions, B, D, F, H, K, &c. in any one of which a particle would continue in *equilibrium*. But this equilibrium is of two kinds, the *stable* or the *unstable*; the former easily recovering itself from any slight displacement, and the latter, when once disturbed, being irremediably dissolved. If the curve in its progress cross the axis from the side of repulsion to that of attraction, its intersection will evidently be a point of stability; for if a particle be pushed inwards, it will then be repelled back again; and if it be pulled outwards, it will experience an attractive force, which will recall it to its first position. But if the curve pass from attraction to repulsion, its intersection with the axis is a point of *unstable equilibrium*; for, in proportion as a particle is pressed inwards, it will be pulled forcibly from its position; and if it be drawn outwards, the repulsion, now conspiring, will bear it along with accumulating power. Thus, B, F, and K, the transitions from repulsion to attraction, are points of stability; but D and H, the opposite transitions, are points of instability.

According as the ordinates, near the points of transition, increase less or more rapidly, the tendency of the particles to coalesce, or to separate, will be proportionally feeble or intense. If the curve cut the axis very obliquely, therefore, it will mark a limit of languid cohesion, as at the point F; but if it shoot nearly at right angles across the axis, as at B or K, it will indicate a limit of powerful cohesion. Those atoms, or ultimate particles, have no sensible magnitude. But though the range of our conceptions may be in-

bounded, every thing in the material world appears to be distinct and determinate. Experience indeed informs us, to what astonishing degree matter can be attenuated, but philosophy describes the existence of certain fixed or impassable limits, at which the capability of farther subdivision utterly ceases. The primordial line of action is hence a physical, and not a mathematical curve; or it is not strictly incurvated at every point, but proceeds by successive minute deflections, corresponding to the breadth of the elementary particles. Such a modification of the curve is represented by fig. 2; being a serrated line, whose gradations answer to the successive stages of corpuscular action. Continuous shades, indeed, exist only in our modes of conception, and nature exhibits always individual objects, and advances by finite steps. The material world is hence reducible to atoms, actuated by forces depending merely on their mutual distances. From such simple elements,—the different arrangements of the particles,—and their multiplied interior combinations, this sublime scene of the universe derives all its magnificence and splendour.

PONTON, or **PONTOON**, in War, denotes a little floating bridge made of boats and planks. The ponton is a machine consisting of two vessels at a little distance, joined by beams, with planks laid across for the passage of the cavalry, the cannon, infantry, &c. over a river, or an arm of the sea, &c. See **BRIDGE**.

PONTOON, in Naval affairs, a large low flat vessel, nearly resembling a barge of burden, and furnished with cranes, capstans, tackles, and other machinery necessary for careening ships; these are principally used in the Mediterranean, but very seldom in the northern parts of England.

PONTOON, or *Ponton*, a kind of flat-bottomed boat, whose carcase of wood is lined within and without with tin. They are generally twenty-one feet long, five feet broad, and two feet one inch and a half deep within.

POOP, the highest and aftmost deck of a ship. *To have the Wind in Poop*, is to have it behind or favourable.

Poor Royal, a short deck, or platform, placed over the aftmost part of the poop in the largest of the French and Spanish men of war, and serving as a cabin for their masters and pilots. This is usually called the top-gallant-poop by our shipwrights.

POOPING, the shock of a high and heavy sea upon the stern or quarter of a ship, when she scuds before the wind in a tempest. This circumstance is extremely dangerous to the vessel, which is thereby exposed to the risk of having her whole stern beat in, by which she would be laid open to the entrance of the sea, and most probably founder.

POOPING, implies also the action of one ship running her stem against another's stern.

POOR LAWS. Of the general outline of this most enormous, and almost ineffectual burden on the people, much has been said in the excellent treatise of Mr. Colquhoun. The 43 of Eliz. c. 2, is the foundation of all that is good in the poor-laws; making provision for finding work for the industrious and able; for compelling the idle and able to labour; and for affording relief to the diseased and impotent; and the 13, 14, Charles II. c. 12, is the foundation of all that is evil, by forming the system of settlements and removals; a system establishing oppression, litigation, and expense, and which has been made more oppressive, and more productive of litigation and expense, by every subsequent statute, till the statute of the 35th of his late Majesty; which, by forbidding removals in case the paupers is not absolutely chargeable, has remedied more than half the evils occasioned by the former laws.

Overseers.—The churchwardens of every parish, with two, or three, or four substantial householders, according to the size of the parish, to be nominated in Easter week, or within a month after, under the hands or seals of two or more neighbouring justices, and who shall be called overseers of the poor. 43 Eliz. c. 2, s. 1. Where there are no churchwardens, the whole power is vested in the overseers. 17 Geo. II. c. 38, s. 15. Overseer dying or becoming incapable of acting, two justices may appoint another. *Ibid.* s. 3. If any person shall find himself aggrieved by any act of the justices, appeal to the sessions whose determination shall be final. *Ibid.* s. 6. Where there is no nomination of overseers, penalty 5*l.* on every justice of the division. Recovery by distress from the sessions, to be levied

by the churchwardens and overseers. 43 Elizabeth, c. 2, s. 10. Parish officers with the consent of two justices shall set children to work, whose parents cannot maintain them, and all persons married or single who cannot maintain themselves, and have no regular trade or calling; and one justice may send persons to the house of correction who will not work; and the parish officers, not having an excuse, to be allowed by two justices, shall meet once in a month at least, in the church, on a Sunday after evening service, to consult. Penalty 20*s.* Recovery by distress, and, in default, commitment till paid.—Application to two justices by the poor for an appeal to the sessions. *Ibid.* s. 1, 2, 6, 11.—Overseers, within four days of the end of their year, shall account to two justices of all sums received and paid, and pay over what remains to their successors; who in default may levy it by distress, under warrant of two justices; who, in default of distress, may commit till paid. *Ibid.* s. 2, 4.—Every parish officer neglecting to obey the regulations of the above act, penalty from 40*s.* to 5*l.* Recovery by distress. Application to two justices by the poor. 17 George II. c. 38, s. 14.—Parish officer neglecting his duty, or disobeying the warrant of a justice, penalty 40*s.* to be recovered by distress, and, in default, commitment not exceeding ten days, before two justices of the poor for an appeal to the sessions, giving ten days notice. 33 George III. c. 55, s. 1, 2.

Rate.—Parish officers shall raise by a rate on all the inhabitants, a stock of flax, &c. to set the poor to work, and sums for the relief of the old and lame who are not able to work, and for apprenticing poor children. Rate to be made by consent of two justices. 43 Elizabeth c. 2, s. 1.—Parish officers shall cause notice to be given publicly in the church, of such consent of the justices, the next Sunday; and no rate shall be collected till such notice is given. 17 George II. c. 3, s. 1. They shall permit the inhabitants to inspect such rates at all reasonable hours, on payment of 1*s.*; and give copies, on payment of 6*d.* for every twenty-four names. Penalty 20*s.* Application to the party aggrieved. *Ibid.* s. 2, 3.—Persons aggrieved by assessment appeal to the sessions. 17 George II. c. 38, s. 4. Goods of persons refusing to pay may be distrained in any part of the county; and of any other county, on oath made before a justice of such other county, which oath shall be certified in the warrant. Appeal to the sessions of the county where the assessment was made. *Ibid.* s. 7. If two justices perceive that the inhabitants of any parish are not able to levy money sufficient for the relief of the poor, they shall assess any neighbouring parishes within the hundred, in aid; and if the hundred be not of sufficient ability, then any parishes within the county, 43 Elizabeth, c. 2, s. 3. Father, grandfather, mother, or grand mother, of persons wanting relief, shall maintain them; penalty 20*s.* per month. Recovered by distress, and in default commitment till paid. Application to two justices by the poor. *Ibid.* s. 2, 11. Fathers leaving their wives and children, and mothers their children chargeable to the parish, having ability to maintain them, the parish officers, where such are left, may, by warrant of two justices, seize so much of the goods and chattels, or receive so much of the annual rent as such justices shall appoint, to reimburse the parish; and such order to be confirmed by the sessions. 5 George I. c. 8, s. 1. Parish officers, with consent of the lord of the manor, may, by order of two justices, erect cottages on waste lands, for the poor. 43 Elizabeth, c. 2, s. 5. They may also, with consent of two justices, set up trades, &c. for the employment of the poor. 3 Charles II. c. 4, s. 22.

Relief.—Parish officers, with consent of the majority of the inhabitants, may contract with any person for the lodging, keeping, maintaining, and employing the poor; and persons refusing such relief are not entitled to any other. 9 George I. c. 7, s. 4. The abominable oppression of this execrable law has, however, been removed by another humane statute of the late reign; for by 36 George III. c. 25, s. 1, 2, 3, it is enacted, that it shall be lawful for the parish officers, with the approbation of one justice, in writing, to relieve any industrious person at his own habitation, under certain circumstances of temporary illness, or distress; and one justice may order such relief for any time not exceeding one month, provided the cause be written on the back of the order, which the parish officers are bound to obey; and two justices may continue such orders from time to time, each period in succession not being more than

one month. A justice or a medical man, or clergyman by warrant of a justice, may visit workhouses, and examine the state of them, and hear complaints, and certify to the sessions; and if there should be any infectious disorder, the visiting justice shall apply to another justice, or any other person visiting, to two justices; which two justices shall order such regulations as they deem necessary till the next sessions. 30 George III. c. 49, s. 1, 2. Names of persons receiving parish relief to be entered in a book. 3 William, c. 11, s. 11. And no other person to be relieved but by order of a justice. *Ibid.* No relief to be ordered by a justice unless for a reasonable cause, proved on oath, and unless the pauper shall have first applied to a parish officer or a vestry, nor before the justice shall have summoned the parish officers. 9 George I. 6, 7, s. 1. The name of such persons to be entered with the others; and no parish officer, except on sudden emergency, shall bring any charge on the parish for persons not registered. Penalty 5*l.* Recovered by distress. Application to two justices by the poor. *Ibid.* s. 2.

Settlements.—The general heads on which settlements are founded are birth, apprenticeship, service, serving offices, renting 10*l.* per annum, marriage, and estate. A house at not less than 10*l.* per annum, for at least one whole year, for which term rent and taxes must be paid and occupied.

1. **Birth.**—Children *prima facie*, whether bastards or legitimate, are settled where born; but with respect to bastards, if a woman goes collusively to be delivered in another parish, the child gains no settlement there. Bastards born during an order of removal, or the suspension of it, belong to the mother's parish. 35 George III. c. 101, s. 6. And so of bastards born in vagrancy. 17 George II. c. 5, s. 25. And so if born in houses of industry in incorporated districts. 20 George III. c. 36. Or in friendly societies. 33 George III. c. 54, s. 25. Or in lying-in hospitals. 13 George III. c. 82. Legitimate children are settled as their parents, till old enough to gain a settlement of their own, the earliest period of which is seven years: at which age, by 6 Elizabeth, c. 6, s. 12, a child may be apprenticed to a person using the seas; and by 17 George II. c. 5, justices may bind the child of a vagrant of the same age; and any apprentice gains a settlement in a place where he has resided as such for forty days.

2. **Apprenticeship.**—The time required to gain a settlement has just been mentioned. The apprentice must be legally bound, except that the contract not being indented, which is fatal in every other case, is not in this. 31 George II. c. 11.

3. **Service.**—Unmarried persons without children, hired and serving for a year, gains a settlement. 3 William, c. 11. But must continue a whole year in such service. 8, 9 William c. 30. Serving a certificated member of a benefit society no settlement. 33 George III. c. 54, s. 24. Forty days' residence in the place necessary, but they need not be all together. Where the last forty days are in different places, settlement where the servant slept the last night. General hiring deemed hiring for a year. Hiring for a year, with liberty to be absent at harvest, sheep-shearing, &c. gains no settlement; but to serve a month in the militia does. Hiring for one day short of a year, no settlement. Serving for three hundred and sixty-five days, if leap year, no settlement. Hiring at so much per week, conditionally to part at a month's warning, deemed a general hiring; and as such, a hiring for a year.

4. **Serving Offices.**—Persons coming to inhabit a place, and executing any annual and public office for a year, settlement. 3 William c. 11, s. 6.

5. **Marriage.**—As a general rule, the wife follows the husband's settlement; but if the husband has no settlement, or it is not known at his death, her own settlement is restored. And if the husband deserts his wife, her settlement remains, except natives of Scotland, Ireland, the Isle of Man, Guernsey, or Jersey, who have no legal settlement, and may be sent home, on becoming chargeable, at the expense of the county.

6. **Estate.**—No person shall be removed from any estate while he remains on it. 9 George I. c. 7. But no person gains a settlement by an estate whose purchase was less than 30*l.* *Ibid.* Persons who have no settlement, as foreigners, or whose settlement cannot be known, as deserted infants, must be kept by the parish where they happen to be.

Removals.—So much of 13, 14 Charles II. c. 12, as enables justices to remove persons likely to become chargeable, is repealed; and no person can now be removed until actually chargeable. 35 George III. c. 101, s. 1. Justices may suspend removal of persons ill, either under a vagrant pass, or order of removal; expense attending the suspension to be paid by the parish officers of the place to which the pauper is to be removed; on refusal to pay within three days, to be recovered by distress and sale with costs not exceeding 40*s.* One justice. If out of the jurisdiction, warrant of distress to be backed by a justice having jurisdiction. Appeal to the sessions, if charges and costs exceed 20*l.* *Ibid.* s. 2. Every person convicted of larceny or felony, or deemed a rogue and vagabond, or disorderly person, or who shall appear to two justices, on oath of one witness, to be a person of evil fame or a reputed thief, and shall not give a satisfactory account of himself and way of living, and every unmarried woman with child, shall be deemed actually chargeable, and shall be removed as such. *Ibid.* s. 6. Persons refusing to go with an order of removal, or returning when removed, to be committed as a vagabond. One justice. 13, 14, Charles II. c. 12, s. 3. Parish officer refusing to receive a person so sent, to be bound to the assizes or sessions to answer the contempt. One justice. *Ibid.* If removed into another county or jurisdiction, and the parish officer refuse to receive, penalty 5*l.* Application to the parish of the place, from which the pauper is removed. Recovery by distress, and, in default, commitment for forty days. One justice of the jurisdiction to which removed. Two witnesses, 3 William, c. 11, s. 10. Appeal from orders of removal to the sessions of the county from which the pauper was removed. 8, 9 William, c. 30, s. 6. It must be to the sessions of the county, and not of any corporate town.

Poor's Rate, an assessment raised through England and Wales, for the temporary relief, or permanent maintenance, of all such persons as from age, infirmity, or poverty, cannot themselves procure the means of subsistence. The total sum raised by the poor's rate and other parochial rates within the year, ending Easter 1822, was 7,695,534*l.* of which 6,358,702*l.* were expended in support of the poor, and 1,336,632*l.* for other purposes. The poor's rate has gone on at an alarming increase since the peace in 1815, in which year 5,418,845*l.* were expended in their support.

POPE, Papa, Father, the sovereign pontiff, or supreme head of the Romish church.

POPULATION of the World, agreeably to a general census framed in the year 1825, from which it would appear, that under the metaphysical titles following, the whole human race are said to stand thus:—

Jews,	4,000,000
Pagans,	466,000,000
Mahomedans,	140,000,000
Christians,	200,000,000

Total, 800,000,000

Deists and Atheists are comprehended, but not distinguished in either of these enumerations, as they do not avow themselves by any formation into bodies, but are anomalies in each class.—It is worthy of notice, that the most ancient congregation, viz. Pagans, still subsist throughout the globe, and comprise more than one-half of its general population; that the second in order of time, viz. Jews, have, since the destruction of their temple and city, in A. D. 70, fallen so near to decay, as to comprise only a 200th part of the whole; that the third denomination, viz. Christians, now include one-fourth part of the whole; and that the Mahomedans, who sprung up six centuries after the Christians, and threatened to annihilate them, occupy the space of one-sixth part of the whole. It is also observable, that when an estimate of this kind was made about fifty years since, it was supposed that Christians amounted to one-sixth part, and now they have increased to one-fourth. A step further in this inquiry disposes of the Christians thus, in their subdivisions:—

The Greek and Eastern Churches,	30,000,000
Roman Catholics,	100,000,000
Protestants, including all sects,	70,000,000

Total, 200,000,000

Those have all arisen since the promoting of the Universal Christian Church, 4,000 A. M. of which—

The Western and Eastern Churches began and united in the.....	6th Century.
Their separation,.....	9th do.
Mahomed,.....	7th do.
Christianity in Great Britain,.....	7th do.
Darkness of Popery and Mahomedanism,....	6th to 16th do.
Waldenses,.....	12th do.
Wickliffe, Huss, and Jerome,.....	13th to 15th do.
Luther and Calvin,.....	16th do.
Reformation,.....	16th do.
Remonstrants,.....	17th do.
Protestant sects,.....	17th & 18th do.

It is unnecessary to enlarge this scale; the object is thus answered by showing the divisions of people, and their denominations and dates, by which any person, conversant in such researches, will find occupation enough for his reflection upon the probable state of mankind during the *ensuing half century*, under the advantages of an unexampled improvement in every country and condition, both in arts, navigation, and commerce, domestic and universal: an enriched acquisition of every embellishment of intellect, literature, and the fine arts; chemistry, and religious learning; an enlarged and liberal toleration in Church and State; a diffusion most unparalleled of the Holy Scriptures, of education, and a general intercourse among all nations.

In the lists of births and deaths in the kingdom of Bohemia, published for 1824, there is a considerable excess of births. In the capital, Prague, there were, out of 4436 deaths, 1633 of infants under a year old. The number of suicides was 105, or about one in forty. In London, in 1821, there were but 82 suicides out of 18,458 deaths, within the limits of the bills of mortality, or one in 225. In 1822 there were only 33 suicides in the bills of mortality. In Paris there were, in 1824, about 300 or 370, out of a population smaller than that of London: so false is the notion that we are, as compared with our neighbours, an eminently self-killing people. We are, in truth, not above a quarter part as suicidal as the people of Paris, and not much more than a sixth part so than the people of Prague.

POPULUS ALBA. (*White Poplar.*) This is a very ornamental tree. The leaves on the under surface are of a fine white, and on the reverse of a very dark green; and when growing on large trees are truly beautiful, as every breath of air changes the colour as the leaves move. The wood of all the species of poplar is useful for boards, or any other purpose, if kept dry. It is much in demand for floor boards for rooms, it not readily taking fire; a red-hot poker falling on a board, would burn its way through it, without causing more combustion than the hole through which it passed.

POPULUS MONILIFERA. (*Canada Poplar.*) This is also known by the name of Black Italian Poplar, but from whence it had this name we do not know. This species, which is the finest of all the kinds, grows very commonly in woods and hedges in many parts of Worcestershire and Herefordshire, where it reaches to prodigious sizes. Perhaps no timber is more useful than this; it is very durable, and easy to be converted to all purposes in building. The floors of a great part of Downton Castle, the seat of R. Payne Knight, Esq. are laid with this wood, which have been used forty years, and are perfectly sound. Trees are now growing on his estate which are three and four feet in diameter.

POPULUS NIGRA. (*The Black Poplar.*) Its Buds. The young buds or rudiments of the leaves, which appear in the beginning of spring, abound with a yellow, unctuous, odorous juice. They have hitherto been employed chiefly in an ointment, which received its name from them, though they are certainly capable of being applied to other purposes; a tincture of them, made in rectified spirit, yields upon being inspissated, a fragrant resin superior to many of those brought from abroad.

PORCELAIN, a fine sort of earthenware, chiefly manufactured in China, and thence called china-ware. The combination of siliceous and argillaceous earths is the basis of porcelain; and, with the addition of various proportions of other earths, and even of some metallic oxides, forms the different varieties of pottery, from

the finest porcelain to the coarsest earthenware.—Though siliceous earth is the ingredient which is present in largest proportion in these compounds, yet it is the argillaceous which more particularly gives them their character, as it communicates ductility to the mixture when soft, and renders it capable of being turned into any shape on the lathe, and of being baked. The clays are native mixtures of these earths; but they are often rendered unfit for the manufacture of at least the finer kinds of porcelain, from other ingredients which they also contain. The perfection of porcelain will depend greatly on the purity of the earths of which it is composed; and hence the purest natural clays, or those consisting of siliceous and argillaceous alone, are selected. Two substances have been transmitted to Europe as the materials from which the Chinese porcelain is formed, which have been named *Kaolin* and *Petunse*. It was found difficult to procure, in Europe, natural clays equally pure, and hence in part the difficulty of imitating the porcelain of the East. Such clays, however, have now been discovered in different countries; and hence the superiority to which the European porcelain has attained. The fine Dresden porcelain, that of Berlin, the French porcelain, and the finer kinds which are formed in this country, are manufactured of such clay, which from the use to which it is applied, has received the name of porcelain earth, and which appears, in general, to be derived from the decomposition of felspar of granite. It appears also that natural earths, containing magnesia, are used with advantage in the manufacture. The proportion of the earths to each other must likewise be of importance; and from differences in this respect arise, in part, the differences in the porcelain of different countries, as well as the necessity frequently of employing mixtures of natural clays. The argillaceous communicates tenacity and ductility to the paste, so that it may be easily wrought; the siliceous gives hardness and infusibility; and on the proper proportion of these depends, in a great measure, the perfection of the compound. The proportion of siliceous in porcelain of a good quality, is at least two-thirds of the composition; and of argillaceous, from a fifth to a third. Magnesia is of utility, by lessening the tendency which the composition of siliceous and argillaceous alone has to contract in baking, which is inconvenient in the manufacture.

PORCELAIN OF REAUMUR.—Reaumur gave the quality of porcelain to glass; that is, he rendered glass of a milky colour semi-transparent, so hard as to strike fire with steel, infusible, and of a fibrous grain, by means of cementation. The process which he published, is not difficult. Common glass, such as that of which wine bottles are made, succeeds best. The glass vessel which is to be converted into porcelain is to be enclosed in a baked earthen case or seggar. The vessel and case are to be filled with a cement composed of equal parts of sand and powdered gypsum or plaster, and the whole is to be put into a potter's kiln, and to remain there during the baking of common earthenware; after which the vessel will be found transformed into such a matter as has been described.

PORE, in Anatomy, a little interstice or space between the parts of the skin serving for perspiration. Pores are small interstices between the particles of matter which compose bodies; and are either empty, or filled with some insensible medium. Condensation and rarefaction are only performed by closing and opening the pores.

PORIME, PORIMA, in Geometry, a sort of lemma or theorem, so obvious or self-evident as to differ but little from an axiom or self-evident proposition.

PORISM, PORISMA, in Geometry, is a peculiar sort of proposition, which has been differently defined by different writers, some considering it as a general theorem or canon, deduced from a geometrical locus, and serving for the solution of other general and difficult problems; while others make it a lemma, or the same as porima. Dr. Simson defines it a proposition, either in the form of a problem or a theorem, in which it is proposed either to investigate or demonstrate. Euclid wrote three books of porisms, being a curious collection of various things relating to the analysis of the more difficult and general problems. Those books, however, are lost, and nothing remains in the works of the ancient geometers, concerning this subject, besides what Pappus has preserved, in a very imperfect and obscure state, in his "Mathematical Collections," viz in the introduction to the seventh book.

PORISTIC METHOD, in Mathematics, is that which determines when, by what means, and how many different ways, a problem may be resolved.

POROSITY, an essential property of bodies, is best ascertained by the microscope, which shews us the passage of fluids through solid bodies; or we may discover this property in the transmission of light in all directions through the internal structure of hard and solid bodies. The porosity of wood is very remarkable. Air may be blown by the mouth, in a profuse stream, through a cylinder two feet long of dried oak, beech, elm, or birch; and if a piece of wood, or a piece of marble, be dipped in water, and submitted to experiment under the receiver of a pneumatic machine, the air issuing through the exterior cavities will appear in a torrent of bubbles on the external surface. In like manner mercury is forced through a piece of dry wood, and made to fall in the form of a fine divided shower. If a few ounces be tied in a bag of sheep skin, it may be squeezed through the leather by the pressure of the hand, in numerous minute streamlets. This experiment illustrates the porosity of the human cuticle. From microscopic observations, it has been computed that the skin is perforated by a thousand holes in the length of an inch. If we estimate the whole surface of the body of a middle-sized man to be sixteen square feet, it must contain no fewer than 2,304,000 pores. These pores are the mouths of so many excretory vessels, which perform that important function in the animal economy, *insensible perspiration*. The lungs discharge every minute six grains, and the surface of the skin from three to twenty grains, the average over the whole body being fifteen grains of lymph, consisting of water, with a very minute admixture of salt, acetic acid, and a trace of iron. If we suppose this perspirable matter to consist of globules only ten times smaller than the red particles of blood, or about the 5000th part of an inch in diameter, it would require a succession of 400 of them to issue from each orifice every second. The permeability of a solid body to any fluid, depends however on its peculiar structure and its relation to the fluid. A compact substance will sometimes oppose the entrance of thin fluid, while it gives free passage to a gross one. Thus, a cask, which holds water, will permit oil to ooze through it; and a fresh humid bladder, which is air-tight, will yet, when pressed under water, imbibe a notable portion of that liquid. If a cylindrical piece of oak, ash, elm, or other hard wood, cut in the direction of its fibres, be cemented to the end of a long glass tube, water will pass freely through it, in divided streamlets; but a soft cork inserted into a similar tube will effectually prevent all escape of the liquid. Mercury may be carried in a small cambric bag, which could not retain water for a moment. If a circular bottom of close-grained wood, divided by a fine slit from the 30th to the 100th part of an inch wide, be cemented to the end of a glass tube, it will support a column of mercury from one to three or more inches high, the elevation being always proportional to the narrowness of the slit. Hence a cistern of box-wood is frequently used for portable barometers, the fine joints admitting the access and pressure of the air, but preventing the escape of the mercury. Yet a sufficient force would overcome this obstruction; and, in the same manner, the air which is confined in the common bellows under a moderate pressure, might, by a more violent action, be made to transpire copiously through the boards and the leather. The transmission of a fluid through a solid substance shews the existence of pores; but the resistance, in ordinary cases, to such a passage, is insufficient, therefore, to prove the contrary. The permeability of translucent substances to the rays of light, in all directions, evinces the most extreme porosity. But this inference is not confined merely to the bodies usually termed diaphanous; for the gradation towards opacity advances by insensible shades. The thin air itself is not perfectly translucent, nor will the densest metal absolutely bar all passage of light. The whole mass of our atmosphere, equal to the weight of a column of thirty-four feet of water, transmits, according to its comparative clearness, only from four-fifths to three-fourths of the perpendicular light, and consequently retains or absorbs from a fifth to a fourth of the whole. But this absorption is greatly increased by the accumulation of the medium. When the sun has approached within a degree of the horizon, and his rays

now traverse a tract of air equal in weight to a column of 905 feet of water, only the 212th part of them can reach the surface of the earth. By a peculiar application of my Photometer, I have found that half of the incident light, which might pass through a field of air of the ordinary density and 15½ miles extent, would penetrate only to the depth of fifteen feet in the clearest sea-water, which is therefore about 5400 times less diaphanous than the atmospheric medium. But water of shallow lakes, though not apparently turbid, betrays a greater opacity, insomuch, that the perpendicular light is diminished one-half, in descending only through the space of six, or even two feet. The same measure of absorption would take place in the passage of light through the thickness of two or three inches of the finest glass, which is consequently 500,000 times more opaque than an equal bulk of air, and even 300 times more opaque than a corresponding mass of that fluid. But even gold itself is diaphanous. If a leaf of that metal, either pure or with only an 80th part of alloy, and therefore of a fine yellow lustre, but scarcely exceeding the 300,000th part of an inch in thickness, and enclosed between two thin plates of mica, be held immediately before the eye, and opposite to a window, it will transmit a soft green light, like the colour of the water of the sea, or of a clear lake of moderate depth. This glaucous tint is easily distinguished from the mere white light which passes through any visible holes or torn parts of the leaf. It is indeed the very colour which gold itself assumes, when poured liquid from the melting pot. A leaf of pale gold, or gold alloyed with silver, transmits an azure colour; from which we may, with great probability, infer, that if silver could be reduced to a sufficient degree of thinness, it would discharge a purple light. These noble metals, therefore, act upon white light exactly as air and water, absorbing the red and orange rays, which enter into its composition, but allowing the co-joined green and blue rays to effect their passage. If the yellow leaf were estimated to transmit only the tenth part of the whole incident light, it would only follow, that pure gold is 250,000 times less diaphanous than pellucid glass. The inferior ductility of the other metals will not allow that fine lamination, which would be requisite for shewing, in ordinary cases, the transmission of light. But their diaphanous quality might be inferred from the tints with which they affect the transmitted rays, on being alloyed with gold. Other substances, though commonly reckoned opaque, yet admit in various degrees the passage of light. The window of a small apartment being closed by a deal board, if a person within shut his eyes a few minutes to render them more acute, he will, on opening them again, easily discern a faint glimmer issuing through the window. In proportion as the board is planed thinner, more light will be admitted, till the furniture of the room becomes visible. Writing paper transmits about a third part of the whole incident light, and when oiled it often supplies the place of glass in the common workshops. The addition of oil does not, however, materially augment the diaphanous quality of the paper, but renders its internal structure more regular, and more assimilated to that of a liquid. The rays of light travel, without much obstruction, across several folds of paper, and even escape copiously through pasteboard. Combining these various facts, it follows that all bodies are permeable, though in extremely different degrees, to the afflux of light. They must therefore be widely perforated, and in every possible direction. The porosity of bodies is consequently so diffuse, that the bulk of their internal kernel, or of the ultimate obstacles which they present, may bear no sensible proportion to the space which they occupy.

PORPHYRY, derives its name from the Greek word signifying red, as the porphyry used by the ancients was most frequently of that colour. The term porphyry is very vague, being applied to all rocks that have a compact base or ground in which crystals of any kind are imbedded and distinctly visible. Thus, according to the kind of stone in which the crystals occur, the porphyry takes its more appropriate name, as horn stone porphyry, clay-stone porphyry, pitch-stone, and obsidian porphyry, &c. The base of porphyry is generally allied to trap, and is fusible. The crystals are either quartz or felspar, but more commonly the latter, forming four-sided or six-sided prisms, whose length is greater than the breadth.

PORT, a harbour or haven on the sea-coast. *Bar Port*, is such as can only be entered with the tide. *Close Port*, is one within the body of a city, as the ports of Rhodes, of Venice, Amsterdam, Rochelle, Bayonne, and St. Jean de Luz. *Free Port*, is one open and free for merchants of all nations to load and unload their vessels in, without paying any duty or customs; such are the ports of Genoa and Leghorn. *Free Port*, is also used for a total exemption and franchise which any set of merchants enjoy, for goods imported into a state, or those of the growth of the country exported. Such was the privilege the English enjoyed for several years after their discovery of the port of Archangel, and which was taken from them on account of the regicide in 1648.

PORT, is also a name given, on some occasions, to the larboard or left side of the ship, as in the following instances:—*The Ship Heels to Port*, i. e. stoops or inclines to the larboard side. *Top the Main yard to Port*, the order to sway the larboard extremity of that yard higher than the other.

PORT, is also used for the burden of a ship.

PORT the Helm, the order to put the helm over to the larboard side of the vessel, when going large. In all these cases, this word appears intended to prevent any mistakes happening from the similarity of sounds in the words starboard and larboard, particularly when they relate to the helm, where a misapprehension might be attended with very dangerous consequences: accordingly the word larboard is never used in conning.

Half PORT, a kind of shutter, with a circular hole in the centre, large enough to go over the muzzle of the gun, and furnished with a piece of canvas, nailed round its edge, to tie upon the gun, whereby the water is prevented entering at the port, although the gun remains run out. They are principally used upon the main-deck, and particularly in ships carrying one tier of cannon.

PORT Bars, strong pieces of oak, furnished with two lanyards or ropes, by which the ports are secured from flying open in a gale of wind, the bar resting against the inside of the ship, and the port being firmly lashed to it by its two rings.

PORT-Last, or *Portoise*, is synonymous with Gunwale; as, *Lower the Yards a Port-last*, that is, down to the gunwale. *To Ride a Portoise*, is to have the lower-yards and top-mast struck, or lowered down, when at anchor in a gale of wind.

PORT Lids, a sort of hanging doors, to shut in the ports at sea; they are fastened by hinges to the upper edges, so as to let down when the cannon are drawn into the ship, whereby the water is prevented entering the lower decks. They are more generally termed **Ports**.

PORT Ropes, ropes made fast to the outside of the portlids, and communicating with a tackle within, by which the portlids are occasionally drawn up.

PORT Tackles, are those mentioned in the preceding article, as serving to haul up or open the ports.

PORT Holes, in a ship, are the holes in the side of the vessel through which are put the muzzle of the great guns. These are shut up in storms, to prevent the water from driving through them.

PORTA, JOHN BAPTISTA, a Neapolitan, eminent for his learning. As he admitted a society of learned friends into his house, he was accused of magical incantations, and exposed to the censures of Rome. He died 1515, aged 70. He invented the camera obscura, improved afterwards by Gravesande, and formed the plan of an encyclopedia. He wrote a Latin treatise on natural magic, 8vo.; another on physiognomy, mixed with astrology, &c.

PORTCULLIS, in Fortification, is an assemblage of several large pieces of wood, joined across one another like a harrow, and each pointed with iron at the bottom. They are sometimes hung over the gateway of old fortified towns, ready to let down in case of surprise, when the gates cannot be shut.

PORTEK, a kind of malt liquor which differs from ale and pale beer in being made of high-dried malt.

PORTGREVE, or **PORTGRAVE**, anciently called the principal magistrate in ports and other maritime towns. The word is formed from the Saxon "port," and "geref" a governor. It is sometimes also written "portreve." It is said by Camden,

that the chief magistrate of London was anciently called portgreve, which was exchanged by Richard I. for two baliffs; and these again gave place, in the reign of King John, to a mayor, who was an annually elected magistrate.

PORTLAND STONE, is a dull whitish species much used in buildings about London. It is composed of a coarse grit cemented together by an earthy spar.

PORTRAIT. See PAINTING.

PORTS, the embrasures or openings in the side of a ship of war, wherein the artillery is ranged in battery upon the decks, above and below. *Gun-room Ports*, are situated in the ship's counter, and are used for stern-chases, and also for passing a small cable or a hawser out, either to moor, head and stern, or to spring upon the cable, &c. *Lower-deck Ports*, are those on the lowest gun-deck. *Middle deck Ports*, are those on the second or middle gun-deck of three-deckers.

POSITION, or the *Rule of False Position*, otherwise called the Rule of Falsehood, in Arithmetic, is a rule so called because in calculating on several false numbers taken at random, as if they were the true ones, and from the differences found therein, the number sought is determined. The rule is either single or double.—**Single Position**, is when there happens in the propositions some partition of numbers into parts proportional, in which case the question may be resolved at one operation, by this rule: Imagine a number at pleasure, and work therewith according to the tenor of the question, as if they were the true number; and what proportion there is between the false conclusion and the false proportion, such proportion the given number has to the number sought. Therefore the number found by augmentation, shall be the first term of the rule of three; the second number supposed, the second term; and the given number, the third. Or the result is to be regulated by this proportion, viz. As the total arising from the error, to the true total, so is the supposed part to the true one. Example: A, B, and C, designing to buy a quantity of lead to the value of 140*l*. agree that B shall pay as much again as A; and C as much again as B; what must each pay. Now suppose A to pay 10*l*. then B must pay 20*l*. and C 40*l*. the total of which is 70*l*. but it should be 140*l*. Therefore, if 70*l*. should be 140*l*. what should 10*l*. be? Answer, 20*l*. for A's share, which doubled makes 40*l*. for B's share, and that again doubled, gives 80*l*. for C's share, the total of which is 140*l*.—**Double Position**, is when there can be no partition in the numbers to make a proportion. In this case, therefore, you must make a supposition twice, proceeding therein according to the tenor of the question. If neither of the supposed numbers solve the proportion, observe the errors, and whether they are greater or less than the supposition requires, mark the errors accordingly with the sign + or —. Then multiply contrariwise the one position by the other error; and if the errors are both too great or both too little, subtract the one product from the other, and divide the difference of the products by the difference of the errors. If the errors are unlike as the one + and the other —, add the products, and divide the sum thereof by the sum of the errors added together, for the proportion of the excesses or defects of the numbers supposed to be the number sought; or the suppositions and their errors being placed as before, work by this proportion as a general rule, viz. as the difference of the errors if alike, or their sum if unlike, to the difference of the suppositions, so either error, to a fourth number; which accordingly added to or subtracted from the supposition against it, will answer the question.—Such are the instructions commonly given in books of arithmetic on this subject; but it were certainly better to abandon all these rules, and solve questions of this stamp by means of equations and algebraic analysis. Thus, let us take the example before us, in single position, as it is called; and

Let $x = A$'s share; $2x = B$'s share; $4x = C$'s share; then, by the question $x + 2x + 4x = 140$, or $7x = 140$
 $\therefore x = \frac{140}{7} = £20$ for A's share, which doubled makes £40

for B's share; and this last doubled gives £80 for C's share. Any person capable of handling an equation, may thus work out questions in position, without staring at the supposed wisdom and ability of a poor pedagogue bringing out the answer by trials

Example. What number is that which, being multiplied by 6, the product increased by 18, and the sum divided by 9, the quotient shall be 20.

Let the two supposed numbers be 18 and 30.

$$\begin{array}{r} \text{Then } 18 \\ 6 \end{array}$$

$$\begin{array}{r} 108 \\ 18 \end{array}$$

$$9) 126$$

14 the 1st result.

$$\begin{array}{r} 30 \\ 6 \end{array}$$

$$\begin{array}{r} 180 \\ 18 \end{array}$$

$$9) 198$$

22 the 2d result.

Then $22 - 14 : 30 - 18 :: 20 - 14$

Or, $8 : 12 :: 6 : 9$, the correction to 1st supposition; therefore $9 + 18 = 27$, the number sought. By Algebra,

Let $x =$ the number sought; then $\frac{x \times 6 + 18}{9} = 20$ by the question; i.e. $x \times 6 + 18 = 180$, or $6x + 18 = 180$. By transposition, $6x = 180 - 18 = 162$, or $6x = 162$, therefore $x = \frac{162}{6} = 27$.

POSITION, in Astronomy, relates to the sphere. The position of the sphere is either right, parallel, or oblique; whence arise the inequality of days, the difference of seasons, &c.

Circles of POSITION, are circles passing through the common intersections of the horizon and meridian, and through any degree of the ecliptic, or the centre of any star, or other point in the heavens, used for finding out the position or situation of any star. These are usually counted six in number, cutting the equator into twelve equal parts, which the astrologers call the celestial houses.

Centre of POSITION. See CENTRE.

Given in POSITION, in Geometry, is an expression made use of to denote that the position or direction of a line is given or known.

Geometry of POSITION, is a species of geometry first treated of by Carnot, the object of which is to investigate and determine the relation that has place between the position of the different parts of a geometrical figure with regard to each other, or with regard to some determinate line or figure first fixed upon as a term of comparison, and which is called the primitive system, while that compared with it is denominated the transformed system; and as long as the different parts of the transformed system have the same directions or positions with regard to each other, their relation is said to be *direct*, but when they are different, *inverse*.

POSITIVE ELECTRICITY. In the Franklinian system, all bodies supposed to contain more than their natural quantity of electric matter, are said to be positively electrified; and those from whom some part of their electricity is supposed to be taken away, are said to be electrified negatively. These two electricities being first produced, one from glass, the other from amber or rosin, the former was called vitreous, the other resinous, electricity.

POSITIVE QUANTITIES, in Algebra, are those which are affected with the sign + being affirmative or additive, in contradistinction to negative quantities, which are to be subtracted.

POSSESSION, is two-fold; actual, and in law. Actual possession, is when a man actually enters into lands and tenements to him descended. Possession in law, is when the lands and tenements are descended to a man, and he has not as yet actually entered into them. Staundf. 198.

POST, a military station. Thus the detachments established in front of the army are termed out-posts; the stations on the wings of the army are said to be posts of honour, as being the most conspicuous and most exposed. But in the operations of a campaign, a post properly signifies any spot of ground capable of lodging soldiers, or any situation, whether fortified or not, where a body of men may make a stand, and engage the enemy to advantage. The great advantages of good posts, in war, as well as the mode of securing them, are only learned by experience. Barbarous nations disdain the choice of posts, or

at least are contented with such as immediately fall in their way, they trust solely or chiefly to strength and courage; and hence the fate of a kingdom may be decided by the event of a battle. But enlightened and experienced officers make the choice of posts a principal object of attention. The use of them is chiefly felt in a defensive war against an invading enemy; as by carrying on a war of posts in a country where this can be done to advantage, the most formidable army may be so harassed and reduced, that all its enterprises may be rendered abortive. In the choice of a post, the general rules to be attended to are, that it should be convenient for sending out parties to reconnoitre, surprise, or intercept the enemy; that if possible it may have some natural defence, as a wood, a river, or a morass, in front or flank, or at least that it be difficult of access, and susceptible of speedy fortification; that it shall be so situated as to preserve a communication with the main army, and have covered places in the rear to favour a retreat; that it may command a view of all the approaches to it, so that the enemy cannot advance unperceived and rest concealed, while the detachment stationed in the post are forced to remain under arms; that it is not commanded by any neighbouring heights; and is proportioned in extent to the number of men who are to occupy and defend it. It is not to be expected that all these advantages will often be found united; but those posts ought to be selected which offers the greatest number of them.

Post, a conveyance for letters or despatches. The present establishment of the general post-office of Great Britain consists of a postmaster-general, to the duties of which station there have, for many years past, been two persons appointed, under the title of joint postmasters-general; a secretary; upwards of 150 assistants and clerks for the head letter-office in London, under the direction of a superintending president of the inland-letter department; and a comptroller of the foreign-letter office. Near 600 deputy postmasters throughout the kingdom, act under one principal, and nine riding surveyors. There are also distinct offices and clerks, acting under an accountant-general and a receiver-general; as well as a separate establishment for the two-penny, formerly the penny post, which, since the abolition of Mr. Palmer's appointment of surveyor and comptroller-general, has been new-modelled and greatly improved in all its branches. There is likewise a post-master-general of Scotland, with a secretary, comptroller, surveyor, and a separate establishment of all the requisite officers and clerks at Edinburgh, acting under the orders of the joint postmasters-general in London. The annual expense of management is about 350,000*l.* and the gross produce exceeds 1,300,000*l.* a year.

Post, Two Penny, a post established for the benefit of London and other parts adjacent, whereby any letter or small parcel is speedily and safely conveyed to and from all places within the bills of mortality, or within ten miles of the city. It is now managed by the general post-office, and receiving houses are established in most of the principal streets, for the more convenient transmission of letters.

Post, a particular mode of travelling. A person is said to travel post, in contradistinction to common journey travelling, when, in place of going on during his whole journey in the same vehicle, and with the same horses, he stops at different stages, to provide fresh horses or carriages, for the sake of greater convenience and expedition. As he thus uses the same mode of travelling that is employed for the common post, he is said to travel post, or in post, i.e. in the manner of a post.

Post Disseisin, a writ for him that, having recovered land or tenements by præcipe quod reddat, upon default of reddition, is again disseised by the former disseisor.

POSTEA, is the return of the proceedings by nisi prius into the court of Common Pleas after a verdict, and there afterwards recorded. Plowd. 211.

POSTERN, in Fortification, is a small gate generally made in the angle of the flank of a bastion, or in that of the curtain, or near the orillon, descending into the ditch; by which the garrison may march in and out unperceived by the enemy, either to relieve the works or to make private sallies, &c.

POSTULATE, in Geometry, a demand or petition, or a supposition so easy and self-evidently true, as needs no explanation or illustration; differing from an axiom only in the manner in which it is put, viz. as a request, instead of an assertion.

POTASS. This alkali is commonly called the vegetable alkali, because it is obtained from the ashes of vegetables. It has been discovered by Sir H. Davy to consist of a metal which he calls potassium, and two portions of oxygen and water. In the fashionable nomenclature of the day, it is called the hydrated deutoxide of potassium. In the arts of life, and indeed even in scientific investigations, we are not so much concerned with potassium, as with this very common and useful alkali in the state in which we find it.

Table of the saline product of one thousand lbs. of potass of the following vegetables:—*Saline Products.*—Stalks of Turkey wheat or maize, 198 lbs.; stalks of sunflower, 349 lbs.; vine branches, 162·6 lbs.; elm, 166 lbs.; box, 78 lbs.; sawlow, 102 lbs.; oak, 111 lbs.; aspen, 61 lbs.; beech, 219 lbs.; fir, 133 lbs.; fern cut in August, 118 lbs.; or 125, according to Wildenheime; wormwood, 748 lbs.; fumitory, 360 lbs.; heath, 115 lbs. Wildenheime. In both cases a high-coloured liquor is separated, which is to be poured off; and the potash must be kept carefully secluded from air. A perfectly pure solution of potash will remain transparent on the addition of lime-water, show no effervescence with diluted sulphuric acid, and not give any precipitate on blowing air from the lungs through it by means of a tube. About 100 parts of pure potass are equivalent to 70 of concentrated sulphuric acid; therefore a good alkalimeter may be made by having a graduated tube, which divided into 100 equal parts, let 70 be filled with acid and the rest with pure water. If the alkali be quite pure, it will require the whole liquid in the tube to saturate 100 of the alkali; but if less will be sufficient, such as 75 parts, then we know that there are only 75 per cent. pure alkali; and so on for any other proportion.

POTASSIUM is the metallic basis of potass, and may be obtained by placing hydrate of potass between two discs of platinum connected with the extremities of a powerful voltaic apparatus, when it will undergo fusion, and the oxygen will be separated, and the metallic globules will appear at the negative surface. When newly cut, it is splendid like silver, but soon tarnishes in the air, on which account it must be kept in a phial in pure naphtha. When thrown into the water, it swims on the surface, burning with a beautiful red mixed with violet. It combines with oxygen in different proportions.

POTATOES. The potatoe is the bulb that contains the largest quantity of soluble matter in its cells and vessels; and it is of most importance in its application as food. Potatoes in general afford from one-fifth to one-seventh their weight of dry starch. (*Solanum Tuberosum*, Linn.)

Saintmare's mode of Distilling from Potatoes.—The intention of Saintmare is to distil alcohol from potatoes, and the subject of his improvement is described under two heads; viz. the mode of preparing the potatoes, ready to be converted into wash, and the general arrangement of the apparatus for conducting the fermentation and distillation, so as to retain the natural flavour of the spirit, and at the same time economize the use of fuel. It is first proposed to wash the potatoes free from the earth which adheres to their skins, by placing them in a rotatory drum, formed by open rails or staves, which drum is immersed in a trough or other vessel filled with water. When thus cleansed, the potatoes are to be introduced into a mill, for the purpose of being ground to a pulp. The construction of the mill to be employed is rather peculiar; it consists of a box, as usual, containing a cylinder having ribs of iron set into the periphery of the cylinder, which ribs are to be notched, or formed on the outside into teeth like fine saws. Two pieces of wood at right angles, the one standing in a perpendicular, the other in a horizontal direction, are to be brought up against the cylinder on one side, and the potatoes, introduced from a hopper above, are let fall between the cylinder and the wood, when, by the rotation of the cylinder, at the rate of about four hundred revolutions per minute, the potatoes become ground to a pulp, which descends into a receptacle below, there being a wooden scraper behind the cylinder, in order to prevent the pulp from adhering. The perpendicular piece of wood is made to give way by means of a spring behind it, for the purpose of allowing the larger potatoes to come in contact with the cutting cylinder, and the horizontal piece of wood is adapted with screws, in order to keep it up constantly against the cylinder which wears away the wood as it revolves.

The pulp of the potatoes thus produced in the mill, is now to be mixed with a considerable quantity of water, sufficient to bring it into a liquid state; it is then strained through a sieve, and such portions of the potatoe as will not pass through the sieve are rejected as useless, and set apart for feeding animals. The liquor thus strained, is then to be poured into a sort of cullender, or vessel having many holes, which vessel is lined with a cloth; and here the pulp is allowed to settle, and the water to drain away, leaving the substance of the potatoe in a cake at bottom. This cake is then laid out upon a plaster floor, that its moisture may be drawn out by absorption, and afterwards it is dried in a kiln, where it may be kept perfectly good for a very great length of time.

In commencing the process of distillation from the prepared potatoes, the cake must be first broken and dissolved, by mixing with hot water till it has assumed the consistency of cream. A quantity of this liquor is then placed in a vat, which may be supposed to be situated as shown at *a*, fig. 1. This figure shows the whole range of apparatus in action, from the vat *a*, in which the pulp is first introduced previous to fermentation, down to the worm where the distilled spirit is ultimately condensed.

Let the quantity of potatoe pulp introduced into the vat *a*, be equal to about three hundred weight when in a dry state, but mixed in the vat with hot water, to about the consistency of cream, as before mentioned; let there be water poured into the vessel *b*, until it rises above six inches from the bottom, and into this water introduce twenty pounds of sulphuric acid, observing that the vessel, *b*, should have a lining of lead, to prevent the action of the acid upon the wood. The cock of the vat *a* is now to be opened, and the liquor contained therein allowed to flow into the vat, *b*, which is called the decomposing vessel. Another portion of the potatoe pulp may then be mixed in the vat, *a*, and let off into the vat, *b*, as before; and so on until the vat, *b*, is sufficiently full. The proportion of acid to the pulp, necessary for decomposing it, should be from two to three pounds of the former, to every hundred weight of the latter.

Steam is now to be sent into the vat *b*, through the pipe *c*, from a boiler, and by means of this steam the liquor in *b*, is made to boil, and is to be kept boiling for four or five hours. The steam which evaporates from the vat, *b*, is allowed to pass up a worm pipe in the tub, *d*, which by that means heats the water in the tub, so that none of the heat is lost, and hot water may then be drawn from the tub, through a pipe, to supply the vat *a*.

After the boiling in the decomposing vessel is complete, the liquor is let off into a third vat, *c*, which is called the saturating vessel. During the time that the liquor is flowing into this vessel, a quantity of lime and water, or chalk and water, is introduced, in order to neutralize the sulphuric acid; two or three pounds of chalk is generally sufficient for one of acid, but the introduction of the chalk or lime must be continued as long as any effervescence arises from the liquor.

When the liquor has subsided in the saturating vessel, it is to be drawn off into the fermenting vat, *f*, where a quantity of yeast is added, to promote the fermentation. The temperature of this vessel is to be kept up to about ninety or one hundred degrees of Fahrenheit's thermometer, and the room in which the operation is going on, to eighty or eighty-five degrees, during the whole time of its fermenting, which usually takes fifteen or twenty days. To facilitate the fermentation, hydrogen gas is

proposed to be injected into the liquor, by means of a force pump through the pipe *g*, which has a number of small holes in the lower part of the pipe, branches from which are coiled about the bottom; but this injection need not be made when the carbonic acid gas, which escapes, contains an excess of hydrogen. This mode of introducing hydrogen into the wash, may be advantageously employed to facilitate fermentation, whenever liquor is intended for distillation. The sediment of the vat, *e*, should be stirred up, to prevent the loss of any saccharine matter, and allowed to run into the fermenting vat.

When the process of fermentation is complete, the liquor is to be run from the vat *f*, into the still, *k*, through the pipe, *i*, and is then to be operated upon in the usual way. The form of this still is, however, something different from those stills commonly used; it is without the usual hand, and it is here intended that the evaporation shall pass up the long tube, *k*, in doing which, it will become partially condensed, and run down again into the still; but the more volatile or spirituous part will pass over the neck at top, and proceed down the pipe to the worm *l*, immersed in cold water, where it will become condensed, and discharge itself at the extremity of the pipe into any vessel placed under it.

The produce of this first distillation is called low wine; it is therefore necessary to pass the liquor again through the still before it becomes a highly concentrated spirit. For this purpose it is to be carried to another still shewn at *a*, fig. 2. Here

Fig. 2.

the operation of distilling is conducted in the ordinary way, and the spirituous vapour passing up the pipe, *b*, descends into the closed vessel *c*, which is cooled by a reservoir of cold water, in a trough, *d*, at top. Here the spirit boils, and as it rises passes up the pipe, *e*, and descends into a long cylindrical vessel, *f*. This vessel is immersed in a trough of cold water, and is divided by partitions into six compartments, having small bent pipes leading from one to the other. The heaviest portion of the spirit condenses in the first compartment, and the volatile part proceeds through the pipe to the next, where the second heaviest becomes condensed, and the lightest passes through all the compartments, and proceeds through the pipe, *g*, to the worm immersed in the tub, *h*, from whence it discharges itself into a suitable receiver.

The spirit condensed in the cylindrical vessel, *f*, may be passed through the small pipes at the bottom of each compartment into the long pipe, *i*, and from thence drawn off for rectification, or it may be passed from the long pipe into the closed vessel, *c*, and from thence through the pipe *k* to the still for further distillation.

The specification concludes by stating, that the invention consists, first, in the process by which a spirituous liquor is obtained or extracted from potatoe; and, secondly, in the improved arrangement and construction of apparatus for effecting the processes of fermentation and distillation. [Inrolled Sept. 1824.]

Another Method of obtaining Brandy from Potatoes is this.—The potatoes are put into a close wooden vessel, and there boiled by steam, which is communicated to them at a degree little above that of boiling water; after they are boiled or steamed, they are reduced to a paste with extraordinary facility, (which is done by machinery in the interior of the wooden vessel;) they then add boiling water to the paste, and a little potash rendered caustic by quicklime; the addition of the alkali is to dissolve the vegetable albumen, which prevents the complete conversion of the potatoes into starch. The starch liquor, after being filtered and evaporated, gives a residue very pure, and susceptible of being treated chemically: we are then

directed to draw off the brandy from the potatoes, which has the proper herbaceous taste: it is then mixed with chlorate of lime, by which process the brandy is rendered equal to that distilled from wine. It will be observed that there is some difference between this process of obtaining spirits from potatoes, and that described in the immediately preceding article.

POTENTILLA ANSERINA. (*Silverweed.*)—The sensible qualities of Anserina leaves promise no great virtue of any kind; for to the taste they discover only a slight roughness, from whence they were thought to be entitled to a place among the milder corroborants. As the astringency of tormentil is confined chiefly to its root, it might be thought that the same circumstance would take place in this plant; but the root is found to have no other than a pleasant sweetish taste, like that of parsnip, but not so strong.

POTENTILLA Reptans. (*Cinquefoil, or Five Leaved Grass.*)—The root is moderately astringent; and, as such, is sometimes given internally against diarrhoeas and other fluxes; and it is employed in gargarisms for strengthening the gums, &c. The cortical part of the root may be taken, in substance, to the quantity of a dram; the internal part is considerably weaker, and requires to be given in double the dose, to produce the same effect. It is scarcely otherwise made use of than as an ingredient in Venice treacle.

POTERIUM Sanguisorba. (*BURNET.*)—This plant grows in calcareous soils, and is in some places much esteemed. On the thin chalky soils near Alresford in Hampshire, I have observed it to thrive better than almost any other plant that is cultivated. Sheep are particularly fond of it, and I have heard it said that the flavour of the celebrated Lausdown mutton arises from the quantity of burnet growing there. It is also the favourite food of deer. This will grow well in a calcareous soil, and there are few pastures but would be benefited by its introduction. Twenty-five pounds per acre are sown alone; eight pounds, mixed with other seeds, would be sufficient to give a good plant on the ground.

POTTERY, the art of making vessels from earth, is of the remotest antiquity. In the earlier ages of the world, almost all domestic utensils were of pottery, which may hence be fairly supposed the oldest of mechanical inventions. The Scriptures first mention the practice of this art. The numerous remains of Greek and Etruscan vases, prove that these nations were celebrated for their skill in pottery. The Greek vases in Sir William Hamilton's collection, deposited in the British Museum, are ornamented with truly elegant paintings, and their forms are equally simple and beautiful. Porcelain, (from the Portuguese word, *porcelena*, a cup,) the most perfect species of earthenware, is distinguished from the inferior kinds of pottery, which are opaque and of various colours, by its being white and semi-transparent. Europe has now excelled the Oriental nations in the art of making porcelain. Besides the manufactory of Saxony, which has been long established, porcelain is made at Vienna, at Frankendal, and lately in the neighbourhood of Berlin. In France, the Serres porcelain holds the most distinguished rank. Italy also has its porcelains, the best of which are those of Naples and Florence. The potteries of England have made rapid advances towards perfection. The chief establishments are in Staffordshire, at Derby, Worcester, Coalport, and Liverpool. The Staffordshire potteries have long been celebrated for their earthenwares, and some of the principal proprietors have directed their attention to the manufacture of porcelain, which has attained a high degree of excellence. The earthenwares formerly manufactured here were coarse; the finest sort was an imperfectly white ware, very slightly ornamented with blue, and glazed by throwing into the oven, while the ware was firing, a quantity of common salt; the salt was converted into vapours, and, applied to the surface of the vessels, formed the glazing. The colour of the body of this kind of ware is said to have received considerable improvement from the following incident: Mr. Astbury, a Staffordshire potter, travelling to London, perceiving something amiss with one of his horses' eyes, a hostler at Dunstable offered to cure the animal, and for that purpose put a common black flint stone into the fire. When taken out, it was observed to be of a fine white; the potter immediately conceived the idea of improving his ware, by adding this

material to the whitest clay he could obtain. He sent home a quantity of the flint stones, and, by mixing them with tobacco-pipe clay, produced a white stone ware superior to any that had been made before. The other potters followed his example.—In 1763, Wedgwood invented a species of earthenware new in its appearance, and covered with a rich and brilliant glaze, called queen's ware. Hence may be dated a new era in this interesting and important manufacture. Wedgwood's ware evinces considerable taste in the elegance of his antique models, and in the excellence of their execution. Spode's ware, or blue and white, in imitation of the Oriental china, or porcelain, has been introduced with great success in various manufactories. The potteries in Staffordshire are not less than one hundred in number; employing more than ten thousand persons; and the annual value of goods manufactured there, may be estimated, in the most flourishing times, at eight hundred thousand pounds sterling. A canal furnishes the manufacturers with the means of water-carriage to every principal sea-port in the kingdom; greatly facilitating the exportation of the manufactured articles, and the importation of the raw material. The number of persons employed in Spode's establishment amounts to more than seven hundred, and the latest discoveries in machinery are applied to the advancement of the art.

We now proceed to describe the general processes pursued at Spode's manufactory, and which may be classed thus:—Preparations of the raw material—moulding and turning—firing—printing—glazing—and painting.

In the preparation of the raw material, a powerful steam-engine performs many of the processes formerly carried on by manual labour. The bodies of earthenware are composed of Kent flint and West of England clay. The flint is first calcined in kilns, similar to those in which lime is burnt; it is then broken by revolving hammers, put in motion by the steam-engine, and afterwards conveyed into the pans, paved with stone, to be ground with water. In the centre of the pans there is an upright shaft, from which several transverse arms branch out, having very heavy stones placed between them; these stones, moved horizontally by the steam-engine, grind the flints, until they form a cream-like liquid, which is let off into the wash-tub, where the coarser particles are separated from the fine; the latter runs off into reservoirs, and the former is carried back to the grinding pan. When the ground flint is wanted for use, it is conveyed from the reservoir by a pump worked also by the steam-engine.

The process of preparing the clay, and mixing it with the flint, is this:—The clay is drawn up into the upper chamber of the slip-house, and there thrown into an iron box, in which moves a shaft, with knives fixed in it, to cut the lumps into small pieces. The clay is now laid in a cistern with a proper quantity of water, where it softens, and is then put into the plunging-tub; in this tub the water and clay are stirred until they become thoroughly mixed. The liquid is now drawn off into another cistern, from which it passes through a silk sieve into a third cistern, then into a fourth, through silk sieves still finer, the ground flint and other ingredients are now brought and mixed together; and the whole passes through sieves of a greater degree of fineness, into a fifth cistern: in this is a pump that throws it into a trough for conveying it to the drying kiln. All these various operations are worked by the steam-engine, and there are fourteen sieves in motion at one time. After the clay has been dried, it is taken from the kiln and laid together in large heaps, and before it is worked into the vessels for which it is destined, the air-bubbles are disengaged from it. This is done by a machine turned by the steam-engine; the machine is an iron box shaped like an inverted cone, with an upright shaft in its centre, to which are affixed knives to cut the clay which is put into the box, by their rotatory motion; and, at the same time, so arranged, as to force it downwards to a square aperture at the bottom, it escapes through this in a sufficiently compressed state for the workmen, and is then cut into square pieces of a convenient size to be distributed in the manufactory. Near the steam-engine are work-shops for those branches of the trade which require the aid of machinery; and in this building there are eight throwing wheels, and twenty-five turning lathes. Underneath these

shops are drying-houses, heated by steam, in which the ware is dried, previously to its going to the oven to be fired; above the work-shops is a single room capable of holding two hundred workmen.

Moulding and Turning.—Tea-cups, saucers, basons, jugs, and such like vessels, receive their first shape from the hands of the thrower, who sits on a stool with a flat circular wooden wheel before him, moving horizontally on a pivot. This wheel is set in motion by the steam-engine, and the workman can increase or diminish its velocity as there is occasion. Upon the centre of the wheel the operator throws a lump of clay, of the required size, and forms it into almost any shape with the utmost facility: it is then cut from the wheel by a wire, and taken to be dried, that it may acquire sufficient hardness to fit it for the next operation. By turning, the superfluous parts of the clay are taken off, so as to render the article perfectly smooth, and to give it the exact shape. The lathes on which the vessels are turned, are also put in motion by the steam-engine, and regulated as to speed by the turner himself. The principle of turning earthenware is very similar to that employed in wood-turning.—The vessels requiring handles and spouts, are taken to the handling room, and those which do not want this appendage, after having attained the requisite hardness, are sent to the oven to be baked. The handles, made on a mould of plaster of Paris, are fixed to the vessel with a liquid mixture of the same material as the vessel itself.

For the formation of various articles manufactured in all potteries, moulds made of plaster of Paris are necessary. The modeller forms the shape of the intended vessel out of a solid lump of clay, which after receiving his finishing touches, is handed to the person who makes the plaster mould from it. Plates and dishes are made from moulds of this kind, upon which the operator lays a piece of clay of the length, breadth, and thickness required; the mould and clay are then placed upon a wheel turning horizontally on a pivot, and the operator keeps peeling round with the left hand, and presses the clay to the shape of the mould with the other. The mould and dish together are then carried into a stove moderately heated, where it remains until sufficiently dried to separate. The plate or dish is then cut even at the edges, and in other respects finished: before they are baked, the dishes are laid flat upon plaster or stone flags that are quite level, in order that they may remain straight until they go to the oven to be fired. Tureens, vegetable dishes, and such articles, are also made in moulds, but require more time and care, being less simple in their form. Figures, flowers, and foliage in bas-relief, are also formed separately in moulds, and afterwards affixed to the vessel with diluted clay.

Firing.—When the ware is ready for firing, it is placed in clay cases called saggars, which vary in size and shape according to the articles placed in them. The saggars are put into an oven, shaped like a bee-hive, with an opening at the top; there is also an opening at the side to admit the saggars, but this is closed before the fire is applied. Each sagger is luted to the other by a roll of soft fire-clay. This secures the vessels contained in them from dust, the fumes of the fires, and from the effects of the air when the oven is cooling. The fires which heat the oven are placed round it in proper receptacles, which communicate with the interior of the oven by flues, heating every part equally. This first firing gives a higher degree of heat, and is continued much longer than any successive firing; when once fired, the article is called biscuit-ware. The cream-coloured, or queen's-ware, is now carried to the dipping-house to receive its glazing; that which is to be printed blue is taken to the printing-house.

Printing.—The design is previously engraven on a copper-plate, and laid on a stone to warm. The colour (which has oxide of cobalt for its basis) is mixed with a preparation of oils, to fetch out the impression. This mixture is smeared over the surface of the plate, and again cleaned off, leaving the liquid in the engraving only. The paper used to take off the impression is made expressly for this purpose; it is damped, laid on the copper-plate, and passed between two iron-rollers, as in ordinary copper-plate printing. The design being transferred to the paper, is laid immediately upon the ware, being rubbed on with a flannel. After remaining a short time, the

ware is put into a tub of water, and the paper is separated from it with a sponge, leaving the design in the most perfect state. The ware is then dried, and taken to the oven to be burned; during this operation, the oil which has been mixed with the colour in the printing is destroyed, and the oxide of cobalt more firmly attached to the ware: it is then glazed.

Glazing.—The glaziers differ in their composition in all manufactories; most, however, have oxide of lead for their basis. The ingredients being mixed with water, and well ground, the glaze is ready for use, in which the vessels are dipped. On drying, which takes place instantly, the water contained in the glaze being absorbed by the porosity of the vessel, it is covered with a fine white powder of a regular thickness; this, when fired, becomes vitreous, or assumes a glass-like appearance, and from its transparency, the blue pattern underneath is rendered perfectly visible. In the last firing, especial care is taken to keep one piece from touching the other, or the whole would fuse into one united mass. Great attention is also requisite in the firing, not to give too much or too little heat, either extreme being injurious; the fireman in this, as in the other firing, draws out trial pieces from the oven, with an iron rod, to ascertain the proper degree of heat.

Painting.—The pieces of porcelain or earthenware to be enamelled and enriched by gilding are, after the first firing, dipped in a suitable glaze, and again submitted to the fire. They are then delivered to the painter or enameller. The colours used in enamel-painting are composed of metallic calxes, and fluxes suitable to each colour, separately and conjointly, and of such a nature as to fuse them sufficiently for the glazing on which they are laid. Gold has also its flux, and is laid on as the other colours are. When the painting is completed, the ware is placed in a furnace less in size, and different in construction, from that before noticed. Care is here necessary in the arrangement of the vessels, and great nicety is required in the degree and the continuation of the heat, which is not so intense as in the former firings. The colours, after this firing, put on a shining appearance, but the gold has an opaque yellow cast, and is burnished with a blood-stone, to give it the desired brilliancy.

The processes already detailed for the manufacture of earthenware, are applicable, in nearly every case, to that of porcelain. The composition of the bodies and glazes is, of course, different; and much greater care is necessary in every process, than is bestowed upon earthenware in general.

Delft ware, so called because first made at Delft, in Holland, is a kind of pottery of baked earth, covered with a white glazing, which gives it the appearance of porcelain. The basis of this pottery is clay mixed with a certain quantity of sand; the vessels are slightly baked, so that they resist a sudden application of heat; and they are, lastly, covered with an enamel or glaze, which is composed of common salt, sand ground fine, and the oxides of lead and tin. The latter gives a white opaque colour to the mass. The furnace and colours used for painting this ware, are the same as those which have been noticed as employed for porcelain. See PORCELAIN.

POUNCE, gum sandarach pounded and sifted very fine, to rub on paper, in order to preserve it from sinking, and to make it more fit to write upon. Pounce is also a little heap of charcoal dust, enclosed in a piece of muslin or some other open stuff, to be passed over holes pricked in a work, in order to mark the lines or designs on paper, silk, &c. placed underneath; which are to be afterwards finished with a pen and ink, a needle, or the like.

POUND, an English weight of different denominations, as, Avoirdupois, Troy, Apothecaries, &c. The pound avoirdupois is 16 ounces of the same weight, but the other pounds are each equal to 12 ounces. The pound avoirdupois is to the pound troy as 5760 to 6999, or nearly as 576 to 700. See MEASURES.

POUND is also the highest denomination used by the English in their money accounts, being equal to 20 shillings.

POURSUIVANT, or **PURSUIVANT**, in Heraldry, the lowest order of officers at arms. The pursuivants are properly attendants on the heralds, when they marshal public ceremonies.

POWDER CHESTS, among sailors, certain small boxes charged with powder and old nails, &c. and fastened occa-

sionally on the decks or sides of merchant-ships, when furnished with close-quarters, having a train of powder which communicates with the inner apartments, so as to be fired at pleasure to annoy the enemy. These chests are usually from 12 to 18 inches in length, and about 8 or 10 in breadth, having their outer or upper terminating in an edge. They are nailed to several places of the quarter-deck and bulk-head of the waist, having a train of powder which communicates with the inner apartments of the ship.

POWER, in Arithmetic and Algebra, that which arises by the successive multiplication of any number or quantity into itself, the degree of the power being always denominated by the number of equal factors that are employed; thus,

$$\begin{array}{ll} 2 = \dots\dots\dots 2^1, \text{ 1st power of 2.} \\ 2 \times 2 = \dots\dots\dots 2^2, \text{ 2d power or square.} \\ 2 \times 2 \times 2 = \dots\dots\dots 2^3, \text{ 3d power or cube.} \\ 2 \times 2 \times 2 \times 2 = \dots\dots\dots 2^4, \text{ 4th power,} \\ \quad \quad \quad \&c. \quad \quad \quad \&c. \end{array}$$

So also,

$$\begin{array}{ll} x = \dots\dots\dots x^1, \text{ 1st power.} \\ x \times x = \dots\dots\dots x^2, \text{ 2d power.} \\ x \times x \times x = \dots\dots\dots x^3, \text{ 3d power.} \\ x \times x \times x \times x = \dots\dots\dots x^4, \text{ 4th power,} \\ \quad \quad \quad \&c. \quad \quad \quad \&c. \end{array}$$

Hence it appears, that the index which denotes the degree of any power, is always equal to the number of factors from which that power arises; or one more than the number of operations. See EXPONENT and INVOLUTION.

POWER of the *Hyperbola*, is the fourth power of its conjugate axis.

POWER, in Mechanics, denotes any force, whether of a man, a horse, a spring, the wind, water, &c. which being applied to a machine tends to produce motion.

POWER is also used in Mechanics, for any of the six simple machines, viz. the lever, the balance, the screw, the wheel and axle, the wedge, and the pulley.

POWER of a *Glass*, in Optics, is by some used for the distance between the convexity and the solar focus.

POWER, in Law, is an authority which one man gives to another to act for him, and it is sometimes a reservation which a person makes in a conveyance for himself to do some acts, as to make leases or the like. 2 Lil. Abr. 339. Thus power of attorney, an instrument or deed whereby a person is authorized to act for another, either generally, or in a specific transaction.

POWER of the county, called the *Posse Comitatus*, contains the aid and attendance of all knights, gentlemen, yeomen, labourers, servants, apprentices, and all others above the age of fifteen years within the county.

POWER LOOM. See Loom, p. 596.

POZZOLANA, in Natural History, is a kind of substance formed of volcanic ashes. When mixed with a small portion of lime it quickly hardens, and this induration takes place even under water. This singular property, of becoming petrified under water, renders it peculiarly valuable as a cement, in the erection of moles, and other buildings in maritime situations.

PRACTICE, is an Arithmetical rule, principally employed in those questions in which the amount of a certain number of things is required, the price of each being given; being a more ready and expeditious method than *Compound Multiplication*, by which rule the same questions may always be resolved.

PRACTICE, is commonly divided into several cases, which by some authors are so much multiplied, as to become very burdensome to the memory, an inconvenience that more than counterbalances the advantages arising from this subdivision: in fact, the whole of the cases that are worth retaining, may be classed under the following heads:—

1. When the price is less than a penny.
2. When the price is less than a shilling.
3. When the price is less than a pound.
4. When the price is more than a pound.

And the general rule for all these cases is this:—*Rule.* Take such aliquot parts of the given number of things, as the given price is of the next superior denomination.—*Note.* In the last case, multiply first by the number of pounds; and for shillings, pence, and farthings, proceed by the above rule, and add the result to the preceding product.

Examples.

The same method may be employed in weights and measures of every description, though the rule is generally limited to money concerns.

PRÆCIPE, a writ commanding the defendant to do the thing required, or to shew cause why he hath not done it.

PRÆMUNIRE. This punishment is inflicted upon him who denies the king's supremacy the second time; upon him who affirms the authority of the pope, or refuses to take the oath of supremacy; upon such as are seditious talkers of the inheritance of the crown; and upon such as affirm that there is any obligation by any oath, covenant, or engagement whatsoever, to endeavour a change of government either in church or state, or that both or either house of parliament have or has a legislative power, without the king, &c. The judgment in præmunire at the suit of the king, against the defendant being in prison, is, that he shall be out of the king's protection; that his lands and tenements, goods and chattels, shall be forfeited to the king; and that his body shall remain in prison at the king's pleasure; but if the defendant is condemned upon his default of not appearing, whether at the suit of the king or party, the same judgment shall be given as to the being out of the king's protection and the forfeiture; but instead of the clause that the body shall remain in prison, there shall be an award of a capias. Co. Lit. 129. Upon an indictment of a præmunire, a peer of the realm shall not be tried by his peers. 12 Co. 92.

PRAGMATIC SANCTION, in the Civil Law, is defined to be a rescript, or answer of the sovereign, delivered by advice of his council, to some college, order, or body of people, upon consulting him in some case of their community. The like answer given to any particular person, is called simply rescript.

PRAM, or **PRAME**, a sort of lighter used in Holland and the ports of the Baltic sea, for loading and unloading ships.

PRATIC, or **PRATIQUE**, a term used in the European ports of the Mediterranean sea, which implies the permission to trade and communicate with the natives of any place, after having performed the required quarantine.

PRAYER, in Theology, a petition put up to God for the obtaining of some future favour.

PREBENDARY, an ecclesiastic who enjoys a prebend. The difference between a prebendary and a canon is, that the former receives his prebend in consideration of his officiating in the church; but the latter merely by his being received into the cathedral or college.

PRECEDENCE, or **PRECEDENCY**, a place of honour to which a person is entitled; this is either of courtesy or of right. The former is that which is due to age, estate, &c. which is regulated by custom and civility: the latter is settled by authority, and when broken in upon gives an action at law.

PRECEPT, in Law, a command in writing sent by a chief justice, justice of the peace, &c. for bringing a person, record, or other matter, before him.

PRECEPT, is also used for the command or incitement by which one man stirs up another man to commit felony, theft, &c.

PRECESSION of the Equinoxes, which denotes that slow and imperceptible motion by which the equinoxes change their

places, going backwards, or westward, contrary to the rest of the signs, may be thus explained. The fixed stars vary their right ascension and declination, but keep the same latitude; these variations are accounted for by supposing that the celestial sphere revolves round the pole of the ecliptic. Or, that the poles of the equator revolve round those of the ecliptic. And this revolution is called the precession of the equinoxes, because by it, the time and place of the sun's equinoctial station precedes the usual calculations. The ecliptic, the solstices, the equinoxes, and all the points of the ecliptic, are moving from Aries towards Pisces; i.e. from east to west. The equinoctial points are thence carried further back among the preceding signs or stars, at the rate of about one degree in 71 years and some few days. The annual precession is about $50'' \frac{1}{2}$; that is, if the celestial equator cuts the ecliptic in a particular point on any day of this year, it will, on the same day of the following year, cut in a point $50'' \frac{1}{2}$ to the west of its former intersection, and the sun will come to the equinox $20' 23''$ before he has completed his revolution of the heavens. Thus the equinoctial or tropical year, or true year of the seasons, is so much shorter than the revolution of the sun, or the sidereal year. The equinoctial points make a complete revolution in about 25,579 years, the equator being all the while inclined to the ecliptic in nearly the same angle. Therefore the poles of the diurnal revolution must describe a circle round the poles of the ecliptic at the distance of nearly $23\frac{1}{2}$ degrees in 25,579 years. Hence the longitude, right ascension, and declination, of every star will be variable, and consequently the pole of the equinoctial cannot always be directed to the same star. In the time of Hipparchus the equinoctial points were fixed to the first stars of Aries and Libra; and the stars which were then in conjunction with the sun when he was in the equinox, are now a whole sign to the eastward of Aries. There are obviously then two zodiacs, a zodiac of the signs, moveable round the fixed zodiac and ecliptic. The precession of the equinoxes producing an annual increase of $50'' \frac{1}{2}$ in the longitude of the fixed stars, makes exactly a degree in 71 years, 19 days, and 12 hours. Their right ascension varies from $-60'$ to $+143'$ in certain stars round the pole. The annual increase in right ascension of others has been given as low as $5'$, or about $15'$ in 180 years. Their declinations vary from $20'$ to $0'$ annually *plus* or *minus*, or in 72 years from 24 minutes to $2' 24''$ *plus* or *minus*.

Astronomers have reckoned by the fixed and intellectual zodiac from a very early period; the Egyptians and Chaldeans reckoned according to the intellectual zodiac ages before Hipparchus made his discovery of the precession of the equinoxes. The first of their signs was *Taurus*. Hipparchus was the first among the Greeks, however, who established what is called a fixed zodiac; and he placed Aries at the first of the signs. This shews that the Greeks were in the habit of copying from the Egyptians in these matters; for the ram has nothing to do with Grecian mythology; on the contrary, it was the type of the Egyptian Ammon. In the Egyptian zodiac, by the second *Hermes*, Aries is represented as a man with ram's horns. The sun in this sign was worshipped as the god Ammon. This recession of Aries from the equinoctial point, and its occupation by Pisces has furnished some learned men with curious illustrations respecting the origin of the zodiacal signs, the mythology of the Greeks, the Egyptians, and Orientalists. In 365d. 6h. 49mi. the earth revolves round the sun, and during its progress in this annual course, it passes through the 12 signs of the zodiac successively. Hence we are accustomed to say the sun is in Aries, Taurus, &c. when in fact it is the earth that is in those signs, and the sun, as viewed from the earth, appears in the opposite part of its orbit.

To find the Precession in right Ascension and Declination.—Put d = the declination of a star, and a = its right ascension; then their annual variations, or precessions, will be nearly as follows, viz.

$20'' 084 \times \cos. a$ = the annual precession in declination, and $46'' 0619 + 20'' 084 \times \sin. a \times \tan. d$ = that of right ascension. See the *Connaissance des Temps* for 1792, p. 206.

PRECIPITATE. When a body, dissolved in a fluid, is either in whole or in part made to separate and fall down in the concrete state, this falling down is called precipitation, and the matter thus separated is called a precipitate.

PREDIAL TITHES, those which are paid of things arising and growing from the ground only, as corn, hay, fruit of trees, and the like.

PREDICATE, in Logic, that part of a proposition which affirms or denies something of the subject; thus, in these propositions, snow is white, ink is not white,—whiteness is the predicate which is affirmed of snow, and denied of ink.

PREGNANCY, to be with child. This is a plea in stay of execution, when a woman is convicted of a capital crime, alleging that she is with child; in which case the judge must direct a jury of twelve discreet women to inquire of the fact; and if they bring in their verdict "quick with child," execution shall be staid generally, until either she is delivered, or proves by the course of nature not to have been with child. 4 Black. 395.

PREMISES, is that part of the beginning of a deed, the office of which is to express the grantor and grantee, and the land or thing granted.

PREROGATIVE, is a word of large extent, including all the rights and privileges which by law the king has as chief of the commonwealth, and as intrusted with the execution of the laws.

PREROGATIVE Court, the court wherein all wills are proved, and all administrations taken which belong to the archbishop by his prerogative; that is, in case where the deceased has goods of any considerable value out of the diocese wherein he died; and that value is ordinarily 5*l.* except it is otherwise by composition between the said archbishop and some other bishop, as in the diocese of London it is 10*l.*

PRESBYTERIANS, a numerous and highly respectable sect of Protestants, so called from their maintaining that the government of the church appointed in the New Testament was by Presbyteries; that is, by ministers and ruling elders, associated for its government and discipline.

PRESENTATION, in Law, the act of a patron offering his clerk to be instituted in a benefice of his gift, the same being void.

PRESENTMENT OF OFFENCES, is that which the grand jury find to their own knowledge, and present to the court without any bill of indictment laid before them at the suit of the king; as, a presentment of a nuisance, a libel, and the like, upon which the officer of the court must afterwards frame an edictment before the party presented can be put to answer it. There are also presentments by justices of the peace, constables, surveyors of the highways, church-wardens, &c.

PRESIDENT, an officer created or elected to preside over a company, in contradistinction to the other members, who are called residents.

PRESS, a machine of wood or iron serving to squeeze any body very close. Presses usually consist of six pieces: two flat smooth planks, between which the things to be pressed are laid; two screws or worms fastened to the lower plank, and passing through two holes in the upper; and two nuts in the form of an S, that serve to drive the upper plank, which is moveable, against the lower, which is fixed. See **BRAMAH'S MACHINE**.

PRESSES used for expressing Liquors, are in most respects the same with the common presses, only the under plank is perforated with a great number of holes, for the juice to run through. Others have only one screw or arbor passing through the middle of the moveable plank, which descends into a kind of square box full of holes, through which the juices flow as the arbor is turned.

PRESS used by Joiners, to keep close the pannels, &c. of wainscot, consists of two screws and two pieces of wood, four or five inches square, and two or three feet long, whereof the holes at two ends serve for nuts to the screws.

Founders' PRESS, is a strong square frame consisting of four pieces of wood firmly joined together with tenons, &c. It is of various sizes; two of them are required to each mould, at the two extremes whereof they are placed: so as that, by driving wooden wedges between the mould and sides of the press, the two parts of the mould for the metal may be pressed close together.

PRESS, Binder's Cutting, is a machine used equally by book-binders, stationers, and pasteboard-makers; consisting of two large pieces of wood in form of cheeks, connected by two strong wooden screws; which, being turned by an iron bar

draw together or set asunder the cheeks, as much as is necessary for the putting in the books or paper to be cut. The cheeks are placed lengthwise on a wooden stand in form a chest, into which the cuttings fall. Aside of the cheeks are two pieces of wood of the same length with the screws, serving to direct the cheeks, and prevent their opening unequally. Upon the cheeks the plough moves, to which the cutting knife is fastened by a screw; which has its key to dismount it, on occasion, to be sharpened. The plough consists of several parts; among the rest a wooden screw or worm, which catching within the nuts of the two feet that sustain it on the cheeks, brings the knife to the book or paper which is fastened in the press between two boards. This screw, which is pretty long, has two directories, which resemble those of the screws of the press. To make the plough slide square and even on the cheeks, so that the knife may make an equal paring, that foot of the plough where the knife is not fixed slides in a kind of groove, fastened along one of the cheeks. Lastly, the knife is a piece of steel, six or seven inches long, flat, thin, and sharp, terminating at one end in a point, like that of a sword, and at the other in a square form, which serves to fasten it to the plough. As the long knives used by us in the cutting of books or papers are apt to jump in the cutting thick books, the Dutch are said to use circular knives with an edge all round; which not only cut more steadily, but last longer without grinding.

Press, Packing. A very ingenious and useful packing press, invented by Mr. John Peck, procured for him in 1798, a reward from the Society of Arts. This machine consists of two very strong horizontal beams, one at the bottom for the bed, and the other at the top of the press. These are united by two iron screws, which stand in a vertical position, and therefore serve as cheeks to the press. The follower of this press is a very strong horizontal beam, having two nuts fitted into it at its ends. These nuts act upon the threads of the two vertical screws, and therefore it is plain, when they are turned round, that the follower will rise and fall accordingly. The nuts are so fitted into the follower, as to admit of a circular motion round the screw, but are not permitted to rise or fall without the follower. To give them motion, the edges of the circular rings are cut into cogs or teeth, and are turned by means of an endless screw for each, situated at the opposite ends of the horizontal spindle, which revolves in bearings attached to the follower of the press. The spindle has a winch at each end, by turning which the two endless screws act upon the whole or teeth of the nuts, and by thus causing them to turn round with equal velocities, raises or depresses the follower always parallel to itself, and also to the head and bottom bed. The great utility of this press consists in its being capable of packing two sets of bales at once, thus answering the purpose of two presses, with more expedition, and less room. It is placed on the floor of the warehouse, and behind it a stage is erected, just half the height of the whole press. One set of bales is then made up on the floor, and the other upon the stage. Suppose the follower raised up above the level of the stage, a bale of goods is then placed on the lower bed, and by turning the winches the follower is forced down upon it, and remains there till it is sufficiently pressed. While the men are tying up this bale below, others on the stage are loading the follower, and the winches being turned, the former bale is released, and the latter receives the pressure. By these means, no time is lost in screwing up or opening the press, since it performs work in both ways.—The Philosophical Transactions for 1781, contains an account of a double screw applied to a press by Mr. W. Hunter. Its power is considerable, but a minute description will occupy too much of our room.

Press, Copperplate Printing. In addition to the presses already noticed, although many others, adapted to particular purposes, are in use, the copperplate printing press demands a distinct description. This machine, of which a representation is given in the following figure, consists, like the common printing presses, (for which see **PRINTING**.) of a body and a carriage.

The body consists of two cheeks, P P, of different dimensions, ordinarily about four feet and a half high, a foot thick, and two and a half apart, joined at top and bottom by cross pieces. The cheeks are placed perpendicularly on a wooden

stand or foot, L M, horizontally placed, and sustaining the whole press. From the foot likewise rise four other perpendicular pieces, c, c, c, c, joined by other cross or horizontal ones, d, d, d, which may be considered as the carriage of the press, as serving to sustain a smooth, even plank, H I K, about 4½ feet long, 2½ feet broad, and 1½ inch thick; upon which the engraven plate is to be placed. Into the cheeks go two wooden cylinders or rollers D E, F G, about six inches in diameter, borne up at each end by the cheeks, whose ends, which are lessened to about two inches diameter, and called *trunnions*, turn in the cheeks between two pieces of wood, in form of half moons, lined with polished iron, to facilitate the motion. The space in the half moons, left vacant by the trunnion, is filled with paper, pasteboard, &c. that they may be raised and lowered at discretion; so as only to leave the space between them necessary for the passage of the plank charged with the plate,

paper, and blankets. Lastly, to one of the trunnions of the upper roller is fastened a cross, consisting of two levers A B, or pieces of wood, traversing each other. The arms of this serve in lieu of the handle of the common press, giving a motion to the upper roller, and that to the under one; by which means the plank is protruded, or passed between them.

The practice of printing from copper-plates is nearly as follows:—The workmen take a small quantity of the ink on a rubber made of woollen rags, strongly bound about each other, and with this smear the whole face of the plate as it lies on a grate heated by a charcoal fire, or steam. The plate being sufficiently inked, they first wipe it over with a foul rag, then with a cleaner one, and lastly with the palm of their left and right hand, and to dry the hand and forward the wiping, they rub it from time to time on whiting. The address of the workman consists in wiping the plate perfectly clean, without taking the ink out of the engraving. The plate thus prepared is laid on the plank of the press; over the plate is laid on the paper, first well-moistened to receive the impression; and over the paper two or three folds of flannel. Things being thus disposed, the arms of the cross are pulled, and by that means the plate, with its furniture, is passed through between the rollers, which pinching very strongly, yet equally, presses the moistened paper into the strokes of the engraving, whence it takes out the ink; and receives the engraved impression.

Perkins' Copperplate Presses.—The press for which this celebrated engineer and artist has obtained a patent, differs not in principle from that already described, although it varies considerably in several particulars. The levers or spokes, instead of extending from the pinion of the roller to the hand of the pressman, terminate in an iron circumference, which forms a wheel, on the outer surface of which numerous handles are inserted, resembling those fixed in the wheels by which ships are steered. By these means, when the wheel is put in motion, the momentum obtained, renders the resistance which the roller receives while passing over the plate almost imperceptible. The roller, having a section cut off longitudinally, performs its work with the circular part only, on which account the limits of the impression must always be determined by the extent of

its convexity. Unless, therefore, the roller be made very large, this press is better adapted for small plates than large ones. The plate having received its ink and paper, is presented to the roller, which, by turning the wheel, begins its work at the commencement of its convex surface, and passes on until the flat part turns downward. At this instant the impression ceases, the blanket which had been drawn in between the paper on the plate, and the roller, regains its original state of tension, the plate is released, and returns on its carriage to the workman, delivering up its paper, and is ready to be charged for another impression. It must be obvious from hence, that the paper never receives from the press a double impression, but is taken off like proof prints in the common way.

PRESS OF SAIL, signifies as much sail as the then state of the wind, &c. will permit a ship to carry.

PRESSED-MAN, one who has been impressed into the king's service, in contradistinction to a volunteer.

PRESS-GANG, a detachment of seamen, who (under the command of a lieutenant) are empowered, in time of war, to take any seafaring men, and oblige them to serve on board the king's ships.

PRESSING, in the Manufactures, is the violently squeezing a cloth, stuff, &c. to render it glossy.

PRESSURE ENGINES, for raising water by the pressure and descent of a column enclosed in a pipe, have been lately erected in different parts of this country. The principle now adverted to, was adopted in some machinery constructed in France about 1731, (see *Belidor de Arch. Hydraul.* lib. 4. ch. 1.) and was likewise adopted in Cornwall about fifty years ago. But the pressure-engine, of which we are about to give a particular description, is the invention of Mr. R. Trevithick, who probably was not aware that any thing at all similar had been attempted before. This engine, a section of which, on a scale of a quarter of an inch to a foot, as shewn in the annexed

figure, was erected a few years ago at the Druid Copper Mine, in the parish of Illogan, near Truro. A B represents a pipe six inches in diameter, through which water descends from the head to the place of its delivery, to run off by an adit at S, through a fall of 34 fathoms in the whole; that is to say, in a close pipe, down the slope of a hill 200 fathoms long, with 26 fathoms fall; then perpendicularly six fathoms, till it arrives at B, and thence through the engine from B to S two fathoms. At the turn B the water enters into a chamber C, the lower part of which terminates in two brass cylinders, four inches in diameter; in which two plugs, or pistons of lead, D and E, are capable of moving

up and down by their piston rods, which pass through a close packing above, and are attached to the extremities of a chain leading over, and properly attached to the wheel Q, so that it cannot slip.

The leaden pieces D and E are cast in their places, and have no packing whatever. They move very easily; and if at any time they should become loose, they may be spread out by a few blows with a proper instrument, without taking them out of their place. On the sides of the two brass cylinders, in which D and E move, there are square holes communicating towards F and G, which is a horizontal trunk or square pipe, four

inches wide and three inches deep. All the other pipes G, G, and R, are six inches in diameter, except the principal cylinder wherein the piston H moves; and this cylinder is ten inches in diameter, and admits a nine-foot stroke, though it is here delineated as if the stroke were only three feet.

The piston rod works through a stuffing-box above, and is attached to M N, which is the pit rod, or a perpendicular piece divided into two, so as to allow its alternate motion up and down, and leave a space between, without touching the fixed apparatus, or great cylinder. The pit rod is prolonged down into the mine, where it is employed to work the pumps, or if the engine were applied to millwork, or any other use, this rod would form the communication of the first mover. K L is a tumbler, or tumbling-bob, capable of being moved on the gudgeons V, from its present position to another, in which the weight L shall hang over with the same inclination on the opposite side of the perpendicular, and consequently the end K will then be as much elevated as it is now depressed. The pipe R S has its lower end immersed in a cistern, by which means it delivers its water without the possibility of the external air introducing itself; so that it constitutes a torricellian column, or water barometer, and renders the whole column from A to S effectual; as we shall see in our view of the operation.

The Operation.—Let us suppose the lower bar K V of the tumbler to be horizontal, and the rod P O so situated, as that the plugs or leaden pistons D and E shall lie opposite to each other, and stop the waterways C and F. In this state of the engine, though each of these pistons is pressed by a force equivalent to more than a thousand pounds, they will remain motionless, because these actions being contrary to each other, they are constantly in equilibrio. The great piston H being here shown, as at the bottom of its cylinder, the tumbler is to be thrown by hand into the position here delineated. Its action upon O P, and consequently upon the wheel Q, draws up the plug D, and depresses E, so that the water-way G becomes open from A B, and that of F to the pipe R; the water consequently descends from A to C; thence to G G G, until it acts beneath the piston H. This pressure raises the piston, and if there be any water above the piston, it causes it to rise and pass through F into R. During the rise of the piston (which carries the pit rod M N along with it,) a sliding block of wood I, fixed to this rod, is brought into contact with the tail K of the tumbler, and raises it to the horizontal position, beyond which it oversets by the acquired motion of the weight L.

The mere rise of the piston, if there were no additional motion in the tumbler, would only bring the two plugs D and E to the position of rest, namely, to close G and F, and then the engine would stop; but the fall of the tumbler carries the plug D downwards quite clear of the hole F, and the other plug E upwards, quite clear of the hole G. These motions require no consumption of power, because the plugs are in equilibrio, as was just observed. In this new situation, the column A B no longer communicates with G, but acts through F upon the upper part of the piston H, and depresses it; while the contents of the great cylinder beneath that piston are driven out through G G G, and pass through the opening at E into R. It may be observed, that the column which acts against the piston is assisted by the pressure of the atmosphere, rendered active by the column of water hanging in R, to which that assisting pressure is equivalent, as has already been noticed.

When the piston has descended through a certain length, the alide or block at T, upon the piston rod, applies against the tail K of the tumbler, which it depresses, and again oversets; producing once more the position of the plugs D E, here delineated, and the consequent ascent of the great piston H, as before described. The ascent produces its former effect on the tumbler and plugs; and in this manner it is evident, that the alterations will go on without limit; or until the manager shall think fit to place the tumbler and plugs D E in the positions of rest; namely, so as to stop the passages F and G. The length of the stroke may be varied by altering the position of the pieces T and I, which will shorten the stroke the nearer they are together; as in that case, they will sooner alternate upon the tail K. As the sudden stoppage of the descent of the column A B, at the instant when the two plugs were both in the waterway, might jar and shake the apparatus, these plugs are

made half an inch shorter than the depth of the side holes; so that in that case, the water can escape directly through both the small cylinders to it. This gives a moment of time for the generation of the contrary motion in the piston and the water in G G G, and greatly deadens the concussion, which might else be produced.

Some former attempts to make pressure engines upon the principle of the steam-engine, have failed; because water, not being elastic, could not be made to carry the piston onwards a little, so as completely to shut one set of valves and open another. In the present judicious construction, the tumbler performs the office of the expansive force of steam at the end of the stroke.

Mr. Boswell suggests, as a considerable improvement, that the action of this engine should be made elastic by the addition of an air-chamber, on the same principle as that used in fire-engines; this, he thinks, might be best effected by making the piston hollow, with a small orifice in the bottom, and of a larger size, to serve for this purpose, as the spring of the air would then act both on the upward and downward pressure of the water.

PRESSURE, in Physics, is properly the action of a body, which makes a continual effort or endeavour to move another body on which it rests; such as the action of a heavy body supported by a horizontal table, and is thus distinguished from percussion or momentary force of action. Since action and reaction are equal and contrary, it is obvious that pressure equally relates to both bodies, viz. the one which presses, and that which receives the pressure. See a few remarks on the difference between percussion and pressure, under the article PERCUSSION.

PRESSURE of Fluids, is of two kinds, viz. of elastic and non-elastic fluids.

PRESSURE of Non-elastic Fluids. The upper surface of a homogeneous heavy fluid in any vessel, or any system of communicating vessels, is horizontal.

Fig. 1.

This is a matter of universal experience; and, as it is easily observed, may be taken for the distinguishing property of fluids. Thus, if A B C D E F, fig. 1, be a vessel in which the branches C D H, E F G, have a free communication with the part A B; then if water, or mercury, or wine, or any other fluid commonly reckoned non-elastic, be poured in either at A, C, or E, and when the whole is at rest, the surface of the fluid

stands at I K in the larger trunk; if the line L I K M be drawn parallel to the horizon, the surface of the fluid will stand at L in the branch E F, and at M in the branch C D; and this whatever are the inclinations of those branches, or the angles at F and D, G and H.

This is usually explained by saying, that since the parts of a fluid are easily moveable in any direction, the higher particles will descend, by reason of their superior gravity, and raise the lower parts till the whole comes to rest in a horizontal plane. Now, what is called the horizontal plane is, in fact, a portion of a spherical surface, whose centre is the centre of the earth: hence it will follow, that if a fluid gravitate towards any centre, it will dispose itself into a spherical figure, the centre of which is the centre of force.

Prop. If a fluid, considered without weight, is contained in any vessel whatever, and, an orifice being made in the vessel, any pressure whatever be applied thereto, that pressure will be distributed equally in all directions.

Through any point N, fig. 1, taken at pleasure below the surface of the fluid L I K M, imagine the horizontal plane P N O Q

to pass. It is obvious, the weight of the fluid contained in the vessel below P N O Q, contributes nothing to the support of the columns L P, I O, M Q, so that the equilibrium would obtain in like manner, if the fluid contained in that part of the vessel below P N O Q had lost its weight entirely. We may, therefore regard this fluid as being solely a mean of communication between the columns L P, I O, M Q; in such manner that it will transmit the pressure resulting from the columns L P, M Q, to the column I O, and reciprocally. If now, instead of the columns L P, I O, M Q, of the fluid, pistons were applied to the surfaces P, N, O, and Q, and were separately urged by pressures respectively equal to the pressures of the columns L P, I O, M Q, the equilibrium would manifestly obtain in like manner. Or if a pressure, equal that of the column M Q, be applied at Q, while the columns L P, I O, remain, the equilibrium will still obtain; and this, whatever are the directions of the several branches, and their sinuosities at D, F, &c. whence the proposition is evident.

Cor. 1. Not only is the pressure transmitted equally in all directions, but it acts perpendicularly upon every point of the surface of the vessel which contains the fluid.

For, if the pressure which acts upon the surface were not exerted perpendicularly, it is easy to see that it could not be entirely annihilated by the reaction of that surface; the surplus force would, therefore, occasion fresh action upon the particles of the fluid, which must be transmitted in all directions, and occasion a motion in the fluid; that is, the fluid could not be at rest in the vessel, which is contrary to experience.

Cor. 2. Hence also, if the parts of a fluid, contained in any vessel A B C D, open towards the part A B, are solicited by any forces whatever, and remain, notwithstanding, in equilibrium, these forces must be perpendicular to the surface A B. For the equilibrium would obtain, if a cover or a piston of the same figure as the surface A B, were applied to it; and it is manifest, that in this case, the forces which act at the surface, or their resultant, must be perpendicular to that surface.

Cor. 3. If, therefore, the forces which act upon the particles of the fluid are those of gravity, the direction of gravity is perpendicular to the surface of a tranquil fluid; consequently, the surface of a heavy fluid, to be in equilibrium, must be horizontal, whatever may be the figure of the vessel in which it is contained.

Cor. 4. If a vessel, as A B C D, closed throughout, except a small orifice O, is full of a fluid, without weight, then if any pressure be applied at O, the resulting pressure on the plane surface or bottom C D, will neither depend upon the quantity of fluid in the vessel, nor on its shape; but since the pressure applied at O, is transmitted equally in all directions, the actual pressure upon C D will be to the pressure at O, as the area of C D is to that of the orifice.

Cor. 5. In the same manner will the pressure applied at O be exerted in raising the top A B of the vessel; so that if the top be a plane, of which O forms a part, the vertical pressure tending to force A B upwards, will be to the force applied at O, as the surface A B to the area O. See *HYDROSTATIC BELLows*.

PROP. The pressure of a fluid on the horizontal base of a vessel in which it is contained, is as the base and perpendicular altitude, whatever be the figure of the vessel that contains it; the upper surface of the fluid being supposed horizontal.

Let any horizontal plane, G H, be supposed drawn, and conceive the fluid contained in the part G C D H of the vessel to be void of weight; then, as it is evident, from cor. 3 of the foregoing proposition, that any vertical filament whatever, E I of the heavy fluid A B H G, exerts at the point I a pressure,

which is distributed equally through the fluid G C D H; and that this pressure acts equally upwards to oppose the action of each of the other filaments which stand vertically above G H; therefore, the filament E I alone keeps in equilibrio all the other filaments of the mass A B H G; consequently, the mass G C D H being still supposed without weight, there will not result any other pressure on the bottom C D than that of a single filament E I; which, being transmitted equally to all the points of C D, will make the pressure upon C D to that upon the base I of the filament E I, as the area of C D to the area I. If, therefore, we imagine a heavy fluid contained in A C D B, to be divided into horizontal laminæ, the upper lamina will communicate to the bottom C D, no other action than would be communicated by the single filament a b; and the same thing obtaining with respect to each lamina, the bottom therefore is pressed in the same degree as it would be by the combined operation of the filaments a b, b c, c d, &c. Whence, as this pressure is transmitted equally to all points of C D, it will be equal to the product of C D into the sum of the pressures which the filaments a b, b c, c d, are capable of exercising on the same point, or it will be proportional to C K \times (a b + b c + c d +, &c.).—*Gregory's Mechanics*, article 384, &c.

Centre of Pressure. See *CENTRE*.

PREVARICATION, in the Civil Law, is where the informer colludes with the defendants, and so makes only a sham prosecution.

PREVENTER, in naval language, an additional rope employed at times to support any other, when the latter suffers an unusual strain, particularly in a strong gale of wind. *Preventer-brace*, a temporary brace, fixed occasionally to succour the main or fore yard, or to supply the place of the usual braces, in the event of their being shot away in action. *Preventer-stay*, is a smaller stay, fixed above the standing one, and serves to relieve the latter, or to supply its place. *Preventer-shrouds*, are applied to serve the same purposes.

PRICE, DR. RICHARD, a celebrated English mathematician, fellow of the Royal Society, and of the Academy of Sciences, New England, was born at Tynton, in Glamorganshire, in 1723, and died in London, in 1791, in his sixty-eighth year.

PRICK, in seafaring language, is a term applied to a roll of small rope, &c. as a prick of spun yarn, a prick of tobacco.

PRICKING, in the sea language, is to make a point on the plan or chart, near about where the ship then is, or is to be at such a time, in order to find the course they are to steer.

PRICKING a Chart, the act of tracing a ship's course upon a marine chart, by the help of a scale and compasses, so as to discover her present situation. *Pricking a Sail*, is the running a middle seam between the two seams which unite every cloth of a sail to the next adjoining, and is rarely performed till the sails have been worn some time.

PRIMÆVIÆ, among Physicians, denote the whole alimentary duct; including the œsophagus, stomach, and intestines, with their appendages.

PRIMARY ROCKS, are so called by the Wernerians, because therein no organic remains have been found, hence it is supposed they were formed prior to the creation of animals or vegetables. They are extremely hard, and their substances are pure crystallized matter, in large vertical masses, more or less inclined to the horizon, and without fragments, or other rocks. They form the lowest part of the earth's surface with which we are acquainted; and not only constitute the foundation on which the other rocks rest, but in many situations pierce through the incumbent rocks and strata, and form the highest mountains in alpine districts.

PRIMARY Planets, are such as revolve about the sun as a centre; such are Mercury, Venus, Terra the Earth, Mars, Vesta, Juno, Pallas, Ceres, Jupiter, Saturn, and Uranus or the Georgium Sidus; being thus called in contradistinction to the secondary planets or satellites, which revolve about their respective primaries. See *PLANET*.

PRIMALTES, in Natural History, the first order of mammalia in the Linnæan system. The animals in this order are far-

nished with fore-teeth or cutting-teeth: the four above are parallel; two breasts on the chests. There are four genera, viz. Homo, Lemur, Simia, Vespertilio.

PRIMING, or **PRIME** of a **GUN**, is the gunpowder put into the pan or touch-hole of a piece to give it fire thereby; and this is the last thing done in charging. For pieces of ordnance they have a pointed iron rod, to pierce the cartridge through the touch-hole, called primer or priming-iron.

PRIME NUMBERS, are those which have no divisors, or which cannot be divided into any number of equal integral parts, less than the number of units of which they are composed; such as 2, 3, 5, 7, 11, 13, 17, &c. These numbers have formed a subject of investigation and inquiry from the earliest date down to the present day; and a rule for finding them is still amongst the desiderata of mathematicians. The method of finding a prime number beyond a certain limit, by a direct process, is considered one of the most difficult problems in the theory of numbers; which, like the quadrature of the circle, the trisection of an angle, and the duplication of the cube, have engaged the attention of many able mathematicians, but without arriving at any satisfactory result.

PRIME Vertical, is that vertical circle, or azimuth, which is perpendicular to the meridian, and passes through the east and west points of the horizon.

PRIME Verticals, in Dialling, or **PRIME Vertical Dials**, are those that are projected on the plane of the prime vertical circle, or on a plane parallel to it. These are otherwise called direct, erect, north, or south dials.

PRIME of the Moon, is the new moon at her first appearance, for about three days after her change. It means also the **GOLDEN NUMBER**, which see.

PRIMULA OFFICINALIS. (*The Cowslip*.) The flowers appear in April; they have a pleasant sweet smell, and a sub-acrid, bitterish, substringent taste. An infusion of them, used as tea, is recommended as a mild corroborant in nervous complaints. A strong infusion of them, with a proper quantity of sugar, forms an agreeable syrup, which for a long time maintained a place in the shops. By boiling, even for a little time, their fine flavour is destroyed. A wine is also made of the flowers, which is given as an opiate.

PRIMUM MOBILE, in the Ptolemaic Astronomy, the ninth or highest sphere of the heavens, whose centre is that of the world, and in comparison of which the earth is but a point. This the ancients supposed to contain all other spheres within it, and to give motion to them, turning itself, and all of them, quite round in twenty-four hours.

PRINCE, a person invested with the supreme command of a state.

PRINCE's Metal, a mixture of copper and zinc, in imitation of gold.

PRINCIPAL, in Arithmetic or in Commerce, is the sum lent upon interest, either simple or compound. See **INTEREST**.

PRINCIPAL and **Accessory**, in Criminal Law, principal is the person who himself commits the offence. An accessory is a person who participates by advice, command, or concealment. There are two kinds of accessories; before the fact, and after it. The first is he who commands or procures another to commit felony, and is not present himself; for if he be present, he is a principal. The second is he who receives, assists, or comforts any man that has done murder or felony, whereof he has knowledge. A man may be accessory to an accessory, by aiding, receiving, &c. an accessory in felony. An accessory in felony before the fact, shall have judgment of life and member, as well as the principal who did the felony: but not till the principal be first attainted, and convicted or outlawed thereon. Where the principal is pardoned without attainder, the accessory cannot be arraigned; it being a maxim in law, *Ubi non est principalis, non potest esse accessorius*. But if the principal be pardoned, or have his clergy after attainder, the accessory shall be arraigned. 4 and 5 W. and M. cap 4; and by stat. 1 Anne, cap. 9, it is enacted, that where the principal is convicted of felony, or stands mute or challenges above twenty of the jury, it shall be lawful to proceed against the accessory in the same manner as if the principal had been attainted; and notwithstanding such principal shall be admitted to his clergy, pardoned or delivered before attainder. In some cases also,

if the principal cannot be taken, then the accessory may be prosecuted for a misdemeanor, and punished by fine, imprisonment, &c. stat. ib. see stat. 5 Anne, cap. 31. In the lowest and highest offences there are no accessories, but all principals: as in riots, routs, forcible entries, and other trespasses, which are the lowest offences. So also in the highest offence, which is according to our law high treason, there are no accessories.—Coke.

PRINGLE, SIR JOHN, a very distinguished physician and philosopher, was born in Roxburghshire in 1707, and took his degree of M.D. at Leyden in 1730; and there published his "*Dissertatio de Marcere Senili*," in 4to. In 1766 he was elected President of the Royal Society, an honour which he resigned in 1778, and died in 1782.

PRINT, the impression taken from a copper-plate.

PRINTING, in its general signification, is the art of taking impressions from characters or figures, moveable or immovable, on paper, vellum, linen, silk, &c.. Of printing, there are four kinds; one, from plates of copper or steel for pictures, (see *Copperplate Printing*); another, from blocks, in which birds, flowers, &c. are cut for linen, (see *Calico Printing*); a third, from solid metal pages, cast for the printing of books, (see *Stereotype*); and finally, as of more importance than either, from moveable letters, to which the world is so much indebted for the treasures of literature with which it is enriched.

It is somewhat remarkable, that while the art of **LETTERPRESS PRINTING** has formed a new era in the history and character of man, the origin of its invention is involved in mysterious obscurity. The primitive honour of having given birth to this sublime vehicle of knowledge, has been claimed by Meun, Strasburg, Harlem, Dordrecht, Venice, Rome, Florence, Basle, and Augsburg. Harlem, Mentz, and Strasburg are, however, the only places that can advance formidable reasons in favour of their respective claims; but the decision of this much disputed question lies not within the province of this work.

It is admitted by all parties, that this important invention took place about the year 1440, and was brought to England by William Caxton, who set up his first press in Westminster Abbey, and began to print books soon after the year 1471. Since that period, considerable improvements have been made in various branches of the art, but more particularly so in the construction of presses, the increase and application of power, the diminution of manual labour, and the facilities given to expedition.

In the early days of printing, the presses were invariably made of wood, and in general construction bore a strong resemblance to those now in use. The representation of one bearing the date of 1560, is now before us, and its appearance is not essentially different from the improved wood press, in the annexed figure, which we proceed to describe. See the *Plate Printing Presses*.

The body of the press, fig. 1, consists of two strong posts, *h*, called the cheeks, placed perpendicular, and joined together by four horizontal cross pieces; the upper of these, *a*, is called the cap, and has no office but to retain the two cheeks at their required distances, and support the heads; the next cross piece, *c*, is called the head; it is fitted by tenons at the ends into mortises between the cheeks, and these mortises are filled up with pieces of pasteboard or soft wood, in such a manner as to admit of a small motion or yielding. The head is sustained by two long screw-bolts, which suspend it from the cap: in the head is fixed a brass nut, containing a female screw or worm, which is fastened in the wood by two short bolts to keep it up: the worm is adapted to receive the screw by which the pressure is produced. The third cross piece, *e*, called the shelves, or till, is to guide and keep steady a part, *i*, called the hose, in which the spindle of the screw (to be spoken of hereafter) is enclosed. The fourth cross plank, *f*, called the winter, is fitted between the cheeks to bear the carriage; it sustains the effort of the press beneath, as the head does above, each giving way a little, the one upwards, the other downwards, to make the pull the easier. The spindle, *g*, is an upright piece of iron, pointed at the lower end with steel, having a male screw formed on its upper end, which enters about four inches into the female screw or worm fixed in the head: through the eye of this spindle is fixed the bar or handle, *k*, by which the pressman works the

press. The platen, *k*, or surface which acts upon the paper to produce the impression, is suspended from the point of the spindle by means of a square block or frame of wood, *i*, called the hose, which is guided by passing through the shelves, *e*: the lower part of the spindle passes through the hose, and its point rests upon the platen *k*, being received into the plug fixed in a brass pan supplied with oil, which pan is fixed to an iron plate let into the top of the platen *k*. The pressman then, by pulling the bar *h*, fixed in the eye of the spindle *g* by an iron key, turns the spindle, and by means of its screw presses down the platen upon the form of types, which is covered with the paper, tympan, and its blankets, all these parts being brought under the platen by the carriage, when the impression is to be given. That the platen may be suspended from the spindle, and rise up again with it, the hose, *i*, is attached to the spindle by the garter; this is a fillet of iron screwed to the hose, and entering into a nick or groove formed round the upper part of the spindle; it prevents the hose falling down on the spindle. At each corner of the lower part of the hose there is an iron hook fastened, and from these to similar hooks, fastened at each corner of the platen *k*, cords or packthread are looped to suspend the platen, and they are exactly adjusted, to hang the platen truly level.

The carriage *l*, which is the other principal part of the press, is adapted to run into the space between the cheeks under the platen. It is supported upon the ribs *n*, which are part of a horizontal wooden frame, having its fore-part supported by a wooden prop *m*, called the fore-stay, while the other end rests on the winter. On the rails of this frame two long iron bars or ribs are nailed, and under the plank of the carriage are nailed short pieces of iron or steel, called cramp irons, which slide upon the ribs, when the carriage is run in or out, by the following means. Beneath the carriage is placed a small spindle called the spit, with a double wheel formed in the middle of it, round which leather girths are passed and fastened, the opposite ends being nailed to each end of the plank *l* of the carriage. On the extreme end of the spit is fixed the handle or rounce by which the pressman turns the spit, and this, by means of the wheel and straps, runs the carriage in or out at pleasure. The carriage itself consists of a strong wooden plank *l*, upon which a square frame of wood is fixed, to form the coffin or cell, in which a marble or polished stone is enclosed, for the form of the types to be laid upon. To this coffin are fastened leather stay-girths, one to each end, which being at the opposite ends fastened to the horizontal frame, prevent the carriage running too far out, when drawn from under the platen. On the fore-part of the plank is a gallows *r*, which serves to sustain the tympan, when turned up from off the form, on their hinges. The tympan, *s*, are square frames covered with parchment. The frames are made of three slips of very thin wood, and at the top a slip of iron, still thinner, called a head-band. The two tympan, *s*, are fitted together by the frame of one being small enough to lie within the other: the outward tympan is fastened with iron hinges to the coffin. Between the two parchments of the tympan one or two thicknesses of blankets are placed, which serve to make the impression of the platen upon the surface of the letters more equal, as also to prevent the letters from being broken by the force of the press. The use of the inner tympan is, to confine these blankets. The frisket *t*, is a square frame of iron, made very thin, also covered with paper or parchment, and fastened to the head-band of the outer tympan by hinges: it folds down upon the tympan, to enclose the sheet of paper between them, the parchment or paper with which the frisket is covered being cut out in the necessary places, that the sheet, when placed between the tympan and frisket, and both together folded down on the form, may receive the ink from the types in the pages; but the frisket sheet keeps the margins clean. The tympan and frisket, when folded down, lie flat upon the form, and the carriage with them is run into the press; but when the sheet is to be taken out, the tympan is lifted up upon its hinges, and rests as represented, in an inclined position against the gallows *r*, before mentioned, at the back part of the carriage; then the frisket *t* is lifted up on its hinges, and sustained by a slip of wood *w*, hanging from the ceiling, whilst it continues open, to take out the printed sheets and put in others.

Hd.

To regulate the margin, and make the lines and pages answer each other when printed on the opposite side of the sheet, two iron points are fixed to the middle of the wooden sides of the frame of the tympan, which make two holes in the sheet. These holes are placed on the same pins, when the sheet is returned for making an impression on the other side, which is called the reiteration, and the pins are adjustable, that they may make the impressions of the opposite sides exactly correspond.

The ink, when the improved inking cylinder is not employed, is applied upon the form by balls, which are a kind of wooden cups with handles, the cavities of which are filled with wool, or hair, covered with prepared sheep's skin nailed to the wood. One of these the pressman takes in each hand, and applying them on the ink-block *v*, to charge them with ink, he works them one against the other, to mix and distribute the ink equally; and, at last, inks over the form, by beating or dabbing them several times over the whole face of it; this leaves the form in a condition to be passed under the press, with the moistened paper laid on it.

The taste for elegant typography, and the increased demand for books of every description, which followed the rapid extension of arts, sciences, and literature, throughout Europe, soon rendered an improvement on the printing press a desideratum. It was found that the common press was deficient in the necessary power to produce a sharp and beautiful impression from the types. Besides this deficiency of power, which rendered the pressmen's operations very laborious, another was, that only the half of the sheet could be printed at a time. Among the first attempts to remedy these defects, was an improvement made in France. It consisted of a wooden press of the common construction, having a platen formed of iron, instead of wood, and made sufficiently large to print the whole side of a sheet of paper at once. The under surface of this plate was covered with brass. The screw, or spindle, instead of being turned by the bar, or lever, in the usual manner, was connected by rods, with a strong lever placed at the side of the press, and was worked by the application of both hands to the lever to bring it down nearly in the same way as when working the lever of a common pump. Though additional power was then procured, the exertion required from the pressmen was too great, to bring this press into general use. A patent was taken out in the year 1796, by Mr. Prosser, of London, for an improvement in the printing press, which consisted chiefly in a mode of increasing the power, by the addition of a spring between the cap and head, to resist the pressure upwards, and a similar one under the lower board or winter, to resist the pressure downwards.

Another improvement adapted to the common press, was made by Mr. Roworth, a printer in London, and was found to be successful in practice. For the screw, he substituted a plain vertical spindle, furnished with a bar, hose, &c. as in the common press; but the upper part, where the thread of the screw is usually cut, was a plain cylinder, fitted into a socket in the head of the press. Upon the upper end of the spindle, just beneath the head, a short cross arm is fixed, which acts against a circular inclined plane, fixed under the head of the press. When the bar or lever is turned, this short arm, acting on the inclined plane, causes the spindle to descend in the same manner as the screw; but with this advantage, that the inclined plane is formed so as to give a rapid descent to the spindle when the action first begins; and when the platen comes in contact with the tympan and types, and the pressure is begun, the plane has a very slight inclination, and a power which increases as the resistance increases.

Mr. Brown of London, in 1807, took out a patent for improvements in the construction of a press, &c. part of which may be applied to presses now in common use. His press was made of iron, and the pressure produced by a screw, which was put in action by a bevel wheel and pinion. The handle which put these parts in motion, was fixed on a spindle or shaft, attached to the side of the press.

The most successful improvement on the printing press was made about this time by the late Earl Stanhope, whose genius for mechanics led him to turn his attention to this important machine. The Stanhope press is formed of iron, and prints the

whole side of a sheet of paper at once. The most important part of the invention consists in having obtained, by a combination of levers, the requisite degree of pressure without the excessive labour of the common press, where the lever or bar is fixed on the axis of the screw. A short lever is applied upon the top of the screw, and is connected by a link with the extremity of another lever, which is fixed upon the top of a spindle or axis placed parallel to the screw. To the lower end of this spindle, the handle or lever for working the press is attached; and the relative position of the levers is such, that when the pressman first pulls the handle towards him, the platen is moved or brought down with a considerable velocity; but when it arrives at the position where the pressure is required, the levers have changed their position in such a manner as to operate upon the platen with a very slow motion, and a power immensely great. This principle has been employed with certain modifications in almost every kind of printing-press that has been brought forward since the period of Lord Stanhope's invention. A view of this press (see the Plate, fig. 2.) will aid the reader in forming an idea of its construction.

For a professed improvement upon the Stanhope press, a patent was taken out by M. de Heine in 1810. The principle of this invention is the application of two sectors, or a sector and a cylinder, or a sector and a roller, to move against the other by a single or compound lever. The only material improvement is the substitution of a spiral or curved inclined plane, instead of the screw.

Some improvements were also made by Mr. Keir, on the construction of the Stanhope press, which have been considered as contributing much to its accurate working and durability. A cylindrical hole is bored in the centre of the press, into which a cylinder is accurately fitted, with the platen fixed on its lower end. To prevent the cylinder from turning round, it is made with a flat side, and a bar of iron, screwed across the two cheeks, bears against this side. Another improvement consists in the spindle, to which the handle is fixed, having a screw cut upon its lower end, which is fitted into a nut, so that when it is turned round, the spindle rises and falls a space equal to that passed over by the descent of the main screw in the same time. By this means, the connecting lever always draws in a horizontal direction. In the other presses, one end remains at the level, while the other descends, which occasions the joints to wear irregularly.

Mr. Brooke, about the same time, applied the compound levers of the Stanhope press to the common press with great success. As the wooden frame of the old press is not sufficient to afford the same resistance as those constructed of iron, the power of these presses is of course much inferior. This improvement, however, has been pretty generally adopted.

Medhurst's printing press is said to excel in the simplicity of its construction. Besides the merit it possesses in this particular, and which renders it cheaper than the Stanhope press, it has, perhaps, a greater advantage in point of power. The pressure is produced by a peculiarly beautiful arrangement of levers, differing considerably from any thing hitherto employed in machinery. This circumstance has led the inventor to denominate his mechanism a new power in mechanics.

This press is similar to the common one in all its parts; but the platen is made the full size of the sheet, and, instead of a screw, a plain spindle is employed. On the lower part of the spindle a circular collar or plate is fixed, into which the bar, or lever, which forms the handle of the press, is fastened. This plate affords steps or cups for two short iron rods or pins which extend up to the head, and are there supported by the points of two screws in the head, entering sockets cut out in the pins, which are made of steel. When the platen is up, these pins stand in an inclined position; but when the spindle is turned by the lever or handle, the circular plate in which the lower end of the pins rest turns round likewise, and, the upper end remaining stationary, they come into a vertical position. In this motion, the spindle and attached platen are forced to descend in the same manner as if a screw were employed.

In 1813 Mr. Ruthven took out a patent for a press, in which the necessary power is produced by a combination of levers alone.

All the alterations or improvements hitherto mentioned,

retain the original principles of placing the types on a moveable carriage, where, after being inked, they are passed under the power for producing the impression, and then returned; the reverse of this is the construction of Ruthven's; and as it is from this his decided point of excellence chiefly arises, we shall be a little particular in explaining it. When the types on the moveable carriage comes under the pressure, a horizontal and perpendicular motion is in action, which effectually prevents that necessary steadiness requisite to produce a clear impression. In Ruthven's presses, the types are fixed on a stationary tablet; the upper surface is brought over by the side till it connects itself at each end with the parts under the tablet, which consists of a combination of levers and cranks, that produce an inconceivable power, and are so placed that while the power is applied at each end, the resisting point is up against the under surface of the tablet; by this arrangement, the horizontal motion with the types is completely avoided; and as the upper surface cannot come in contact with the types till in a situation exactly over them, that point is gained which has been so long desired, of the upper surface descending steadily on the types. Another important object is also here attained, the power being applied at each end of the upper surface, an equality of pressure is thereby diffused, not to be attained by any other press, when the power is applied in the centre of the upper surface. The result arising from these combined advantages is not only a clearness of impression that enables a general observer to distinguish the work printed by them, but, a saving in the durability of the types, from the manner of producing the impression.

The improvement in Mr. Russell's printing press is derived chiefly from the two-fold application of the principle which was first introduced by Lord Stanhope, and which nearly all other press-makers have found it advisable to adopt, though in varied degrees.

The Albion press by Mr. Cope is a contrivance of considerable merit. Its power is very great, its aggregate weight is much less than many others, and the ease with which it may be worked adds much to its importance and value; but our limits prevent us from detailing its particular excellencies. Many other presses besides those we have mentioned have been presented to the public, of which we cannot enter into even an enumeration. There is, however, one, the Columbian press, which from its amazing power, merits a particular, though brief description.

For this press we are indebted to the ingenuity and talent of Mr. George Clymer, of Philadelphia, in North America, who, after manufactured a supply of them for our transatlantic brethren, arrived in this country, in 1817, to introduce his press to the printers of Europe, which had given such universal satisfaction to those connected with the art in that portion of the globe. The highly favourable and very flattering testimonials which Mr. Clymer produced on his arrival in London, from the gentlemen connected with the press in different parts of the United States, where they had been in active operation, clearly evinced to the printers of Great Britain and Europe, that his invention was well deserving their countenance and encouragement; and, notwithstanding they had presses not only of the Stanhopean manufacture, but also of several others, yet the properties of Mr. Clymer's Columbian press, supported by the above testimonials, was the immediate cause of their introduction into several of the first houses in the metropolis, and many of the others soon followed; they were also introduced into several of the first printing-offices on the continent; and we sincerely hope that Mr. Clymer has been handsomely remunerated from them for his ingenuity and ability. Of this extraordinary press, fig. 3, in the Plate, gives a faithful representation; the parts of which we shall briefly describe, to enable pressmen to fix them up or take them down, when they require either cleaning or removing.

This press is composed of the following parts: the feet, staple, ribs, fore-stay, rounce, main lever, elbow-piece, counterpoise lever, links, table, platen, piston, cheek or guide pieces, back bar, back-return lever, shoulder piece, bar, connecting rod, eagle, &c.

Having brought the staple on or near to the spot on which you intend to fix the press, then put the feet (as marked) into their respective places, and raise the staple upon them. The

ribs should now be screwed to the staple, and also the leg, or fore-stay, by which the near end of them is supported, but the stay is not fastened to the floor; at the top of this stay is a projecting piece of iron, with a bolster upon it, which prevents the carriage from running back.

The rounce is attached to the ribs by means of caps and bolts, which are fastened to the projections from the ribs.

The main lever must next be raised into its station: it is connected to the staple by a strong steel bolt, which fits according to a small mark, and is pinned on the other side, to prevent its working out.

The elbow piece is made in the form of two sides of a triangle: it has one square, and three round holes through it; that at the angle is the one which connects it to the projecting part of the long side of the staple, in which is a mortise to receive it; this done, two holes will remain below, and the square one above; the centre round hole receives the bolt, on each end of which is the lower part of the links; the lower hole is for the bolt which attaches the knob piece to the long end of the elbow piece: on the upper end of the last mentioned is the square hole for connecting the back-return lever.

The counterpoise lever (whereon stands the eagle, which causes the return of the platen and bar) works on two pivots on the top of the long side of the staple, and rests upon a small piece of wood in the mouth of the dolphin, on the upper part of the main lever. The counterpoise and main levers are connected by means of a short brass rod, with a hook at one end, and a screw at the other; the former fits into the mouth of the dolphin at the end of the counterpoise lever, and the latter passes through a hole at the end of the main lever, which is drawn up by a nut on the under side, and by which nut the main lever, and consequently the platen, are raised or lowered at pleasure, by screwing or unscrewing this nut.

The links fit on each side of the main lever and the elbow piece, to which they are attached by means of two steel bolts, which are pinned on the opposite side, to prevent their working out; by these links the main lever is drawn down when the impression is taken.

The table is an iron surface turned off in a lathe to the greatest exactness, with long cramps underneath, which run in the ribs, and which act as bearers to the table when the impression is taken; the girths from the barrel of the rounce are fastened to projections attached to the table in the usual manner; corner irons are screwed on as well as the tympan joints, as before described.

The platen is also turned off in a lathe, so as to meet the even surface of the table: in the centre is a high square, on which the piston is fixed, with four holes to receive the ends of the side-headed screws which secure the piston to the platen; ridges project from this square to the ends, corners, and sides of the latter, by which it is prevented from springing when the pull is made; the platen should now be placed on the table with two pieces of wood, about letter height, underneath; the four side-headed screws are next put into their respective holes in the platen (as marked,) and the small wedges placed behind to keep them in their stations: a square piece of iron, or pieces of sheet iron or tin, are laid in the centre of the platen to increase or reduce the power. The piston is now lifted on the small piece of iron in the centre of the platen, and the screws passed through the four holes in the former, and the nuts screwed on, which bind the piston and platen together; care should be taken that the marked sides of the platen and piston are both kept in the front. The table, with the piston and platen, is now run to the centre of the staple, which will bring the upper part of the piston directly under the trunnion of the main lever, which is connected to the piston by means of the caps and bolts attached to the latter. The platen must be regulated by the screws which secure the piston, when a form is laid on.

The check, or guide pieces, which the angles of the piston slide through, and which keep the piston and platen steady, fit on two projections from the insides of the staple, and are fastened by four bolts with nuts and screws. The left-hand one is tightened by means of a small key, or wedge, which passes between the projection from the staple and the check pieces; on the right hand one is a piece of iron with a screw

through it, which the elbow of the bar strikes against when the latter is brought down: this screw is for the purpose of partially regulating the power.

The back bar slides into two bevels on the back of the staple, behind the main lever, which is for the purpose of preventing the staple from springing, when the power is applied by means of the bar.

The back-return lever fits into the square hole in the upper angle of the elbow piece; it has a small sliding weight, which acts a counterpoise to the eagle on the top lever.

The bar, or shoulder piece, fits into two projections from the off-side of the staple, to which one end is attached by a steel bolt, and in the other is a square hole made to receive the end of the bar, which is pinned on the inside: the middle of the shoulder piece is cast hollow, to admit one end of the connecting rod, which is attached by a small bolt.

The connecting rod is made of wrought iron: one end has an eye, which fits between the hollow in the middle of the shoulder piece, through both of which pass a small pin; the other end is tapped, to screw on the swivel attached to the knob piece, and by which, from the bar, the whole machine is put into motion. It should be recollected, that one side of the eye is filed away to admit the rod to vary a small degree from a right angle, otherwise it would not meet the swivel attached to the knob piece. To increase the power, take out the small bolt in the middle of the shoulder piece, and turn the rod to the right; that is, take up the screw: to diminish it, turn the rod to the left, viz. lengthen the rod by unscrewing: the filed part of the eye must always be kept downwards.

Composition Inking Balls.—Having noticed the principal improvements that have been made in printing presses, those which have taken place in the means of supplying the type with ink must not be omitted. Until of late, the common pelt balls, consisting of sheep skin stuffed with wool, and nailed to the ball stock, were in constant use, and in many places their services are still retained. About the year 1816 composition balls first made their appearance at Weymouth, being made by Mr. B. Foster, a compositor, of that place. At first their introduction was much opposed by many masters and pressmen in London, but they have gradually gained ground and got into general use. These balls are made of molasses, glue, and a portion of tar, which are boiled together to a proper consistency. It is then poured on a piece of cloth, and when sufficiently cold is nailed to the ball-stock like the common sheep skin. Should these balls be hard, when dirty, they may be washed with a little weak lye, and rinsed with water; if soft, a little ink may be laid on them and scraped: but every pressman must use his own judgment, as variations will arise from boiling and the state of the weather.

When the Times newspaper was first printed by machinery, the power being cylindrical, rollers were indispensably necessary. These were formed of the above composition, and being found to answer the expected purpose, in 1819 hand rollers were introduced to the notice of the pressmen. These came very rapidly into use, and are likely to continue. They are coated with the above composition, and made in the form represented in fig. 4. They have been found admirably adapted for heavy forms, but not so well for light ones, and are subject to the changes of the weather. The inking frames or tables by which the rollers are supplied with ink, are constructed as represented in fig. 5. The whole is composed of iron, with the cylinder turned off to the greatest exactness, under which is a steel edge that scrapes the ink off the cylinder, to the exact quantity required. This is regulated by means of counterpoise levers that pass under the table, on which are hung two weights, to be removed according to the quantity required for the work in hand. One end of each lever passes against the *ductor* or *regulator*. The ductor and cylinder are fixed so closely together that the cavity will hold water, and consequently no ink can escape more than is actually wanted. The cylinder has an ornamental cover, which is always kept on, except when a fresh supply of ink is required. By this means all dust and dirt is kept from the ink and the cylinder. The latter is moved by a small handle at the end. The table is turned off in a lathe perfectly true, the same as in the presses.

Printing Machines.—Among the numerous inventions of the

present age, those of machines for printing are not the least remarkable. Prior to their introduction, the press department was one of great labour, whenever extraordinary expedition was required. This was particularly the case with newspapers, of which, with the utmost exertion, scarcely ever more than 750 copies could be produced in an hour. The consequence was, that in newspaper offices, where the circulation was extensive, it was found necessary, in order to get the paper published in time, to compose two or more copies, so that by going to press at the same time, the demands of the public might be complied with; thus occasioning an enormous increase of expenditure both in the compositors' and press departments. In a newspaper circulating seven or eight thousand copies, this expense, annually, could not have been less than £2000; all of which has been saved by the introduction of machines, which are worked by steam or hand.

The first machine used in London was made, we believe, by two Saxons, named König and Baur, in 1814. This machine, or one upon a similar principle, is now in use, worked by steam, at the Times' office, and there are others in various other offices. The great expense of erecting machines worked by steam, led to the invention of others, which are worked by hand, but which have been liable to many objections on the score of the labour requisite in turning the wheel, and the injury to the type. It appears, that Mr. Miller, of Fleet-street, after an expenditure of several thousand pounds, and the most unwearied exertions, has succeeded in producing a machine capable of working 2000 sheets per hour, without any danger of accident, and with comparatively little labour to the persons employed; whilst, from the simplicity of the construction, and the regularity of the action, the type has not even the ordinary wear of the common printing press.

The machine, which appears in fig. 6 in the engraving, will communicate to the reader some idea of the manner in which the operation is performed:—A boy is represented as laying on A, the sheet of white paper, B is the cylinder which prints the first side of the paper, C intermediate cylinders over which the paper travels to D, the cylinder which gives the final impression. At E are the inking rollers, under which the form (that is, the types) is in the act of passing; F is the reservoir of ink, from which the inking rollers are supplied; G is the form receiving the last inking under the printing cylinder. At H, is seen a sheet just delivered into the hands of another boy, whose business it is to keep the sheets, as they come out, in a heap. The lines at the top of the machine represents the tapes which run round the cylinders and secure the sheet. In this curious process the form of types is placed on a carriage, which slides backwards and forwards along rails upon the fixed frame of the machine, so as to pass beneath the surface of the large printing cylinder. The blank sheet of paper being laid on the tympan, is carried down between rollers and tapes under the cylinder, which presses it upon the form of types, and prints it. It is thence conducted forwards, and delivered on other tapes to the boy who is stationed to receive it. The tapes which carry the sheet of paper along the surface of the cylinder, are narrow enough to lie in the spaces between the pages for printing; they, therefore, do not prevent the sheet from applying itself to the types, although they pass entirely across its surface, so as to keep it in place. These tapes are arranged over small pulleys, which can be fixed at any required distance apart, so as to accord with the spaces between the pages for printing different kinds of work, such as folios, quartos, octavos, &c. The mode of procuring register is by points, which can be moved with every facility in any direction.

The machine has two distinct sets of inking apparatus, one at each end, being so arranged as to furnish and distribute the ink, by means of elastic composition rollers, upon the form of types, as it moves backwards and forwards underneath them. The reservoirs of ink from which the rollers are supplied, are fixed on each end of the carriage, near which are also other rollers to distribute the ink uniformly over the surface of the inking rollers. The rollers being made to pass twice over the types before an impression is made from them, produce an effect in inking them, equivalent to what would be afforded by passing the common inking roller four times over

them, which is all that is usually deemed necessary to distribute the ink equally over the types, so as to render the impression clear and uniform. The feeding roller is supplied with ink by means of a trough and regulating scraper. While the impression is being produced, the receiving roller is brought in contact with the feeding roller while in motion, and receives a sufficient quantity of ink for the next impression, while the type carriage is returning to its first position. The distributing roller, whilst revolving, has, at the same time, a lateral motion given to it, in order to distribute the ink over the whole surface of the composition rollers. The power of the pressing cylinder, and of the inking roller, can be regulated and adjusted with mathematical accuracy, so that a strong or a light impression, as the nature of the work may require, can be given with the utmost nicety.

Several of these printing machines are now in constant use in the metropolis, varying from each other in some subordinate particulars, but all founded on one common principle. Since the first introduction of machines, they have been considerably simplified, particularly in the complexity of their inking apparatus. For this we are indebted to the genius of Messrs. Applegath and Cowper, who have produced a machine far superior to that by Mr. König, and which possesses nothing in common with it, but the pressing cylinders, the inking rollers, and the tapes to hold the sheet of paper on the cylinders. The pressing cylinders and inking rollers were first suggested by Mr. Nicholson; and tapes are similarly used in machines for the ruling of paper for account books. These gentlemen, therefore, though producing their machine subsequently to Mr. König, cannot, with justice, be accused of having, in the slightest degree, infringed upon his invention. Mr. König's machine possessed originally *sixty* wheels; Messrs. Applegath and Cowper's but *sixteen*; and the machines of the former are now almost entirely superseded, even in the office of Mr. Bensley, the principal proprietor of König's patent, by the improved machines of Applegath and Cowper.

PRISM, in Geometry, is a body, or solid, whose two ends are any plain figures which are parallel, equal, and similar; and its sides connecting those ends are parallelograms. Hence, every section parallel to the base, is equal and similar to the base; and the prism may be considered as generated by the parallel motion of this plane figure. Prisms receive particular names, according to the figure of their bases; as a *triangular prism*, a *square prism*, a *pentagonal prism*, a *hexagonal prism*, and so on. And hence the denomination prism comprises also the cube and parallelepipedon, the former being a *square prism*, and the latter a *rectangular one*. And even a cylinder may be considered as a round prism, or one that has an infinite number of sides. Also a prism is said to be regular or irregular, according as the figure of its end is a regular or an irregular polygon. The axis of a prism, is the line conceived to be drawn lengthways through the middle of it, connecting the centre of one end with that of the other end. Prisms, again, are either right or oblique. A right prism is that whose sides and its axis are perpendicular to its ends, like an upright tower. And an oblique prism, is when the axis and sides are oblique to the ends; so that, when set upon one end, it inclines on one hand more than on the other. The principal properties of prisms are, 1. That all prisms are to one another in the ratio compounded of their bases and heights. 2. Similar prisms are to one another in the triplicate ratio of their like sides. 3. A prism is triple of a pyramid of equal base and height; and the solid content of a prism is found by multiplying the base by the perpendicular height. 4. The upright surface of a right prism is equal to a rectangle of the same height, and its breadth equal to the perimeter of the base or end. And therefore such upright surface of a right prism, is found by multiplying the perimeter of the base by the perpendicular height. Also the upright surface of an oblique prism is found by computing those of all its parallelogram sides separately, and adding them together. And if to the upright surface be added the areas of the two ends, the sum will be the whole surface of the prism.

PRISM, in Optics, is an instrument employed for shewing the properties of solar light, and consists merely of a triangular prism of glass, which separates the rays of light in their pas-

rays through it, in consequence of the different degrees of refrangibility that has place in the component part of the same ray. It is, for instance, by means of this instrument that the origin of colours is shown to be owing to the composition which takes place in the rays of light, each heterogeneous ray consisting of innumerable rays of different colours. Thus, a ray being let into a darkened room, through a small round aperture *x*, and falling on a triangular glass prism *z*, is by the refraction of the prism considerably dilated, and will exhibit on the opposite wall an oblong image *ab*, called a spectrum, variously coloured, the extremities of which are bounded by semi-circles, and the sides rectilinear.

The colours are commonly divided into seven, which, however, have various shades, gradually intermixed at their juncture. Their order, beginning from the side of the refracting angle of the prism, is red, orange, yellow, green, blue, purple, and violet. The obvious conclusion from this experiment is, that the several component parts of solar light have different degrees of refrangibility, and that each subsequent ray in the order above mentioned, is more refrangible than the preceding. As a circular image would be depicted by the solar ray undisturbed by the prism, so each ray that suffers no dilation by the prism would mark out a circular image *O*. Hence, it appears that the spectrum is composed of innumerable circles of different colours. The mixture, therefore, is proportionable to the number of circles mixed together; but all such circles lie between those of two contiguous circles, consequently the mixture is proportionable to the interval of those centres; viz. to the breadth of the spectrum. Consequently, if the breadth can be diminished, retaining the length of the rectilinear sides, the mixture will be lessened proportionably; and this is done by the following process:—At a considerable distance from the hole *x*, place a double convex lens *A B*, whose focal length is equal to half that distance, and place the prism *z* behind the lens; then at a distance behind the lens, equal to the distance from the hole, will be formed a spectrum, the length of whose rectilinear sides is the same as before, but its breadth much less; for the undiminished breadth was equal to a line subtending, at the distance of the spectrum from the hole, an angle equal to the apparent diameter of the sun, together with a line equal to the diameter of the hole; but the reduced breadth is equal to the diameter of the hole only: the image of the hole formed by the lens, at the distance of double its focal length, is equal to the hole; therefore its several images, in the different kinds of rays, are equal to the same; viz. the breadth of the reduced spectrum is equal to the diameter of the hole. It is also known from experiment, that a prism placed in an horizontal position will project the ray into an oblong form, but if another horizontal prism be applied, similar to the former, to receive the refracted light emerging from the first, and having its refracting angle turned the contrary way from that of the former, the light, after passing through both prisms, will assume a circular form, as if it had not been at all refracted. But if the light, after emerging from the first prism be received on another prism, perpendicular to the former, it will be refracted by this into a position inclined to the former, but its breadth will remain the same. In order now to show that the different colours suffer no manner of change from any number of refractions, let there be placed close to the prism a perforated board, and let the refracted light transmitted through the hole be received on another board parallel to the former, and likewise perforated with a small hole; and behind this hole place another prism with its refracting angle downwards, and turn the first prism slowly about its axis, and the light will then move up and down the second board; let the different colours be turned successively, and mark the place of the different coloured rays on the wall after their refraction at the

second prism; it will then be found that the red is seen the lowest, and the violet the highest, and the rest in the intermediate space in their order. From these experiments, aided by some others which our limits will not admit of detailing, the following conclusions have been drawn, viz. The solar rays may be resolved into different coloured rays; these coloured rays are immutable, either by reflection or refraction. That from the mixture of these coloured rays in due proportion solar light may be produced; and consequently that the differently coloured rays exist in solar light, though, when blended together in their natural proportions, it exhibits no traces of colour. See COLOUR.

PRISMOID, a figure resembling a prism.

PRISON, a goal, or place of confinement.

PRISTIS, or saw-fish, a genus of fishes of the order chondropterygi: there are five species.

PRIVATEER, a vessel of war, armed and equipped by particular merchants, and furnished with a military commission from the state, to cruise against and annoy the enemy, by taking, sinking, or burning their shipping.

PRIVILEGE, in Law, some peculiar benefit granted to certain persons or places, contrary to the usual course of the law.

PRIVY, in Law, denotes one who is partaker, or has an interest in an affair.

PRIVY COUNCIL, is the principal council belonging to the king, and is generally called by way of eminence the council. Privy counsellors are made by the king's nomination, without either patent or grant; and on taking the necessary oaths, they become immediately privy counsellors, during the life of the king that chooses them, but subject to removal at his discretion: no convenience now arises from the extension of the privy council, as these only attend who are especially summoned for that particular occasion.

PRIVY SEAL, is a seal that the king uses to such grants, or other things as pass the great seal.

PRIZE, a vessel taken from the enemy. Vessels are looked on as prizes, if they fight under any other standard than that of the state from which they have their commission, if they have no charter-party, invoice, or bill of lading, aboard; if loaded with effects belonging to the king's enemies, or even contraband goods. Those of the king's subjects recovered from the enemy, after remaining four-and-twenty-hours in their hands, are deemed lawful prize. Vessels that refuse to strike may be constrained; and if they make resistance and fight, become lawful prize if taken. By stat. 13 Geo. II. ch. 4, judges and officers failing of their duty in respect to the condemnation of prizes, forfeit £600 with full costs of suit, one moiety to the king, and the other to the informer.—The regulations with regard to prizes in the royal navy are as follow: 1. When any ship or vessel is taken from the enemy, the hatches are to be immediately spiked up, and her lading and furniture secured from embezzlement, till sentence is passed upon her in some court of admiralty empowered to take cognizance of cases of that nature. 2. The captain is to cause the officers of the prize to be examined: three or more of the company, who can give best evidence, to be brought to the said court of admiralty, together with the charter-parties, bills of lading, and other ships' papers found on board. Articles 3 and 4 relate to the finding any of the king's subjects in the prizes. 5. When a privateer is taken, great care is to be had to secure all the ships' papers, especially the commission: but if there be no legal commission found on board, then all the prisoners are to be carried before some magistrate, in order to their being examined and committed as pirates.

PRIZE MONEY, the profits arising from the sale of such prize. In ships of war, the prize money is to be divided among the officers, seamen, &c. as his majesty shall appoint by proclamation; but among privateers, the division is according to the agreement between the owners.

PRIZING, the application of a lever to move any weighty body, as an anchor, &c.

PROBABILITY OF AN EVENT, is the doctrine of Chances, is the ratio of the number of chances by which the event may happen, to the number by which it may both happen and fail. So that, if there be constituted a fraction, of which the numerator is the number of chances for the events happening, and

the denominator the number for both happening and failing, that fraction will properly express the value of the probability of the event's happening.

PROBABILITY of Life. See **EXPECTATION.**

PROBABILITIES, the same as **CHANCES.**

PROBATE of WILLS, is the exhibiting and proving wills or testaments before the ecclesiastical judges.

PROBE, a surgeon's instrument for examining the circumstances of wounds, &c.

PROBLEM, in Logic, a proposition that neither appears absolutely true nor false, and consequently may be asserted either in the affirmative or negative.

PROBLEM, in Geometry, is a proposition wherein some operation or construction is required; as, to divide a line or angle erect, or let fall perpendiculars.

PROBLEM, in Algebra, is a question or proposition which requires some unknown truth to be investigated, and the truth of the discovery demonstrated.

PROBOSCIS, in Natural History, is the trunk or snout of an elephant, and some other beasts and insects.

PROCEDENDO, is a writ which lies where a cause is removed out of an inferior to a superior court.

PROCELLARIA, the petrel, in Natural History, a genus of birds of the order anseres. There are twenty-three species, of which the following are the principal:—The giant petrel, more than three feet long, and about seven wide. These birds are often seen sailing just above the water without moving their wings for a long time together, and being particularly alert on the approach of storms, often fill the mariners with apprehension and alarm. They abound most in southern latitudes, and though their principal food is fish, devour also the putrid carcasses of seals and whales.—The pintado petrel, abounds about the coasts of the Cape of Good Hope. These birds are about the size of the kittiwake, and are often observed in such numbers that many hundreds have been taken in one night.—The fulmar petrel weighs nearly a pound and a half, and is found in the northern coasts of this island, and thence even beyond Iceland and Greenland, where the natives use it for food, though its flesh is highly offensive to those not used to it. The fat is burnt in their lamps. These birds subsist chiefly on fish, but often banquet on the carcasses of whales, particularly the fat parts, which they afterwards eject from their stomachs into the mouths of their young. They often spurt it in the faces of their enemies, and exhibit indeed no other mode of resistance. They are stated to be so amazingly fat, that, on being passed through the hands with great compression, the fat flows off like oil.—The shear-water petrel is smaller than the last. These birds are found in vast numbers in the Orkneys, where they are highly valued for their feathers as well as flesh.—The stormy petrel is of the size of a swallow, and rarely seen but at sea; and in tempestuous weather numbers are observed following, as if for shelter, in the wakes of vessels. They dive sometimes for half an hour together, and live principally upon fish, but will eat a variety of offal thrown from ships.—In the Ferro Islands they are so astonishingly fat, that the natives are stated to use them as candles, after drawing a wick through their bodies.

PROCESS, in Law, is the manner of proceeding in every cause, being the writs and precepts that proceed, or go forth, upon the original upon every action, being either civil or criminal.

PROCLAMATION, a public notice given of any thing of which the king thinks proper to advertise his subjects.

PROCTOR, a person commissioned to manage another person's cause, in any court of the civil or ecclesiastical law.

PROCURATOR, a person who has a charge committed to him to act for another.

PROCYON, a fixed star of the second magnitude in the constellation *CANIS MINOR*.

PROD, is a vessel used in the South Seas. This name, which signifies flying, has obtained on account of the swiftness with which it sails, being, with a brisk trade wind, near twenty miles an hour. It is chiefly used by pirates.

PRODUCING, in Geometry, signifies the drawing out a line farther till it has any assigned length.

PRODUCT, in Arithmetic and Algebra, is the quantity arising from the multiplication of two or more factors together.

PROFILE, denotes the outline of a figure, building, member of architecture, &c.

PROFILE, in Sculpture and Painting, denotes a head, portrait, &c. when represented sideways, or in a side view.

PROGRESSION, an orderly advancing or proceeding in the same manner, course, tenor, proportion, &c.

PROGRESSION, in Arithmetic and Algebra, a series of numbers advancing or proceeding in the same manner, or according to a certain law, &c.—Progression is either arithmetical, or geometrical.

Arithmetical PROGRESSION, is a series of three or more quantities that have all the same common difference; as 3, 5, 7, &c. which have the common difference 2; and $a, a + d, a + 2d$, &c. which have all the same difference d .

PROHIBITION, is a writ properly issuing only out of the Court of King's Bench, being the king's prerogative writ; but, for the furtherance of justice, it may now also be had in some cases out of the Court of Chancery, Common Pleas, or Exchequer, directed to the judge and parties of a suit in an inferior court, commanding them to cease from the prosecution thereof, upon a suggestion, that either the cases originally, or some collateral matter arising therein, does not belong to that jurisdiction, but the cognizance of some other court. Upon the court being satisfied, that the matter alleged by the suggestion is sufficient, the writ of prohibition immediately issues.

PROJECTILES, are such bodies as, being put in a violent motion by any great force, are then cast off or let go from the place where they received their quantity of motion; as a stone thrown from a sling, an arrow from a bow, a bullet from a gun, &c. See **GUNNERY**.

PROJECTION, in Mechanics, the art of giving a body its projectile motion. See **PROJECTILES**.

PROJECTION, in Perspective, denotes the appearance or representation of an object on the perspective plane. See **PERSPECTIVE**.

PROJECTION of the Sphere in Plano, is a representation of the several points or places of the surface of the sphere, and of the circles described upon it, upon a transparent plane placed between the eye and the sphere, or such as they appear to the eye placed at a given distance. The principal use of the projection of the sphere is in the construction of planispheres, maps, and charts, which are said to be of this or that projection, according to the several situations of the eye, and the perspective plane, with regard to the meridians, parallels, and other points or places so represented. The most usual projection of maps of the world, is that on the plane of the meridian, which exhibits a right sphere, the first meridian being the horizon. The next is that on the plane of the equator, which has the pole in the centre, and the meridians the radii of a circle, &c. The projection of the sphere is usually divided into orthographic and stereographic; to which may be added gnomonical.

Orthographic PROJECTION, is that in which the surface of the sphere is drawn upon a plane cutting it in the middle; the eye being placed at an infinite distance vertically to one of the hemispheres.

Stereographic PROJECTION of the Sphere, is that in which the surface and circles of the sphere are drawn upon the plane of a great circle, the eye being in the pole of that circle.

Gnomonical PROJECTION of the Sphere, is that in which the surface of the sphere is drawn upon an external plane commonly touching it, the eye being at the centre of the sphere.

PROLATE, in Geometry, a term applied to a spheroid produced by the revolution of a semi-ellipse about its transverse diameter; and is thus distinguished from an oblate sphere, which is produced by the revolution of the ellipse about its conjugate diameter.

PROMISE, is where, upon a valuable consideration, persons bind themselves by words to do or perform such a thing agreed on: it is in the nature of a verbal covenant, and wants only the solemnity of writing and sealing to make it absolutely the same. Yet for the breach of it, the remedy is different; for instead of an action of covenant, there lies only an action upon the case, the damages whereof are to be estimated and determined by the jury.

PROMONTORY, a high cape, or head-land.

PRONOUN, in Grammar, a declinable part of speech, which being put instead of a noun, points out some person or thing.

PRONUNCIATION, in Grammar, the manner of articulating the words of a language.

PROOF, the shewing or making plain the truth of any matter alleged; either in giving evidence to a jury on a trial, or else on interrogatories, or by copies of records, or exemplifications of them.

PROPORTION, is often confounded with ratio; but they are quite different things. For, ratio is properly the relation of two magnitudes or quantities of one and the same kind; as the ratio of 4 to 8, or 15 to 30, or of 1 to 2, and so implies or respects only two terms or things. But proportion respects four terms or things, or two ratios which have each two terms; though the middle term may be common to both ratios, and then the proportion is expressed by three terms only, as 4, 8, 64, where 4 is to 8 as 8 to 64.

PROPORTION, in Mathematics, is an equality or similitude of ratio; thus, if the ratio a to b is the same as that of c

to d ; that is, if $\frac{a}{b} = \frac{c}{d}$, then a, b, c, d are in proportion, which

is denoted by placing the quantities thus; $a : b :: c : d$, or $a : b = c : d$, and is read as a is to b , so is c to d .

PROPORTION, though sometimes confounded with ratio, differs from it in this, that ratio has only a relation to two quantities of the same kind, whereas proportion relates to the comparison of two such ratios.—Proportion differs also from progression in this, that in the former it is only required that there should be an equality between the ratio of the 1st and 2nd term, and that of the 3d and 4th; whereas to constitute a progression there must be the same ratio between each two adjacent terms: these two cases, however, are sometimes distinguished by the terms *discrete* and *continued* proportion.

PROPORTION, is also *direct* and *inverse*, or *reciprocal*, *alternate*, &c. Thus if the ratio of a to b is equal to the ratio c to d , then,

direct	$a : b :: c : d$
inversion	$b : a :: d : c$
alternate	$a : c :: b : d$
composition	$a + b : b :: c + d : d$
conversion	$a + b : a :: c + d : c$
division	$\frac{a-b}{b} : \frac{a}{b} :: \frac{c-d}{d} : \frac{c}{d}$
	$a - b : b :: c - d : d$

PROPORTION, is again distinguished into arithmetical, geometrical, and harmonical.

Arithmetical PROPORTION, is the equality of two arithmetical ratios or differences. As in the numbers 12, 9, 6; where the difference between 12 and 9, is the same as the difference between 9 and 6, viz. 3. And here the sum of the extreme terms is equal to the sum of the means, or to double the single mean when there is but one. As $12 + 6 = 9 + 9 = 18$.

Geometrical PROPORTION, is the equality between two geometrical ratios, or between the quotients of the terms. See the preceding article.

Harmonical PROPORTION, is when the first term is to the third, as the difference between the 1st and 2d is to the difference between the 2d and 3d; or in four terms when the 1st is to the 4th, as the difference between the 1st and 2d is to the difference between the 3d and 4th; or the reciprocals of an arithmetical proportion are in harmonical proportion. As 6, 4, 3; because $6 : 3 :: 6 - 4 = 2 : 4 - 3 = 1$; or because $\frac{1}{6}, \frac{1}{4}, \frac{1}{3}$ are in arithmetical proportion, making $\frac{1}{6} + \frac{1}{3} = \frac{1}{4} + \frac{1}{4} = \frac{1}{2}$. Also the four 24, 16, 12, 9, are in harmonical proportion, because $24 : 9 :: 8 : 3$.

Compass of PROPORTION, a name by which the French, and some English authors, call the sector.

PROPORTIONAL, relating to proportion, as proportional compasses, parts, scales, spiral, &c. for which see the respective terms.

PROPORTIONAL, also denotes one of the terms of a proportion, which receives particular denominations according to the place it holds in the proportion, as a *mean* proportional, a *third*, *fourth*, &c. proportional.

Mean PROPORTIONAL, is the middle term of three continued geometrical proportionals. See *MEAN PROPORTIONAL*.

Fourth PROPORTIONAL, is the fourth term of a geometrical proportion, which is found arithmetically by dividing the product of the second and third terms by the first.

To find a fourth Proportional to three given Lines, A, B, C.—

From any point D draw two lines, making any angle G D H. In these lines take D F equal to the first term A, D E equal to the second B, and D H equal to the third C. Join F E, and draw H G parallel to it, and D G will be the fourth proportional required. That is,

$$D F (A) : D E (B) :: D H (C) : D G.$$

Third PROPORTIONAL, is the third of three terms in continued proportion, and is found arithmetically by dividing the square of the second term by the first.

To find a third Proportional to two given Lines, A and B.—

From any point C draw two right lines, making an angle F C G. In these lines take C E equal to the first term A, and C G, C D, each equal to the second term B. Join E D, and draw G F parallel to it; and C F will be the third proportional required. That is,

$$C E (A) : E G (B) :: C D (B) : C F.$$

To cut a Line in extreme and mean Proportion; that is, so that the whole line may be to the greater part, as the greater part is to the less.

Let A B be the given line, and draw B C perpendicular to it and equal to half of it. From the centre C with radius C B describe the circle D B F; join A C, and with A D as radius and A as a centre, describe the arc D E cutting A B in E, so shall the line A B be divided in extreme and mean proportion in the point E.

PROPOSITION, in Logic, part of an argument wherein some quality, either negative or positive, is attributed to a subject.

PROPOSITION, in Mathematics, is either some truth advanced, which is to be demonstrated, or some operation proposed, which is to be performed and shown to be that which was required. Being, in the former case, called a theorem, and in the latter a problem.

PROSODY, that part of Grammar which treats of the quantities and accents of syllables, and the manner of making verses.

PROSOPOPEIA, a figure in Rhetoric, whereby we raise qualities, or things inanimate, into persons.

PROSTHAPHERESIS, is the same as the EQUATION of the Centre.

PROSTYLE, in ancient Architecture, a range of columns in front of a temple.

PROTEST, when one openly affirms, that he does either not at all, or but conditionally, yield his consent to any act, or unto the proceeding of a judge in court wherein his jurisdiction is doubtful, or to answer upon his oath any farther than by law he is bound.

PROTEST, is also that act by which the holder of a bill of exchange declares, that such bill is dishonoured.

PROTEST, in naval language, an instrument drawn up in writing, and attested before a justice of the peace (or a consul or vice-consul in foreign parts,) by the master of a merchant-ship and a part of the ship's crew, after the expiration of a voyage, describing the severity of the voyage, whereby the ship has suffered, or may suffer, in her hull, rigging, or cargo. It is chiefly intended to shew that such damages did not happen through any neglect or misconduct of the master or his officers, &c.

PROTESTANT, a name first given in Germany to those who adhered to the doctrine of Luther; because in 1529 they protested against a decree of the emperor Charles V. and the diet of Spire; declaring, that they appealed to a general council.

The same name also has been given to those of the sentiments of Calvin, and is now become a common denomination for all those of the reformed churches.

PROTHONOTARY, a term which properly signifies first notary, and which was anciently the title of the principal notaries of the emperors of Constantinople. Prothonotary with us is used for an officer in the Courts of King's Bench and Common Pleas; the former of which courts has one, and the latter three. The prothonotary of the King's Bench records all civil actions sued in that court, as the clerk of the crown-office does all criminal causes. The prothonotaries of the Common Pleas enter and enrol all declarations, pleadings, assizes, judgments, and actions; they also make out all judicial writs, except writs of habeas-corpus, and distringas jurator, for which there is a particular office, called the *habeas corpora* office; they likewise enter recognisances acknowledged, and all common recoveries; make exemplification of records, &c.

PROTOXIDE, in Chemistry, a term used to denote the minimum of oxidizement.

PROTRACTION, the same with plotting.

PROTRACTOR, is the name of an instrument used for protracting or laying down on paper the angles of a field or other figure. The protractor is a small semicircle of brass, or other solid matter, the limb or circumference of which is nicely divided into one hundred and eighty degrees; it serves not only to draw angles on paper, or any plane, but also to examine the extent of those already laid down. For this last purpose let the small point in the centre of the protractor be placed above the angular point, and make the side coincide with one of the sides that contain the angle proposed; then the number of degrees cut off by the other side, computing on the protractor, will shew the quantity of the angle that was to be measured. Protractors are now more usually made in the form of a parallelogram, and properly graduated at the upper edge.

PROVIDENCE, the conduct and direction of the several parts of the universe, by a superior intelligent Being.

PROVINCE, the circuit of an archbishop's jurisdiction.

PROVISO, in Law, a condition inserted in a deed, upon the observance whereof the validity of the deed depends.

PROVOST, an officer, whereof there are divers kinds, civil, military, &c.

PROVOST of a city or town, is the chief municipal magistrate in several trading cities, particularly in Scotland, being the same with mayor in England.

PROVOST Marshal of an Army, is an officer appointed to seize and secure deserters, and all other criminals. He is to hinder soldiers from pillaging, to indict offenders, and to see the sentence passed on them executed. He also regulates the weights and measures, and the price of provisions, &c. in the army.

PROVOST-MARSHAL, an officer appointed to take charge of prisoners at a court-martial.

PROW, a name given by seamen to the beak or pointed cut-water of a xebec, galley, or polacre. The upper part of the prow is usually furnished with a grating platform for the convenience of the seamen, who walk out to perform whatever is necessary about the sails or rigging on the bowsprit.

PRUNELLA VULGARIS. (*Selfheal*.) The leaves have an herbaceous roughish taste, and hence stand recommended in hemorrhages and alvine fluxes. It has been principally celebrated as a vulnerary, whence its name; and in gargarisms for aphthæ and inflammations of the fauces.

PRUNELLÆ, SAL, a preparation of purified salt-petre.

PRUNES, are plums dried in the sunshine, or in an oven.

PRUNING, in Gardening and Agriculture, is the lopping off the superfluous branches of trees, in order to make them bear better fruit, grow higher, or appear more regular. Pruning, though an operation of very general use, is nevertheless rightly understood by few; nor can it be learned by rote, or, indeed, wholly by books, but requires a strict observation of the different manners of growth of the several sorts of fruit trees; the proper method of doing which cannot be known, without carefully observing how each kind is naturally disposed to produce its fruit; for some do this on the same year's wood as vines; others, for the most part, upon the former year's wood, as peaches, nectarines, &c. and others, upon spurs which are

produced upon wood of three, four, &c. to fifteen or twenty years' old, as pears, plums, cherries, &c. therefore, in order to the right management of fruit trees, provision should always be made, to have a sufficient quantity of bearing wood in every part of the trees, and at the same time there should not be a superfluity of useless branches, which would exhaust the strength of the trees, and cause them to decay in a few years. The reasons for pruning of fruit trees are, 1. To preserve them longer in a vigorous bearing state: 2. To render them more beautiful: and, 3. To cause the fruit to be larger and better tasted.

PRUNUS, a genus of the monogynia order, in the insectaria class of plants; and in the natural method ranking under the 36th order pomaceæ. There are thirty-three species.

PRUNUS DOMESTICA. (*The Common Plum Tree*.) The medical effects of the damson and common prunes are, to abate heat, and gently loosen the belly; which they perform by lubricating the passage, and softening the excrement. They are of considerable service in costiveness accompanied with heat or irritation, which the more stimulating cathartics would tend to aggravate: where prunes are not of themselves sufficient, their effects may be promoted by joining with them a little rhubarb or the like; to which may be added some carminative ingredient, to prevent their occasioning flatulencies. *Prunellæ* have scarce any laxative quality; these are mild, grateful refrigerants, and by being occasionally kept in the mouth, usefully allay the thirst of hydropic persons.

PRUNUS LAURO-CERASUS. (*The Common Laurel*.) The leaves of the laurel have a bitter taste, with a flavour resembling that of the kernels of the peach or apricot; they communicate an agreeable flavour to aqueous and spirituous fluids, either by infusion or distillation. The distilled water applied to the organs of smelling strongly impresses the mind with the same ideas as arise from the taste of peach blossoms or apricot kernels: it is so extremely deleterious in its nature, and sometimes so sudden in its operation, as to occasion instantaneous death; but it more frequently happens that epileptic symptoms are first produced. This poison was discovered by accident in Ireland in the year 1728; before which, it was no uncommon practice there, to add a certain quantity of laurel water to brandy, or other spirituous liquors, to render them agreeable to the palate. At that time three women drank some laurel-water; and one of them a short time afterwards became violently disordered, lost her speech, and died in about an hour. A gentleman at Guildford, some few years back, also, by making an experiment as he intended on himself, was poisoned by a small dose: he did not survive the taking it more than two hours. In consequence of the above poisonous principle existing in the laurel, it has been recommended to persons to be cautious how they make use of the leaves of that shrub, which is a usual practice with cooks for giving flavour to custards, blanch-mange, and other made-dishes, lest the narcotic principle should be also conveyed, to the detriment of the health of persons who eat of them. And the same may be said of the kernels of all stone-fruits; for the flavours given to noyas, ratafia, and other liquors which are highly prized by epicures, are all of them derived from the same principle as laurel-water, and which, on chemical investigation, is found to be prussic acid. This exists in considerable quantities in the bitter almond, and which when separated proves to be the most active poison known, to the human as well as all other animal existence. This principle, and its mode of extraction, should be made equally as public as the necessity of scientific researches requires. We cannot with propriety accuse either this tree or the laurel as being poisonous, because the ingenuity of mankind has found out a mode of extracting this active acidulous principle, and which is so very small in proportion to the wholesome properties of the fruit, as not to be suspected of any danger but for this discovery. As well might we accuse wheat of being poisonous, because it yields on distillation brandy, which has been known to kill many a strong-bodied fellow who has indulged in this favourite beverage to excess. An eminent chemist observes, that he has made experiments with the oxalic acid, and found that when this was also concentrated, it has similar effects; inasmuch that no animal can contain a grain of it if taken into the throat or sto-

mech: and thus might we also be led to consider the elegant, and in itself harmless, wood-sorrel, as a poisonous plant.

PRUSSIC ACID, in Chemistry and the Arts, is one of the most important of the acids. It was discovered by accident about the beginning of the last century by Diebach, a chemist of Berlin. This gentleman wishing to precipitate a decoction of cochineal with an alkali, got some potash, on which he had distilled for several times his animal oil, and as there was some sulphate of iron in the decoction, the liquor instantly exhibited a beautiful blue in the place of a red precipitate. Hence he saw the method of producing the same substance at pleasure, and it soon became an object of commerce, and obtained the name of Prussian blue, from the place where it was discovered. This substance is now formed chiefly during the decomposition of animal substances in high temperatures. Three parts of blood, evaporated to dryness in an iron dish, are to be mixed with one part of sub-carbonate of potash (common pearlash), and calcined in a crucible, which should be only two-thirds filled by the materials, and covered with a lid. The calcination must be continued with a moderate heat as long as the flame issues from the crucible; and when it becomes faint, and likely to be extinguished, the process must be stopped. Throw the mass when cold, into ten or twelve parts of water; allow it to soak a few hours, and then boil them together in an iron kettle. Filter the liquor, and continue pouring hot water on the mass as long as it acquires any taste. To this solution add one composed of two parts of alum and one of sulphate of iron in eight or ten of boiling water, and continue the mixture as long as any effervescence and precipitation ensues. Wash the precipitate several times with boiling water. It will have a green colour; but on the addition of a quantity of muriatic acid, equal to twice that of the sulphate of iron which has been used, it will assume a beautiful blue colour. Wash it again with water, and dry it in a gentle heat. In this state it is the pigment, called Prussian blue, which consists of a mixture of prussiate of iron with alumine. From prussiate of iron, the prussic acid may be separated by the following process: mix two ounces of red oxide of mercury, prepared by nitric acid, with four ounces of finely powdered Prussian blue, and boil the mixture with twelve ounces of water in a glass vessel, shaking frequently. Filter the solution, which is a prussiate of mercury, while hot, and when cool add to it in a bottle two ounces of iron filings, and six or seven drachms of sulphuric acid; shake these together, decant the clear liquor into a retort, and distill off one-fourth of the liquor. The distilled liquor is the prussic acid, which combines with alkalies and earths, and has many of the properties belonging to the other acids. It has a sweetish taste, and a smell resembling that of bitter almonds: it does not redden blue vegetable colours. It precipitates sulphurets, and curdles soap. It separates allumina from nitric acid. Oxygenized muriatic acid entirely decomposes it. It does not appear to have a strong affinity for alkalies, nor does it take them from carbonic acid, for no effervescence arises on adding it to a solution of alkaline carbonates; on the contrary, its combinations with alkalies and earths are decomposed by exposure to carbonic acid, even when highly diluted, as in atmospheric air. It readily combines, however, with pure alkalies, destroys their alkaline properties, and forms crystallizable salts. It does not precipitate iron blue, but green, and this green precipitate is soluble in acids. The rays of light render the green precipitate blue, as does also the addition of metallic iron, or sulphurous acid.

PRUSSIAN BLUE. See **PRUSSIC ACID**.

PRYTANEUM, in Grecian Antiquity, a large building in Athens, where the council of the prytanes or presidents of the senate assembled, and where those who had rendered any signal service were maintained at the public expense.

PSALTERIUM GEORGII, the *Harp of George*, is a new constellation, introduced by one of the German astronomers, in honour of his late Britannic Majesty George III. It is bounded on the north by Taurus, on the east by Sceptum Brandenburgium, on the south by Eridanus, and on the west by Cetus.

PSITTACUS, or **PARROT**, a genus belonging to the order of pica. The bill in this genus is hooked from the base; and the upper mandible is movable; the nostrils are round, placed

in the base of the bill, which in some species is furnished with a kind of cere; the tongue is broad, and blunt at one end; the head is large, and the crown flat; the legs are short, the toes placed two before and two behind. These abound within the tropics, and live on seeds and fruit, in their natural state, but in confinement will eat both flesh and fish. They often appear in flocks, yet are in such cases generally somewhat separated into pairs. They are noisy, mimetic, singularly capable of articulating human sounds, extremely docile, and long lived. They breed in the hollows of trees, without constructing any nest, and use their feet as hands to convey food to their mouths. Latham notices one hundred and thirty three species, and Gmelin no fewer than one hundred and sixty-nine. The general division is regulated by the evenness or unevenness of the tallo.

PTOLEMAIC, or *Ptolemean System of Astronomy*, is that invented by Claudius Ptolemaeus, a celebrated astronomer and mathematician of Pelusium in Egypt, who lived in the beginning of the second century of the Christian era. This hypothesis supposes the earth immovably fixed in the centre, of the universe, and that the sun, the moon, the planets, and stars, all move about it from east to west, once in twenty-four hours, in the order following, viz. the Moon next to the Earth, then Mercury, Venus, the Sun, Mars, Jupiter, Saturn, the fixed stars, the first and second crystalline heavens, and, above all, the action of their primum mobile.

PUDDING, a sea term, or **PUDDENING**, a thick wreath or circle of cordage, tapering from the middle towards the ends, pointed all over, and fastened about the main or fore masts of a ship, directly below the trusses, to prevent the yards from falling down, when the ropes by which they are usually suspended are shot away in battle. *Puddening* is also sometimes placed on a boat's stem as a kind of fender.

PUDDING STONE, in Chemistry, a term invented by English lapidaries to designate one particular mineral aggregate, consisting of oblong and rounded pebbles of flint, about the size of almonds, imbedded in a hard siliceous cement. The pebbles are usually black, and the cement of a light yellowish brown. It is capable of receiving a very high polish, and is used in ornamental works. It is found chiefly in Essex. The French mineralogists have naturalized the term *poudingue*, and have applied it to all rounded stones imbedded in a cement, so as to make it nearly synonymous to the English "rubble-stone."

PULEX, the *Flea*, a genus of insects of the order aptera.

PULLEY, one of the simple machines, or, as they are commonly called, *mechanical powers*; its theory is laid down under **MECHANICS**. The present article is introduced for the purpose of mentioning some ingenious practical combinations of pulleys, in addition to those already exhibited. The usual methods of arranging pulleys in their blocks may be reduced to two. The first consists in placing them one by the side of another upon the same pin: the other, in placing them directly under one another upon separate pins. Each of these methods, however, is liable to inconvenience; and Mr. Smeaton, to avoid the impediments to which these combinations are subject, proposes to combine these two methods in one. A very considerable improvement in the construction of pulleys has been made by James White, who obtained a patent for his invention, of which he gives the following description.—The annexed figure

10 G

shows the machine, consisting of two pulleys, Q and R, one fixed and the other moveable. Each of these has six concentric grooves capable of having a line put round them, and thus acting like as many different pulleys, having diameters equal to those of the grooves. Supposing then each of the grooves to be a distinct pulley, and that all their diameters were equal, it is evident that if the weight 144 were to be raised by pulling at S till the pulleys touch each other, the first pulley must receive the length of line as many times as there are parts of the line hanging between it and the lower pulley. In the present case there are twelve lines b, d, f, &c. hanging between the two pulleys, formed by its revolution about the six upper and

lower grooves. Hence, as much line must pass over the uppermost pulley as is equal to twelve times the distance of the two. But, from an inspection of the figure, it is plain that the second pulley cannot receive the full quantity of line by as much as is equal to the distance betwixt it and the first. In like manner, the third pulley receives less than the first by as much as is the distance between the first and third; and so on to the last, which receives only one twelfth of the whole: for this receives its share of line x from a fixed point in the upper frame, which gives it nothing; while all the others in the same frame receive the line partly by turning to meet it, and partly by the line coming to meet them. Supposing now these pulleys to be equal in size, and to move freely as the line determines them, it appears evident, from the nature of the system, that the number of their revolutions, and consequently their velocities, must be in proportion to the number of suspending parts that are between the fixed point above mentioned, and each pulley respectively. Thus the outermost pulley would go twelve times round in the time that the pulley under which the part x of the line, if equal to it, would revolve only once; and the intermediate times and velocities would be a series of arithmetical proportionals, of which, if the first number were 1, the last would always be equal to the whole number of terms. Since then the revolutions of equal and distinct pulleys are measured by their velocities, and that it is possible to find any proportion of velocity on a single body running on a centre, viz. by finding proportionate distances from that centre; it follows, that if the diameters of certain grooves in the same substance be exactly adapted to the above series, (the line itself being supposed inelastic, and of no magnitude,) the necessity of using several pulleys in each frame will be obviated, and with that some of the inconveniences to which the use of the pulley is liable. In the figure referred to, the coils of rope by which the weight is supported are represented by the lines a, b, c , &c.: a is the line of traction, commonly called the fall, which passes over and under the proper grooves, until it is fastened to the upper frame just above x . In practice, however, the grooves are not arithmetical proportionals, nor can they be so; for the diameter of the rope employed must in all cases be deducted from each term; without which the smaller grooves, to which the said diameter bears a larger proportion than to the larger ones, will tend to rise and fall faster than they, and thus introduce worse defects than those which they were intended to obviate. The principal advantage of this kind of pulley is, that it destroys lateral friction, and that kind of shaking motion which is so inconvenient in the common pulley. These pulleys, when well executed, apply to jacks and other machines of that nature with peculiar advantage, both as to the time of going and their own durability; and it is possible to produce a system of pulleys of this kind of six or eight parts only, and adapted to the pocket, which, by means of a skain of sewing silk, or a clue of common thread, will raise upwards of a hundred weight. The friction of the pulley is now reduced to almost nothing by Mr. Garnett's ingenious patent friction-rollers, which produce a great saving of labour and expense, as well as in the wear of the machine, both when applied to pulleys and to the axles of wheel-carriages. His general principle is this; between the axle and nave, or centre pin and box, a hollow space is left, to be filled up by solid equal rollers nearly touching each other. These are furnished with axles inserted into a circular ring at each end, by which their relative distances are preserved; and they are kept parallel by means of wires fastened to the rings between the rollers, and which are riveted to them.

PULO, is a general term for island on the coasts of Siam and the island of Sumatra, in the East Indies, and in the Eastern Indian Ocean.

PULSE, in the animal economy, denotes the beating or throbbing of the heart and arteries.

PUMICE STONE, or porous glasses. When the compact glasses are exposed to the heat of our furnaces, they emit a great number of air bubbles, which render them porous; such is the origin of pumice. It has the same base as compact glass. The texture is fibrous: the fibres have a silky lustre. Colours various; white, brown, yellow, black. Before the blow-pipe, they melt into a white enamel.

PUMP, a hydraulic machine for raising water by the pressure of the atmosphere. The most important and certain part of the theory of pumps has been laid down in the construction of two or three kinds which have been already described in this work, under the articles CENTRIFUGAL MACHINE, FIRE-ENGINE, FORCE-PUMP, and HYDRAULICS. A few other useful, yet not complex, pumps, will be described in the present article; and some account will be added of the most ingenious pistons and valves.

A modification of the sucking-pump which has been much recommended, is exhibited in the annexed figure. Here the

suction-pipe CO comes up through a cistern $KMNL$ deeper or longer than the intended stroke of the piston, and has a valve C at top. The piston, or what acts in lieu of it, is a tube $AHGR$, open at both ends, and of a diameter somewhat larger than that of the suction-pipe. The interval between them is filled up at HG by a ring or belt of soft leather, which is fastened to the outer tube, and moves up and down with it, sliding along the smoothly polished surface of the suction-pipe with very little friction. There is a valve I on the top of this piston, opening upwards. Water is poured into the outer cistern. The outer cylinder or piston being drawn up from the bottom, there is a great rarefaction of the air which was between them, and the atmosphere presses the water up through the suction-pipe to a certain height; for the valve I keeps shut by the pressure of the atmosphere and its own weight. Pushing down the piston causes the air, which had expanded from the suction-pipe into the piston, to escape through the valve I : drawing it up a second time allows the atmosphere to press more water into the suction-pipe, to fill it, and also part of the piston. When this is pushed down again, the water which had come through the valve C is now forced out through the valve I into the cistern $KMNL$, and now the whole is full of water. When, therefore, the piston is drawn up, the water follows, and fills it, if not thirty-three feet above the water in the cistern; and when it is pushed down again, the water which filled the piston is all thrown out into the cistern; and after this it delivers its full contents of water every stroke. The water in the cistern $KMNL$ effectually prevents the entrance of any air between the two pipes; so that a very moderate compression of the belt of soft leather at the mouth of the piston cylinder is sufficient to make all perfectly tight.

If a pump absolutely without friction be wanted, the following seems preferable for simplicity and performance to any we have seen, when made use of in proper situations. Let

NO , in the figure, be the surface of the water in the pit, and K the place of delivery. The pit must be as deep in water as from K to NO . $ABCD$ is a wooden trunk, round or square, open at both ends, and having a valve P at the bottom. The top of this trunk must be on a level with K , and has a small cistern $EADF$. It also communicates laterally with a rising pipe GHH , furnished with a valve at H opening upwards. LM is a beam of timber so fitted to the trunk as to fill it without sticking, and is of at least equal length. It hangs by a chain from a working beam, and is loaded on the top with weights exceeding that of the column of water which it displaces. Now suppose this beam allowed to descend from the position in which it is drawn in the figure; the water must rise all round it, in the crevice which is between it and the trunk, and also in the rising pipe; because the valve P shuts, and H opens; so that when the plunger has got to the bottom, the water will

stand at the level of K. When the plunger is again drawn up to the top by the action of the moving power, the water sinks again in the trunk, but not in the rising pipe, because it is stopped by the valve H. Then allowing the plunger to descend again, the water must again rise in the trunk to the level of K, and it must now flow out at K; and the quantity discharged will be equal to the part of the beam below the surface of the pit-water, deducting the quantity which fills the small space between the beam and the trunk. This quantity may be reduced almost to nothing, for if the inside of the trunk and the outside of the beam be made tapering, the beam may be let down till they exactly fit; and as this may be done in square work, a good workman can make it exceedingly accurate. But in this case, the lower half of the beam and trunk must not taper; and this part of the trunk must be of sufficient width round the beam to allow free passage into the rising pipe. Or, which is better, the rising pipe must branch off from the bottom of the trunk. A discharge may be made from the cistern E A D F, so that as little water as possible may descend along the trunk when the piston is raised.

There can be no doubt, that the above is a very ingenious contrivance, and that it fully answers every purpose to which it can be rendered applicable. Indeed, it may be asserted with safety, that among the numerous ramifications into which mechanism and the mechanic arts have been extended, scarcely any branch furnishes a greater variety than may be found in pump machinery. Under this article many combinations of power are presented to the reader; but several others, equally deserving of attention, are left unnoticed, lest the whole should become too extended. We have endeavoured to select from the field of diversity such specimens, as display in the powers of invention the greatest portion of originality. Among these, pumps that are constructed to accomplish the desired end, either without friction, or with its aggregate greatly diminished, imperiously claim an admission into the pages of our scientific miscellany.

The most ingenious contrivance of a pump without friction is that of Haskins, described in Phil. Trans. No. 370, and called by him the *Quicksilver Pump*. Its construction and mode of operation are complicated; but the following preliminary observations will, we hope render them abundantly plain.

Let there be (see fig.) a cylindrical iron pipe, about six feet long, open at top; also another cylinder, connected with it at bottom, and of smaller diameter. It may either be solid, or, if hollow, it must be close at top. Let a third iron cylinder, of an intermediate diameter, be made to move up and down between the other two without touching either, but with as little interval as possible. This middle cylinder communicates by means of the pipe A B, with the upright pipe F E, having valves C and D (both opening upwards) adjoining to the pipe of communication. Suppose the outer cylinder suspended by chains from the end of a working beam, and let mercury be poured into the interval between the three cylinders till it fills the space to about three-fourths of their height. Also suppose that the lower end of the pipe F E is immersed into a cistern of water, and that the valve D is less than 33 feet above the surface of this water.

Now, suppose a perforation made somewhere in the pipe A B, and a communication made with an air-pump. When the air-pump is worked, the air contained in C E, in A B, and in the space between the inner and middle cylinders, is rarified, and is abstracted by the air-pump; for the valve D immediately shuts. The pressure of the atmosphere will cause the water to rise in the pipe C E, and will cause the mercury to rise between the inner and middle cylinders, and sink between the outer and middle cylinders. Let us suppose mercury 12 times heavier than water; then for every foot that the water rises in E C, the level between the outside and inside mercury will vary an inch; and if we suppose D E to be 50 feet then if we can rarify the air so as to raise the water to D

the outside mercury will be depressed to q and r , and the inside mercury will have risen to s , t , $s q$, and $t r$, being about 30 inches. In this state of things, the water will run over by the pipe B A, and every thing will remain nearly in this position. The columns of water and mercury balance each other, and balance the pressure of the atmosphere. While things are in this state of equilibrium, if we allow the cylinders to descend a little, the water will rise in the pipe F E, which we may now consider as a suction pipe; for by his motion the capacity of the whole is enlarged, and therefore the pressure of the atmosphere will still keep it full, and the situation of the mercury will again be in equilibrio. It will be a little lower in the inside space, and higher in the outside.

Taking this view of things, we see clearly how the water is supported by the atmosphere at a very considerable height. The apparatus is analogous to a syphon which has one leg filled with water and the other with mercury. But it was not necessary to employ an air-pump to fill it. Suppose it again empty, and all the valves shut by their own weight. Let the cylinders descend a little. The capacity of the spaces below the valve D is enlarged, and therefore the included air is rarefied, and some of the air in the pipe C E must diffuse itself into the space quilted by the inner cylinder. Therefore the atmosphere will press some water up the pipe F E, and some mercury into the inner space between the cylinders. When the cylinders are raised again, the air which came from the pipe C E would return into it again, but is prevented by the valve C. Raising the cylinders to their former height would compress this air; it therefore lifts the valve D, and escapes. Another depression of the cylinders will have a similar effect. The water will rise higher in F E, and the mercury in the inner space; and then after repeated strokes the water will pass the valve C, and fill the whole apparatus, as the air-pump had caused it to do before.

The position of the cylinders when things are in this situation is represented in this figure, the outer and inner cylinder in their lowest position having descended about 30 inches. The mercury in the outer space stands at q and r , a little above the middle of the cylinders, and the mercury in the inner space is near the top t of the inner cylinder. Now let the cylinders be drawn up. The water above the mercury cannot get back again through the valve C, which shuts by its own weight. We therefore attempt to compress it; but the mercury yields, and descends in the inner space, and rises in the outer till both are quickly on a level, about the height uv . If we continue to raise the cylinders, the compression forces out more mercury, and it now stands lower in the inner than in the outer space. But that there may be something to balance this inequality of the mercurial columns, the water goes through the valve D, and the equilibrium is restored when the height of the water in the pipe E D above the surface of the internal mercury is twelve times the difference of the mercurial columns (on the former supposition of specific gravity). If the quantity of water be such as to rise two feet in the pipe E D, the mercury in the outer space will be two inches higher than that in the inner space. Another depression of the cylinders will again enlarge the space within the apparatus, the mercury will take the position of the last figure, and more water will come in. Raising the cylinders will send this water four feet up the pipe E D, and the mercury will be four inches higher in the inner than in the outer space. Repeating this operation, the water will be raised still higher in D E; and this will go on till the mercury in the outer space reaches the top of the cylinder: and this is the limit of the performance. The dimensions with which we set out will enable the machine to raise the water about 30 feet in the pipe E D; which, added to the 30 feet of C F, makes the whole height above the pit water 60 feet. By making the cylinders longer we increase the height of F D. This machine must be worked with great attention, and but slowly; for at the beginning of the forcing stroke the mercury very rapidly sinks in the inner space and rises in the outer, and will dash out and be lost. To prevent this as much as possible, the outer cylinder terminates in a sort of cup or dish, and the inner cylinder should be tapered at the top.

A Quicksilver Pump has been lately contrived by a Mr. Clarke of Edinburgh, for the purpose of raising water without friction, and in its construction is essentially different from that of Mr. Haskins, having great power in drawing and forcing water to any height, and possessing extreme simplicity in its construction.

a a is the main pipe inserted into the well *b*; a valve is situated at *c*, and another at *d*, both opening upwards; a piece of iron tube is then bent into a circular form, as at *f*, again turned off at *g* in an angular direction, so as to pass through a stuffing box at *h*, and from thence bent outwards as at *i*, connecting itself with the ring. A quantity of quicksilver is then put into the ring filling it from *g* to *g*, and the ring being made to vibrate upon its axis *h*, a vacuum is effected in the main pipe by the recession of the mercury from *g* to *i*, thereby causing the water to rise and fill the vacuum; upon the motion being reversed, the quicksilver slides back to *g*, forces up the water, and expels it at the spout *e*. Mr. Clark calculates that a pump of this description with a ring twelve feet in diameter, will raise water the same height as the common lifting pump, and force it one hundred and fifty feet higher without any friction.

The following pump, without friction, may be constructed in a variety of ways by any common carpenter, without the assistance of the pump-maker, or plumber, and will be very effective for raising a great quantity of water to small heights, as in draining marshes, marl pits, quarries, &c. or even for the service of a house.

A B C D in this figure is a square trunk of carpenter's work open at both ends, and having a little cistern and spout at top. Near the bottom there is a partition made of board, perforated with a hole B, and covered with a clack. *f f f f* represent a long cylindrical bag made of leather or of double canvass, with a fold of thin leather, such as sheep-skin, between the canvass bags. This is firmly nailed to the board E with soft leather between. The upper end of this bag is fixed on a round board having a hole and valve F. This board may be turned in the lathe with a groove round its edge, and the bag fastened to it by a cord bound tight round it. The fork of the piston rod F G is firmly fixed into this board; the bag is kept distended by a number of wooden hoops or rings of strong wire *f f f f*, &c. put into it at a few inches' distance from each other. It will be proper to connect these hoops before putting them in, by three or four cords from top to bottom, which will keep them at their proper distances. Thus will the bag have the form of a barber's bellows powder-puff. The distance between the hoops should be about twice the breadth of the rim of the wooden ring to which the upper valve and piston rod are fixed. Now let this trunk be immersed in the water. It is evident that if the bag be stretched from the compressed form which its own weight will give it by drawing up the piston rod, its capacity will be enlarged, the valve F will be shut by its own weight, the air in the bag will be rarefied, and the atmosphere will press the water into the bag. When the rod is thrust down again, this water will come out by the valve F, and fill part of the trunk. A repetition of the operation will have a similar effect; the trunk

will be filled, and the water will at last be discharged by the spout. —The same bag-piston may be employed for a forcing pump, by placing it below the partition, and inverting the valve; and it will then be equally strong, because the resistance in this case too will act by compression.

Single Barrel Pump, with a Double Action.—An ingenious variation in the construction of the sucking pump, is that with two piston rods in the same barrel, invented by the late W. Taylor, of Southampton. A vertical section of this pump

is given in the figure. The piston rods have racks at their upper parts working on the opposite sides of a pinion, and kept in their proper positions by friction rollers. The valves used in this pump are of three kinds, as shown at *a*, *b*, and *c*. The former is a spheric segment which slides up and down on the piston rod, and is brought down by its own weight; the second, *b*, is called the pendulum valve; and the third, *c*, is a globe which is raised by the rising water, and falls again by its own weight. Each of these valves will discharge itself from chips, sand, gravel, &c. brought up by the water. In this kind of pump the piston may either be put in motion by a handle in the usual way, or a rope may pass round the wheel *d* in a proper groove, the two ends of which, after crossing at the lower part of the wheel, may be pulled by one man or more,

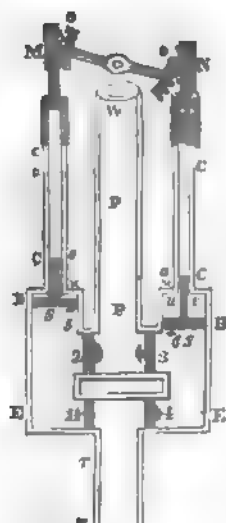

on each side. A pump of this kind, with a seven-inch bore, heaves a ton twenty-four feet high in a minute, with ten men, five only working at a time on each side.

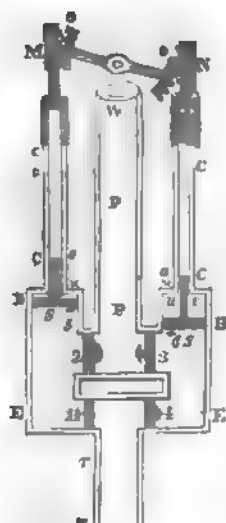

Another improvement of the common pump has been made by Todd, of Hall. This invention, in some particulars, bears a resemblance to the ordinary one, but he has contrived to double its powers by the following means:—Having prepared the piston cylinder, which may be twelve feet high, he cuts from the bottom thereof about three feet; at the end of the great cylinder he places an atmospheric valve, and to the top of the small cylinder a serving valve. In the bottom of the small cylinder, which contains the serving valve, is inserted an oblong elliptical curved tube, of equal calibre with the principal cylinder, and the other end is again inserted in the top of the great cylinder. This tube is divided in the same manner as the first cylinder, with atmospheric and serving valves, exactly parallel to the valves of the first cylinder. The pump, thus having double valves, produces double effects, which effects may be still further increased by extending the dimensions. This pump, in addition to its increased powers, possesses another very great and prominent advantage. By screwing to it the long leather tube and fire-pipe of the common engine, it is in a few minutes converted into an effective fire-engine. Hence, whoever possesses one, may be said to have a convenient domestic apparatus against fire. Three men can work it; one to turn the winch, another to direct the fire-pipe, and a third to supply the water.

The late Mr. Benjamin Martin invented a curious and powerful pump with two pistons, the friction of which was exceedingly small. An admirable engraving of this pump, by Lowry, is given in vol. xx. of Tilloch's Philosophical Magazine.

The following is a plan of a Gold Mine Pump, which will supersede the necessity of cutting new shafts, to suit the wind-

and various elevations and declinations of the mines. We have been informed, that in the gold and silver mines in South America, the rod pump is often rendered useless, from the want of such contrivance.

Description.—*rr* represent a pipe entering the well, and is supplied with water by means of the pressing of the atmosphere; *BBB* are two working barrels; *PP*, the pipe; *CCCC* are half-inch pipes filled with water; *oo* the work-

eam, that acts on the pistons that work on the half-inch pipes; *s* are buckets; *ev*, evacuator. If small quantity of water issue into

vacuants, the piston blocks, *xx*, it back through the valves *5, 6*; numbers 1, 2, 3, 4, represent the valves.
 Perhaps a rough calculation would be the best mode of elucidating the principle of this invention. Let us suppose the depth of the pipes *CP* to be 30 feet, the barrels four feet, and the pipes *rr* 16 feet; the diameter of the wide one to be 20 inches, except that the pipes *CCCC*, which is half an inch, weighs 30 pounds; the pressure on the buckets *SS* is equal to 1500 pounds each; so that at the rising of the piston *M*, the pressure of the atmosphere, 1500 pounds, will force the bucket *S* up, so that the water will keep rising with the piston *M*, at the same time the piston *N* will be forcing the water downwards. The water will, in sequence, force the bucket *s*, so that the water in the pipe is forced out through the valve 3, into the pipe *PP*, and *W*. Now, it is easily to be perceived, that an evacuation will be created at *s*; that afterwards the piston *N* will be forced up, and the effect will be as described of *M*, and the effect will be as described of *N*, and so on alternately, so that a continuous stream will flow out at *W*. The pressure of 1500 pounds forced in consequence of the buckets *SS* being 20 feet above the level of the water; so that there is left five pounds on every inch, which multiplied by 300 inches, the area of the piston, gives 1500 pounds.—The advantage of this pump is that, as, whatever the winding of the mines might be, the effect of such a pump might be turned accordingly, without any addition to the pump, and all the expense of cutting new shafts would thus be saved.

The annexed figure represents a Pump, described by M. Mariotte in his *Idées Méthodiques et Physiques*, which is superior to the pumps now in use. Its action and operation may be easily understood by inspection. *A* is the working cylinder; *B*, the piston, or plunger, the rod of which, works in an air-tight manner, through the stuffing box *C*. *E* is the suction pipe, leading from the well; and *H*, the rising pipe. *FF* and *GG* are valves, opening upwards. The piston is represented as ascending, and therefore the valves *FF* are open, and at *GG* shut. A plate closing the bottom of the cylinder, and by which the whole may be easily bolted down to the work support.

It will easily be seen, that this pump works water both in the ascending and descending stroke of the piston, and therefore affords a continued stream of water. As with double action have been in use some time, but the one now described is simple and powerful than those on the usual construction.

The Atmospheric Pump.—This figure represents a pump for raising water from wells between 50 and 60 feet in depth, worked merely by a lever. Let *A* represent a cylinder

three feet in diameter, and 30 in length, reaching below the surface of the water in the well, furnished with an aperture *B* at the top, *C* a cylinder about eight inches in diameter, with an aperture at *D*. Let *E* represent an air-tight valve, alternately to open and close the two apertures *B* and *D*. *F*, a valve that will open and close itself by the pressure of the atmosphere. *G*, the handle to be used by the operator for opening and closing the apertures *B* and *D*.

When we wish to work the pump, the aperture *B* must, in the first instance, be closed, and *D* of course will remain open, to allow the whole of the air in the large cylinder to escape, that the water may follow; we then make use of the handle, and the exterior pressure of the atmosphere will raise the water to the height of 30 feet, as in the common atmospheric pump, the valve *F* will then be closed, and 10 feet of the water in the wide cylinder, retained 20 feet above that in the well; then by opening the aperture *B*, we

allow the atmospheric pressure to enter, at the same time pressing the valve *E* against the aperture *D*, making it air-tight, and keeping it in that position, we are enabled, by the continued action of the piston, to raise that ten feet of water another thirty feet from its surface in the large cylinder, which will make fifty feet from its surface in the well. Again, by closing the aperture *B*, we repeat the operation in the same manner as before described. But if we were to have the narrow cylinder fixed at five feet down the wide one, we should then be enabled to raise the water fifty-five feet from its surface in the well. We are then enabled to raise water from wells between 50 and 60 feet in depth, not by a multiplication of pumps and cisterns, but by employing the atmospheric pressure double, or at two parts of the same pump. Instead of having the wide cylinder *A* to reach below the surface of the water in the well, it will be only requisite to have it as far down as the part where the valve *F* is situated. And it will be better to employ a small suction pipe from beneath the valve *F*, to the water in the well, which will produce the same effect more perfectly, and in a much shorter space of time.

The **Triple Pump**, a sketch of which is given in the following engraving, is taken from Bockler's *Theatrum Machinarum*. The nature of the machinery by which this pump is worked, will be sufficiently obvious to any person after an inspection of the figure. The horizontal wheel *C*, and its shaft *A*, are turned by the capstan bars *B*; this wheel drives the pinion *D*, on the axle of which is the equalizing fly *E*, and the crank *F*: the rotatory motion of the crank alternately raises and depresses the bar *G*, with the lever *H* turning on a roller and pivots, and thus works the pump *I*: at the same time the connecting rods *K* move in like manner the lever *M*, and work the pump *O*; and the rods *L* move the lever *N*, and work the pump *P*. If the levers *H*, *M*, *N*, are not so contrived that the extremities of each shall move through equal spaces, the bores of *I*, *O*, and *P*, must be made in the inverse ratio of those spaces, otherwise one or other of the reservoirs may be drawn dry; a defect that should be carefully guarded against.

Our attention may now be directed to some of the different forms which may be given to the pistons and valves of a pump. The great desideratum in a piston is, that while it be as tight as possible, it should have as little friction as is consistent with this indispensable quality. The common form, when carefully executed, possesses these properties in an eminent degree. This piston is a sort of truncated cone, generally made of wood not apt to split, such as elm or beech. The small end of it is cut off at the sides, so as to form a sort of arch, by which it is fastened to the iron rod or spear. The two ends of the conical

part may be hooped with brass. This cone has its larger end surrounded with a ring or band of strong leather fastened with nails, or by a copper hoop, which is driven on it at the smaller end; the further this end reaches beyond the base of the cone, the better; and the whole must be of uniform thickness all round, so as to suffer equal compression between the cone and working barrel. The seam or joint of the two ends of this band

must be made very close; but not sewed or stitched together, as that would occasion bumps or inequalities, which would spoil its tightness; and no harm can result from the want of it, because the two edges will be squeezed close together by the compression in the barrel. Nor is it by any means necessary that this compression be great: this is a very detrimental error of the pump-makers. It occasions enormous friction, and destroys the very purpose which they have in view, viz. rendering the piston air-tight; for it causes the leather to wear through very soon at the edge of the cone, and it also wears the working barrel.

Belidor, an author of the first reputation, has given the description of a piston which he highly extols, and is undoubtedly a very good one, constructed from principle, and extremely well composed. It consists of a hollow cylinder of metal (fig. 1.) pierced with a number of holes, EE, FF, having at top a flanch, whose diameter is nearly equal to that of the working barrel of the pump Q N. This flanch has a groove round it. There is another flanch below, by which this hollow cylinder is fastened with bolts to the lower end of the piston, represented in fig. 2. This consists of a plate with a grooved edge similar to A B, and an intermediate plate which forms the seat of the valve. The composition of this part is better understood by inspecting the figure than by any description. The piston-rod H is fixed to the upper plate by bolts through its different branches at G O. This metal body is then covered with a cylindrical bag of leather, fastened on

Fig. 1.

Fig. 2.

it by cords bound round it, filling up the grooves in the upper and lower plates. The operation of the piston is as follows:—A little water is poured into the pump, which gets past the sides of the piston, and lodges below in the fixed valve. The piston being pushed down, dips into this water, and it gets into it by the valve. But as the piston in descending compresses the air below it, this compressed air also gets into the inside of the piston, swells out the bag which surrounds it, and compresses it to the sides of the working-barrel. When the piston is drawn up again, it must remain tight, because the valve will shut and keep in the air in its most compressed state; therefore the piston must perform well during the suction. It must act equally well when pushed down again, and act as a *forcer*; for, however great the resistance may be, it will affect the air within the piston to the same degree, and keep the leather close applied to the barrel.

The following piston is also ingenious, and has a good deal of merit. O P P O, in the figure, is

the box of the piston, having a perforation Q, covered above with a flat valve K, which rests in a metal plate that forms the top of the box. ABCBA is a stirrup of iron to which the box is fixed by screws $\alpha, \alpha, \alpha, \alpha$, whose heads are sunk in the wood. This stirrup is perforated at C, to receive the end of the piston-rod, and a nut H is screwed on below to keep it fast. DEFED is another stirrup, whose lower part at DD forms a hoop like the sole of a stirrup, which embraces a small part of the top of the wooden box. The lower end of the piston-rod is screwed; and before it is put into the holes of the two stirrups (through which holes it slides freely) a broad nut G is screwed on it. It is then put into the holes, and the nut H firmly screwed up. The packing RR is then wound about the piston as tight as possible till it completely fills the working-barrel of the pump. When long use has rendered it in any degree loose, it may be tightened again by screwing down the nut G. This causes the ring DD to compress the packing between it and the projecting shoulder of the box at PP; and thus causes it to swell out, and apply itself closely to the barrel. Prony, in his *Architecture Hydraulique*, ascribes this invention to M. Bettancourt.

We shall add only another form of a perforated piston; which being on a principle different from all the preceding, will suggest many others; each of which will have its peculiar advantages. O O, in the figure, represents

the box of this piston, fitted to the working-barrel in any of the preceding ways as may be thought best. A B is a cross-bar of four arms, which is fixed to the top of the box. C F is the piston-rod going through a hole in the middle of A B, and reaching a little way beyond the bottom of the box. It has a shoulder D, which prevents its going too far through. On the lower end there is a thick metal plate, turned conical on its upper side, so as to fit a conical seat P P in the bottom of the piston-box. When the piston-rod is pushed down, the friction on the barrel prevents the box from immediately yielding. The rod therefore slips through the hole of the cross-bars A B. The plate E, therefore, detaches itself from the box. When the shoulder D presses on the bar A B, the box must yield, and be pushed down the barrels, and the water gets up through the perforation. When the piston-rod is drawn up again, the box does not move till the plate E lodges in the seat P P, and thus shuts the water-

way; and then the piston lifts the water which is above it, and acts as the piston of a sucking-pump. This is a very simple and effective construction, and makes a very tight valve. It has been much recommended by engineers of the first reputation, and is frequently used; and, from its simplicity, and the great solidity of which it is capable, it seems very fit for great works. But it is evident that the water-way is limited to less than one-half of the area of the working-barrel. For if the perforation of the piston be one-half of the area, the diameter of the plate or ball EF must be greater; and therefore less than half the area will be left for the passage of the water by its sides.

We come now to consider briefly the forms which may be given to the valves of an hydraulic engine. The requisites of a valve are, that it shall be tight, of sufficient strength to resist the great pressures to which it is exposed, that it afford a sufficient passage for the water, and that it do not allow much to go back while it is shutting. Some engineers make their great valves of a pyramidal form, consisting of four clacks, whose hinges are in the circumference of the water-way, and which meet with their points in the middle, and are supported by four ribs which rise up from the sides, and unite in the middle. This is an excellent form, affording the most spacious water-way, and shutting very readily. It seems to be the best possible for a piston. The rod of the piston is branched out on four sides, and the branches go through the piston-box, and are fastened below with screws. These branches form the support for the four clacks. We have seen a valve of this form in a pump of six feet diameter, which discharged twenty hogsheads of water every stroke, and made twelve strokes in a minute, raising the water above twenty-two feet.

There is another form of valve, called the *button* or *tail valve*. It consists of a plate of metal AB (see the figure) turned conical, so as exactly to fit the conical cavity *bb* of its box. A tail CD projects from the under side, which passes through a cross-bar EF in the bottom of the box, and has a little knob at the end, to hinder the valve from rising too high. This valve, when nicely made, is unexceptionable. It has great strength, and is therefore proper for all severe strains, and it may be made perfectly tight by grinding. Accordingly it is used in all cases where this is of indispensable consequence. It is most durable, and the only kind that will do for passages where steam or hot water is to go through. Its only imperfection is a small water-way; which, from what has been said, cannot exceed, nor indeed equal, one-half of the area of the pipe. If we endeavour to enlarge the water-way, by giving the cone very little taper, the valve frequently sticks so fast in the seat that no force can detach them. And this sometimes happens during the working of the machine; and the jolts and blows given to the machine in taking it to pieces, in order to discover what has been the reason that it has discharged no water, frequently detaches the valve, and we find it quite loose, and cannot tell what has deranged the pump. When this is guarded against, and the diminution of the water-way is not of very great consequence, this is the best form of a valve.

Analogous to this is the simplest of all valves. It is nothing more than a sphere of metal, to which is fitted a seat with a small portion of a spherical cavity. Nothing can be more effectual than this valve; it always falls into its proper place, and in every position fits it exactly. Its only imperfection is the great diminution of the water-way. If the diameter of the sphere do not considerably exceed that of the hole, the touching parts have very little taper, and it is very apt to stick fast. It opposes much less resistance to the passage of the water than the flat under-surface of the button valve. The spherical valve must not be made too light, otherwise it will be hurried up by the water, and much may go back while it is returning to its place.

Description of an Improved Pump for Draining, constructed by Henry W. Revely, Esq. Civil Engineer, 33, King-street, West, Bryanstone-square, London.—The principal objects in the construction of this pump, are the following: "To obtain a

machine of large dimensions, and of easy transportance; to afford sufficient scope for the most advantageous application of the united strength of many men, in raising large bodies of water to moderate heights, as required in draining large tracts of land, sinking foundations, &c. &c. To prevent, as far as possible, the choking, and final destruction, of the principal parts of the machine, by the impurities with which water, under such circumstances, is always loaded."

Explanation of the Drawing. (See Plate *Pump for Draining*.)—Fig. 1. Front elevation of the whole machine. *a, a*, the framework usually constructed of wood. *c, c*, the levers and hand-rails, by which the pumps are worked, as in the common fire-engine. *m, m*, two stages, or platforms, on which the men stand. *h, h*, the suction pipe, which branches out into two, at the upper part, in order to supply both the cylinders. This pipe is divided into short lengths by screw-joints, to suit various depths. *d, d*, the double rising-pipe, which communicates with the large cistern, or general receiver. *x, x*, the cistern, or general receiver, to which the rising-pipe, and pump cylinders, are firmly united. *f*, the delivering spout.

N. B. The same letters refer to the same parts in all the figures.

Fig. 2. A side section, shewing the internal construction of the whole. *o*, the suction valve. *p*, the rising valve. *r*, a small copper spring placed behind the rising-valve, in order to ensure its closing rapidly.

Observation.—The valves and their seats are of an oblong rectangular form, and are made entirely of metal, without any fitting whatsoever, so that they can never be out of order.

Fig. 3. A back view, with a section of one of the cylinders. *s, t*, the pump-arms, with their pistons attached in the common way.

Fig. 4. A side view. *n, n*, the spindle, to which the working levers and pump-arms are attached. *e*, one of the cylinders, or pump-barrels, which rise a few inches above the bottom of the cistern, to a sufficient height to prevent the dirt and stones, accumulated in the latter, from falling in, but not so high as to hinder the clear water from flowing into them, and keeping their pistons free and air-tight. *g*, a man-hole, through which, when necessary, the valves may be cleaned and examined. *q*, a plug, used for the double purpose of discharging the pump of its water, and cleaning the belly-part, from time to time, of the sand and gravel which are deposited there during the working.

Fig. 5. Is a plan of the whole machine, with its levers and hand-rails ready for work.

General Observations.—It is evident from this construction, that the water which is pumped up does not pass through the cylinders; it cannot, therefore, although loaded with sand and gravel, injure them in any sensible degree. The pistons, however, are constantly working between two waters, and remain perfectly free and air-tight. The machine, represented by this drawing, has the barrels of its pumps of the internal diameter of fourteen inches, and the length of each arm of its levers, eight feet. By placing six men outside, and four men within each hand-rail, the united strength of twenty men, acting at the extremity of a long lever, may be applied to working this pump; but in ordinary cases, where such an exertion is not requisite, half that number will be sufficient. The quantity of water raised by this pump, will vary according to the depth from which it is to be raised, and the power applied. It may be considered, however, in general, to raise from 2000 to 3000 cubic feet per hour.

Description of a new and efficient Hydropneumatic Pump for the Compression of Gases.—Lamps for condensed gas, are found so convenient and manageable in every respect, and oil-gas applied to the purpose of illumination is so preferable on various accounts to that made from pit-coal, that they are daily coming more and more into use. Independently of their adoption by private families, they are now employed in many shops, where the goods are of a nature to be injured by sulphurized hydrogen (always present in coal-gas,) and their use is extending among public institutions and large establishments about Town. New-gate has, for some months, been regularly lighted by means of portable gas lamps.

The establishment of the Portable Gas Companies was at first viewed in a dubious light, but time and experience have so

far removed suspicion, that they now receive ample patronage. To render their establishment complete, there was nothing wanted, with the lamp, but such a condensing pump as we are now about to lay before our readers.

In consequence of the general use to which gas is likely to be brought when highly compressed, it becomes important to ascertain the best method of reducing it to that state, so that it shall be most useful and advantageous to the public. The present method of compressing gas is attended with a great many disadvantages; these principally consist of a considerable loss of gas during the operation of compression, an immense loss of power in consequence of the gas not being completely forced out of the pump barrel, and the excessive wear and tear of the machinery employed therein.

The pump which has hitherto been used for this purpose consists of a barrel well bored out, open at one end, as A, fig. 1. see plate *Hydro-Pneumatic Pump*, and *Bute's Furnace*,) with the two valves *c* and *d* at the other end; and the solid piston B working therein. This is, perhaps, the best possible arrangement of the piston pump, and is the one adopted by some of the first engineers and machinists.

Now, in the use of this pump it is impossible that the piston can be worked so close as to strike the bottom; there must be some space for clearance, otherwise there would be great danger of damaging the valves, or doing other mischief. Say, in a pump of 12-inch stroke and 5 inches' diameter, the spaces allowed between the bottom of the piston and the bottom of the pump shall be one-eighth of an inch, which is no great deal; now as the operation of compression goes on, this space will be gradually increased, and when the gas arrives at a pressure of 30 atmospheres, or 550 lbs. upon the square inch, (which is the average pressure employed by the Portable Gas Company,) there will then be the enormous weight of 9000 lbs. acting against the bottom of the barrel and the piston, which will naturally cause them to recede the one from the other; and from the actual spring of the cranks, the looseness and wear of bearings, spring of the connecting rods and crossheads, and even of the bottom of the pump itself, we may fairly conclude that under this great pressure the piston does not come within $\frac{1}{4}$ of an inch of the bottom; consequently there remains that quantity of gas under the great pressure of 30 atmospheres, which cannot be forced out, and which, as the piston recedes for the return stroke, will expand in the barrel, and occupy a great part of the space; thereby preventing the admission of another full charge. And this is one of the greatest defects of this sort of pump; for allowing the space to be one quarter of an inch, it will be just one forty-eighth of the whole capacity of the pump; and adding to this the space left by the rising of the eduction valve *d*, which will remain open until the piston has receded a little in the return stroke, we may doubtless presume that a portion of compressed gas, equal in volume to one-fortieth of the whole stroke of the pump, remains behind every time in the barrel; therefore when the pump commences working, and the gas in the receiver arrives at a pressure of 10 atmospheres only, three fourths of the gas is forced out of the barrel,—at 20 atmospheres, one half,—at 30 atmospheres, one quarter;—and when it arrives at 40 atmospheres, the pump will cease to act, as the compressed gas which remains will expand itself, and fill the whole barrel; and therefore no more gas can then be admitted from the gasometer. Moreover, there is an actual loss of gas occasioned by the leaking of the piston, which is a failing that these pumps are more or less liable to; for, whether they be packed with metallic rings, cupped leathers, or hemp packing, still there will be some escape under this great pressure; and if the leathers, &c. are screwed up so hard as totally to prevent the escape of the gas, the friction will become immense, consequently one half of the power will be absorbed, and thus very little advantage would be gained by the remedy.

These observations will, it is presumed, place the defective operation of the common forcing pump in a clear point of view, and will naturally lead us to comprehend the advantages of the hydro-pneumatic pump. It will have been observed, that the great evil in the common pump is the space or cavity that is left when the piston is down at the bottom of the stroke. Now the remedying of such evil is the primary object sought for in this improvement; for this purpose a quantity of non-elastic

fluid is introduced into the chamber of the pump, which, filling up the whole of the cavity when the piston is down, necessarily forces out every particle of the compressed gas; the method of accomplishing which will be readily understood in the description of the new pump.

Fig. 2 is an elevation, and fig. 3 a plan of the hydro-pneumatic pump. A A is a frame for supporting the machine; the pump consists of two chambers B and D; in the chamber B works the solid plunger C, through a cupped leather *e*, by means of the crank *n*, and the slings *m m*. D is the pneumatic chamber, at the top of which are placed the induction valve *c* and the eduction valve *e*: over the latter is placed a small vessel *g* with the pipe *h* leading to the receiver.

Now when the plunger C is at the bottom of the stroke as shewn in fig. 2, the pneumatic chamber D is then to be quite full of oil, or some other non-elastic fluid: and for further security, a small quantity of oil is also to be above the eduction valve *e*; when the plunger C is drawn back the oil in the chamber D will sink to the level of *r s*, and the space will then be filled with the gas, which will rush from the gasometer through the pipe *f* and valve *e*; but when the plunger is again forced down, the oil will rise to the same height as before, again filling up the whole capacity of the chamber D, and forcing out every particle of gas through the valve *c*; and so on alternately:

If, through the increased pressure, or from some other cause, the oil in the chamber D should not be quite sufficient to fill up the whole cavity on the return of the plunger, it is of no consequence, because the moment the valve *c* rises ever so little, the oil which was above the valve will descend, and displace the gas in the chamber D. The vessel *g* is a small reservoir for the oil, and to receive any drainage from the gas; the tube *h* is for ascertaining that the proper quantity of oil is in the apparatus, or for supplying more when required. It is possible that a trifling leak may take place through the valve *c*; but this will be of little consequence, as the escape of a small quantity of a non-elastic fluid back into the chamber D is not attended with the twentieth part of the inconvenience to which the escape of the same volume of compressed gas would be subject. Now, the particular advantage of this pump is, that the full charge of gas is forced through the valve *c* at every stroke of the piston, whether the pressure be equal to 1, 10, or 50 atmospheres. Indeed, there are no limits to the degree of compression of which this pump is capable; provided the parts of the machine be sufficiently strong to withstand the strain, and an adequate power be employed; while it is supposed that the operation of the common pump is not capable of extending beyond a pressure of 30 or 40 atmospheres.

A diagram may be constructed, which will furnish an easy method of ascertaining the power required to work the above pump sufficiently near for all practical purposes.

Thus let a straight line AB be divided into 32 equal parts, of which make GB = 16; FG = 8; EF = 4; DE = 2; CD = 1; and AC = 1. Then if we consider this whole line equal to the space which the plunger moves over in one stroke of the pump, it is plain that at B, the commencement of the stroke, the stroke will be equal to one atmosphere only, represented by a vertical line Bb; but when the plunger has reached G, it will have made half a stroke, and the stroke will then be equal to two atmospheres, as shewn by a line Gg = 2 × Bb. Again, when the plunger is at F, it will have made three-quarters of the stroke, and the force will then be equal to four atmospheres = Ff = 4 Bb; and so on until the plunger arrives at C, when it will have made $\frac{31}{32}$ part of the stroke, and the compression and force will then be equal to 32 atmospheres, equal to a line Cc = 32 × Bb. Therefore, if we consider *bg, gf, fe, &c.* as so many straight lines, then will the areas Gb, Fg, Ef, Dc, &c. be nearly as the momenta of the plunger passing over the several spaces BG, GF, FE, &c. But the several areas Gb, Fg, Ef, &c. are all equal to each other; therefore the whole of the momenta of the plunger passing through the space BC, will be equal to five times the area GgB; that

$$\text{is, equal to } 5 \times \frac{gG + Bb \times GB}{2} = 5 \times \frac{1}{2} \times 16 = 120.$$

To this must now be added the momenta of the plunger passing from C to A, the last $\frac{1}{32}$ part of the stroke, which will be

$\times 1 = 32$; * which added to the above gives 162. We have to deduct the pressure of one atmosphere, which has acted on the plunger in passing over the space B A; that is 32×1 , which taken from the foregoing quantity will leave 120 a whole absolute momenta of the plunger. Now, divide quantity by the number of parts in the line A B ($= 32$), and I give $3\frac{1}{2}$ atmospheres, or $56\frac{1}{2}$ lbs. per square inch for the force on the plunger during the whole stroke, when raising gas equal to 32 atmospheres. Therefore as the gas acts but singly, if a fly-wheel of sufficient weight be employed, a power equal to about 30 lbs. on every square inch of plunger will be nearly adequate to the working of the pump. Gas of the pressure of only 20, or any other number of spheres less than 32, be required, the necessary average power for producing it can readily be ascertained from the diagram; for let the line A m represent the proposed area, then cutting off the upper part of the figure by the line n, parallel to the base A B; and calculating the remaining area in the manner already described, it will give the required power. And if the pressure should be required to be less than 32 atmospheres, then by increasing the height of the area towards a c in the manner already shewn, we can also estimate nearly the necessary required power.

Hand-Pump, a moveable pump, to put over the bows or side of a ship. These were formerly used in the navy, to pump water into the ship for washing the decks, &c. but since the invention of a cistern in the well, they are quite disused. **Brake**, the wooden lever or handle by which a pump is worked. **Pump-bolts**, two pieces of iron, with a knob at one end, and a hole for a pin or forelock in the other; one is to fasten the pump-spear to the brake, and the other as a screw for the brake to work upon. **Pump-fores**, long iron tubes, extending from the chain-pumps across the deck and through the side, serving to discharge the water without wetting the decks. **Pump-gear**, any materials required for fitting or repairing the pumps, as boxes, leather, &c. **Pump-spear**, that bar of iron, which, communicating with the pump box, is also attached to the end of the brake whereby the pump is put in motion. **The Pump sucks**, is said of the pump when the water is drawn out, and there comes up nothing but air and wind.

Chain Pump, consists of a long chain equipped with a sufficient number of valves at proper distances, which working upon wheels, one above and the other below, passes downward through a wooden tube, and returns upward through another, managed by a long winch or roller, whereon several men may be employed at once, and thus it discharges in a limited space a much greater quantity of water than the common pump, with less fatigue and inconvenience to the labourers.

Hand Irons of the following description have been made by engineers, and they have answered very well when properly constructed. They are described in the 62d No. of the *Mechanic's Magazine*, thus:—Fig. 1 is the plan generally adopted for a common lifting pump. A is the pump standard, with handle B connected to it; C the pump rod; D a sling, with a sliding joint at each end; the upper part of the pump rod C passes through a guide above the joint G, which always keeps the pump rod upright; the joints should be bushed with steel, steel pins turned and fitted nicely, and they will last for years without shaking in the least. But when I am confined to a room, as is frequently the case, I use fig. 3, where A is the joint of the pump lever or handle; B a radius rod of the same length from B to E, as the pump lever from A to D; the D and E are connected by a link with three holes in it; the pump rod is slung to the middle hole, and by the radius rod the pump lever being fixed in the same vertical plane, the handle describes a straight line, or very nearly so, provided the angle G does not much exceed 40 degrees. Fig. 2 is for deep wells, where the pump is obliged to be fixed in the well. The pump rod E is attached to a beam or lever C, which swings on the axis D; the connecting rod B is also jointed to the beam C at its extremity, the other end being fixed to the crank pin in

the flange A, which has holes, marked to F F F, at different distances from the centre, in order that the quantity of water to be raised may be regulated by giving the pump rod B a longer or shorter stroke. The flange A is firmly fixed on a shaft with a fly-wheel at the other end, and a handle fixed to turn with the weight marked W at the outer end of the beam; C has a set screw at the top side, to allow it to be removed further off,

or brought nearer to, the centre, as may be required. It should be placed so as to balance the weight of the pump rod, and half the column of water to be lifted. The inventor of this, fixed one pump, by which with the assistance of a wheel and pinion, one man with ease raised 7 gallons of water per minute from the depth of 120 feet.

Improvement in Pump Irons.—An improvement in the construction of pump irons, was invented by Mr. J Bennett, of Lincoln, about twelve months ago, and was so much approved as

to be immediately adopted by the other plumbers in that city and its neighbourhood; and as it may be beneficial to others, we allow it a place in our Dictionary.

Description.—A A represent the front edges of the pump sides or standards; B, a cast iron friction wheel, 5½ inches diameter, for the purpose of keeping the bucket-rod C in a perpendicular direction; it works in two grooves made for that purpose, in two pieces of hard wood D D, which are fastened to the sides of the standards; (fig. 2 represents a section of those pieces); E the handle, which may either be of wood or iron; F connects the handle to the centre of

the wheel by two steel bolts; G, a cast iron chair, in which is fastened a brass bush; two of these chairs are let into the side of the working standard, one on each side of the handle, and made fast by screw bolts and nuts. The handle has a fast axle, which works in the brass bushes, and which should be turned, and made to fit very exact, as should also the steel bolts. The motion will then be very steady, and the pump will last for years without getting out of repair.

consequence, when the gas in the chamber is compressed equal to 32 atmospheres, it will then raise the valve, and make it escape into the receiver, so long as the pressure does not exceed 32 atmospheres.

Before quitting the article pump, we will describe the *Centrifugal Check Hooks*, invented by Mr. E. Spear, which formed part of an apparatus for the prevention of accidents in raising men or minerals out of mines, by means of a rope and bucket. The idea of centrifugal check-hooks appearing to be new, and

applicable in other machines, for the purpose of stopping them when put into inordinate motion, or *running wild*, as the phrase is, the Society of Arts, &c. rewarded the inventor with their silver Vulcan medal, and directed that it should be inserted in their Transactions.

Fig. 1 is a front view, and fig. 2 is a side view, of the apparatus; *aa*, a bar fixed on the end of the axis *d*, fig. 2; *bb*, two hooks swinging freely on the ends of the same bar; *c*, a short bar projecting from the frame of the machine for the hooks to catch hold of. When the bar *aa* revolves moderately, the hooks *bb* hang down by their own gravity, and keep clear of the bar *c*, but when it revolves too quick, the centrifugal force causes them to diverge, as shewn by the dotted lines, and one of them catches hold of the check bar *c*, and stops the revolution of the axis entirely.

PUNCHEON, a little block or piece of steel, on one end whereof is some figure, letter, or mark engraved either in creux or relief, impressions of which are taken on metal or some other matter by striking it with a hammer on the end not engraved. There are various kinds of these puncheons used in the mechanical arts; such for instance are those of goldsmiths, cutlers, pewterers, &c.

PUNCTUATION, the art of dividing a written composition into sentences, or parts of sentences, by points or stops, for the purpose of marking the different pauses which the sense requires.

PUNICA, the *Pomegranate Tree*, a genus of the monogynia order, in the icosandria class of plants, and in the natural method ranking under the 39th order pomaceæ. The calyx is quinquefid, superior; there are five petals; the fruit is a multi-locular and polyspermous apple.—The fruit of the pomegranate is about the size of an orange, and has the general qualities of the other sweet summer fruits, allaying heat, quenching thirst, and gently loosening the belly. The rind is a strong astringent, and as such is occasionally made use of.

PUNT, a sort of flat-bottomed boat, whose floor resembles the platform of a floating stage. They are used in caulking, breasting, or repairing the bottom of a ship, and in shallow rivers.

PURCHASE, in Law, the buying or acquiring of lauds, &c. with money, by deed or agreement, and not by descent or right of inheritance. A joint purchase is when two or more persons join together in the purchase.

PURCHASE, a name given to any sort of mechanical power employed in raising or removing heavy bodies, or in fixing or extending the ship's rigging; such are the tackles, windlasses, winches, capstans, screws, and handspikes.

PURITAN, a name formerly given in derision to the dissenters from the church of England, on account of their professing to follow the pure word of God in opposition to all traditions and pure constitutions.

PURLINS, in Building, those pieces of timber that lie across the rafters on the inside, to keep them from sinking in the middle of their length.

PURPLE, a colour composed of a mixture of red and blue.

PURSER, an officer appointed by the lords of the admiralty to take charge of the provisions of a ship of war, and to

see that they are carefully distributed to the officers and crew, according to the general printed naval instructions.

PURSUIT, CURVE OF, is one generated by the motion of a point, which is always directed towards another point also in motion along a right line, the velocity of the two points bearing any determinate ratio to each other. Thus let *A* and *B* be two bodies, the one *A* moving along the line *AC*, with any given velocity *v*; and the other *B*, moving with a velocity *V*, and in such a manner as to be always directed towards the body *A*, then is the curve *BC*

thus described by *B*, the curve of chase or the curve of pursuit. **PUS**. The liquid called pus is secreted from the surface of an inflamed part, and usually moderates and terminates the inflammation.

PUTLOGS, or **PUTLOCKS**, in Building, are short pieces of timber about seven feet long, used in building scaffolds. They lie at right angles to the wall, with one of their ends resting upon it, and the other upon the poles which lie parallel to the side of the wall of the building.

PUTREFACTION. The decomposition of animal and vegetable matter, accompanied with a foetid smell. The solid and fluid parts are changed in gaseous matter and vapours, and earthy particles remain. If animal or vegetable substances be congealed by hard frost, or made very dry and hard, so that no motion of their particles can take place, putrefaction is stopped.

PUTTY, in the Arts. When tin is melted in an open vessel, its surface soon becomes covered with a gray powder, which is an oxide of the metal. If the heat is continued, the colour of the powder gradually changes, and at last becomes yellow. In this state it is known by the name of putty, and employed in polishing glass and other hard substances.

PUTTY, is also a kind of paste compounded of whiting and linseed oil, beaten together to the consistence of a thick dough.

PUY DE DOMME, EXPERIMENT OF, a term under which the celebrated experiment of Pascal is commonly spoken of, and by which the gravity of the atmosphere was demonstrated beyond every possible objection. It was some time after Torricelli had first asserted the pressure of the atmosphere, before philosophers could divest themselves of their prejudices on this head; and various hypotheses were accordingly advanced to account for the suspension of the mercury in the tube, as stated in the Torricellian experiment. Even Pascal had his doubts on the subject. At length, however, he suggested that if the pressure of the atmosphere was the real cause of that suspension, the mercury ought to sink very sensibly on ascending a high mountain, and the Puy de Domme was selected for this purpose. On making the experiment, the result realized his expectation; the mercury having gradually sunk in the ascent where it was extremely obvious; and rose again, upon descending, to the same height as at first. No doubt could then any longer remain as to the real cause of the suspension, and it was accordingly universally admitted by every philosopher in Europe, and the name of the mountain was from that time transferred to the experiment, which is now usually called the Experiment of the Puy de Domme.

PUZZOLANA, or **POZZULANA**, a kind of earth found about Puteoli, Baia, and Cumæ, in the kingdom of Naples. It is thrown out from the burning mouths of volcanoes, in the form of ashes; sometimes in such large quantities, and with so great violence, that whole provinces have been covered with it to a considerable distance. Puzzolana is of a gray, brown, or blackish colour; of a loose, granular, or dusty and rough, porous or spongy texture, resembling a clay hardened by fire, and then reduced to a gross powder. It has various heterogeneous substances mixed with it. Its specific gravity is from 2.5 to 2.8; and it is, in some degree, magnetic; it scarcely effervesces with acids, though partially soluble in them. It easily melts per se; but its most distinguishing property is, that it hardens very suddenly when mixed with one-third of its weight of lime and water, and forms a cement which is more durable in water than

any other. According to Bergman's analysis, 100 parts of it contain from 55 to 60 of siliceous earth, 20 of argillaceous, 5 to 6 of calcareous, and from 15 to 50 of iron. Its effects, however, in cement may, perhaps, depend only upon the iron, which has been reduced into a particular substance by means of subterraneous fires; evident signs of which are observable in the places where it is obtained.

PYRAMID, in Geometry, is a solid having any plane figure for its base, and triangles for its sides, all terminating in one common point or vertex. If the base of the pyramid is a regular figure, the solid is called a regular pyramid, which then takes particular names according to the number of its sides, as triangular, square, pentagonal, &c. the same as the prism. See PRISM. If the perpendicular demitted from its vertex falls on the centre of the base, the solid is called a *right* pyramid, but if not it is *oblique*. The principal properties of the pyramid may be stated as follows:—1. Every pyramid is one-third of a prism of equal base and altitude. 2. Pyramids of equal bases and altitudes are equal to each other, whether the figure of their bases be similar or dissimilar. 3. Any section of a pyramid parallel to its base will be similar to the base, and these areas will be to each other as the squares of their distances from the vertex. 4. Pyramids, when their bases are equal, are to each other as their altitudes, and when their altitudes are equal they are to each other as their bases; and when neither are equal, they are to each other in the compound ratio of their bases and altitudes.

To find the Solidity of a Pyramid.—Multiply the area of the base by its perpendicular altitude, and one-third of the product will be the solidity.

To find the Surface of a Pyramid.—Multiply the perimeter of the base by the slant altitude of one of its faces, and half the product will be the surface. Or, find the area of one of its triangular faces, and multiply by the number of them, which is the same thing.

Frustrum of a Pyramid.—Is the solid formed by cutting off the upper part of a pyramid by a section parallel to its base.

To find the Solidity and Surface of a Frustrum of a Pyramid.—Let A represent the area of the greater end, a that of the less, and h its height or altitude; also let S and s represent the corresponding sides of the two ends, and p the tabular number, answering to the particular figure of the base; then,

$$1. \text{Solidity} = (A + \sqrt{Aa} + a) \times \frac{1}{3}h$$

$$2. \text{Solidity} = (S^2 + Ss + s^2) \times \frac{1}{3}p$$

$$3. \text{Surface} = (S + s) \times nb$$

where n is the number of sides, and b the slant height of the frustrum.

The pyramids of Egypt have been considered from time immemorial, among the most stupenduous wonders of the world; and no one can doubt that in strength and elevation they are superior to any other monuments that art can boast. Of these venerable buildings the most remarkable are the three pyramids of Memphis. The dimensions of the largest of them have been variously estimated. According to Greaves, its perpendicular elevation is 490 feet, and its oblique height 625 feet, which latter is the measure of its base. Its four faces look towards the four cardinal points of the compass: each face has a base of 110 fathoms, and each face forms an equilateral triangle. It results from these dimensions, and from the latitude under which this pyramid is raised, that, fourteen days before the spring equinox, (the precise epoch in which the Persians celebrated the renewing of nature,) it would cease to throw any shadow at mid-day, and that it would not project any shadow again (at mid-day) until fourteen days after the autumnal equinox; consequently, the day on which the sun's southern declination was 5 deg. 15 min. (which happened twice a year—once before the vernal equinox, and once after the autumnal equinox,) the sun would appear at mid-day precisely upon the very pinnacle of the pyramid. His majestic disk, placed upon that immense pedestal, would seem to repose upon it for some minutes, whilst his adorers, kneeling down at its foot, prolonging their view along the inclined plane of the northern face of the pyramid, contemplated the great Osiris, either as he descended into the shade of the tomb, or as he rose triumphant out of it. It would appear that the Egyptians, ever great in all their designs, had executed a project, the most daring which

imagination could conceive, that of placing a pedestal for the sun and for the moon, or for Osiris and Isis, at mid-day for the one, and at midnight for the other, when they arrived in that part of the heavens near which the line passes that separates the northern from the southern hemisphere, the reign of good from the reign of evil, the empire of light from the empire of darkness.—This pyramid covers upwards of eleven English acres, and may be ascended on the outside by about 208 steps. The symmetry of the work is equal to its durability, and in all probability these renowned fabrics will continue till the globe itself shall be dissolved.

PYRITES, a genus of inflammable substances, composed of sulphur which has dissolved or saturated itself with metals.

PYRITES, a native compound of metal, with sulphur.

PYROLIGNEOUS ACID. Pyroligneous acid, or what is generally termed vinegar of wood, is that which promises to be of most use as an animal antiseptic. From its low price it is adapted for general use; more particularly, as it not only preserves the food from putrefaction, but also gives it that smoky and acid taste peculiar to well-dried hams and red herrings. Indeed the only difference in using this acid, and drying by turf or wood smoke, seems to be merely the mode of operation; for in both cases this acid is the agent employed. In one case, the animal substance is acted on during the distillation of the acid; and in the other, the already-formed acid is applied to the substance by immersion.—This acid, the product of the distillation of wood, is now well known in Britain as an article of commerce, and in its native state is a liquid of the colour of white wine, possessing a strong acid and slightly astringent taste, combined with an empyreumatic smell. When allowed to remain in a state of rest for eight or ten days, tar of a black colour subsides, and the acid is then comparatively transparent. Besides its antiseptic use, this acid is employed instead of acetate of lead by the calico printers, to make their acetate of alumina, or iron liquor. Though not very pure, it answers sufficiently well for blacks, browns, drabs, &c.; but for yellows and reds it is not so good, owing to the oil and tartar that is in combination with it.

PYROMALIC ACID, is obtained from the malic or sorbic acid, by distilling in a retort.

PYROMETER, a machine contrived to measure the expansion of metals and other bodies, occasioned by heat. Muschenbroeck was the original inventor of the pyrometer; the nature and construction of his instrument may be understood from the following account. If we suppose a small bar of metal, 12 or 15 inches in length, made fast at one of its extremities, it is obvious that if it be dilated by heat it will become lengthened, and its other extremity will be pushed forwards. If this extremity then be fixed to the end of a lever, the other end of which is furnished with a pinion adapted to a wheel, and if this wheel move a second pinion, the latter a third, and so on, it will be evident that by multiplying wheels and pinions in this manner, the last will have a very sensible motion; so that the moveable extremity of the small bar cannot pass over the hundredth or thousandth part of a line, without a point of the circumference of the last wheel passing over several inches. If this circumference then have teeth fitted into a pinion, to which an index is attached, this index will make several revolutions, when the dilatation of the bar amounts only to a quantity altogether insensible. The portions of this revolution may be measured on a dial plate, divided into equal parts; and by means of the ratios which the wheels bear to the pinions, the absolute quantity which a certain degree of heat may have expanded, the small bar can be ascertained; or, conversely, by the dilatation of the small bar, the degree of heat which has been applied to it may be determined. Such is the construction of Muschenbroeck's pyrometer. It is necessary to observe, that a small cup is adapted to the machine, in order to receive the liquid or fused matters, subjected to experiment, and in which the bar to be tried is immersed. When it is required to measure, by this instrument a considerable degree of heat, such as that of boiling oil or fused metal, fill the cup with the matter to be tried, and immerse the bar of iron into it. The dilatation of the bar, indicated by the index, will point out the degree of heat it has assumed, and which must necessarily be equal to that of the matter into which it is immersed. This machine evidently serves

to determine the ratio of the dilatation of metals, &c.; for by substituting in the room of the pyrometric bar other metallic bars of the same length, and then exposing them to an equal degree of heat, the ratios of their dilatation will be shown by the motion of the index.

Muschenbroeck has given a table of the expansion of the different metals in the same degree of heat. Having prepared cylindrical rods of iron, steel, copper, brass, tin, and lead, he exposed them first to a pyrometer with one flame in the middle; then with two flames; and successively to one with three, four, and five flames. But previous to this trial, he took care to cool them equally, by exposing them some time upon the same stone, when it began to freeze, and Fahrenheit's thermometer was at thirty-two degrees. The effects of these experiments are digested in the following table where the degrees of expansion are marked in parts equal to the $\frac{1}{1750}$ part of an inch.

It is to be observed of tin, that it will easily melt, when heated by two flames placed together. Lead commonly melts with three flames, placed together, especially if they burn long. From these experiments, so far as they are correct, it appears, at first view, that iron is the least rarefied of any of these metals, whether it be heated by one or more flames; and therefore is most proper for making machines or instruments which we would have free from any alterations by heat or cold, as the rods of pendulums for clocks, &c. So likewise the measures of yards or feet should, if of metal, be made of iron, that their length may be as nearly as possible the same, summer and winter.

Expansion of	Iron.	Steel	Copper	Brass.	Tin.	Lead
By one flame,	80	85	89	110	163	155
By two flames placed close together,	117	123	115	220		274
By two flames $2\frac{1}{2}$ inches distant,	100	94	92	141	219	263
By three flames placed close together,	142	168	193	275		
By four flames placed close together,	211	270	270	361		
By five flames,	290	310	311	377		

By the help of this instrument Mr. Ellicot found upon a pendulum, that the expansion of bars of different metals, as nearly of the same dimensions as possible, by the same degree of heat, were as follow.

Gold.	Silver.	Brass.	Copper.	Iron.	Steel.	Lead.
73	103	95	89	60	56	149

The great difference between the expansions of iron and brass has been applied with good success to remedy the irregularities in pendulums arising from heat. (Phil. Trans. vol. xvii. p. 485.)

Mr. Graham used to measure the minute alterations, in length of metal bars, by advancing the point of a micrometer-screw, till it sensibly stopped against the end of the bar to be measured. This screw, being small and very lightly hung, was capable of agreement within the three or four thousandth part of an inch. On this general principle Smeaton contrived his pyrometer, in which the measures are determined by the contact of a piece of metal with the point of a micrometer screw.

The late Mr. Ferguson also invented two pyrometers, descriptions and figures of which are given in his Lectures.

Mr. Wedgwood, the ingenious manufacturer of the finest earthenware from basaltic masses, or *terra cotta*, has contrived a curious pyrometer: he employs small cubes of dry clay: because that species of earth has the remarkable property of contracting in its bulk, when submitted to the fire, and not again expanding on suddenly exposing it to the cold air. In order to ascertain the precise degree of heat in an oven, he puts one of

his clay cubes into it, and after having acquired the temperature of the place, he immediately plunges it into cold water. Now, the size of the cube (that was exactly adjusted to half an inch square) is measured between two brass rules, the sides of which are somewhat obliquely disposed, so as to form an inclining groove, into which the cube may be slid. In proportion as the bulk of the latter has been contracted by heat, it passes down deeper between the scales, on which the various degrees of temperature have been previously marked. Thus, when the division of the scale commences from the point of red heat visible in day-light, and the whole range is divided into 240 equal parts, it will be found that Swedish copper melts at 26; gold at 32; iron at from 130 to 150 degrees; above this point, the cubes could not be heated. But if one of these clay squares be put into an oven where other materials, such as bread, earthenware, &c. are to be baked, they may be usefully employed for regulating the necessary degree of heat. Perhaps, however, this gauge does not afford so constant and accurate a measure for the highest degrees of heat, as the dilation of mercury or of alcohol does for the lower.

PYROPHORUS. By this name is denoted an artificial product, which takes fire or becomes ignited on exposure to the air. Hence, in the German language, it has obtained the name of *left-zunder*, or air tinder. It is prepared from alum by calcination, with the addition of various inflammable substances.

PYROTECHNY, is, properly speaking, the science which teaches the management and application of fire in divers operations; but in a more limited sense, and as it is more commonly used, it refers chiefly to the composition, structure, and use of artificial fire-works. The ingredients are, 1. saltpetre, purified for the purpose; 2. sulphur, and 3. charcoal. Gunpowder is likewise used in the composition of fire-works, being first ground, or, as it is technically termed, mealed. Camphor and gum benzoin are employed as ingredients in odoriferous fire-works. The proportions of the materials differ very much in different fire-works, and the utmost care and precaution are necessary in the working them to a state fit for use, and then in the mixing. In this work we cannot enter on the subject with a sufficient degree of minuteness to teach the method of making of fire-works, and shall therefore content ourselves with the brief notice of the proportions of the materials in some of the more common and more interesting articles in use. The charges for sky-rockets are made of saltpetre, four pounds; brimstone, one pound; and charcoal one pound and a half; or by another direction, saltpetre, four pounds; brimstone one pound and a half; charcoal, twelve ounces; and meal powder, two ounces. These proportions vary again according to the size of the rocket: in rockets of four ounces, mealed-powder, saltpetre, and charcoal, are used in the proportions of 10, 2, and 1; but in very large rockets the proportions are saltpetre, four; mealed powder and sulphur one each. When stars are wanted, camphor, alcohol, antimony, and other ingredients, are required according as the stars are to be blue, white, &c. In some cases gold and silver rain is required; then brass-dust, steel-dust, saw-dust, &c. enter into the composition; hence the varieties may be almost indefinite. With respect to colour, sulphur gives a blue, camphor a white or pale colour, saltpetre a clear white yellow, sal-ammoniac a green, antimony a reddish, rosin a copper colour.

PYRUS, the *Pear Tree*, a genus of the pentagynia order, is in the icosandria class of plants, and in the natural method ranking under the 36th order, pomaceae. To this genus *Linnæus* has joined the apple and quince. There are thirteen species.

PYRUS Cydonia. (*The Quince.*) The seeds abound with a mucilaginous substance, of no particular taste, which they readily impart to watery liquors: an ounce boiled in three pints of water, will render it thick and ropy, like the white of an egg. A syrup and jelly of the fruit, and mucilage of the seeds, used to be kept in the shops.

PYXIS NAUTICA, the *Sea Compass*, is of course, from its name, a modern constellation, since the instrument from which this asterism derives its title was unknown till the fourteenth century of our era. It is composed of a few stars, none of which exceed the fifth magnitude. Its place in the rigging of the constellation *Argo* renders its limits a matter of easy discrimination.

Q.

Q, or **q**, the sixteenth letter of our alphabet. As a numeral it stands for 60; and with a dash over it, thus, \overline{Q} for 600,000. Used as an abbreviation, **q** signifies quantity, or quantum; thus, among physicians, **q. pl.** is quantum placet, i. e. as much as you please of a thing; and **q. s.** quantum sufficit, i. e. as much as is necessary. **Q. E. D.** among Mathematicians, is *quod erat demonstrandum*, i. e. which was to be demonstrated; and **Q. E. F.** *quod erat faciendum*, i. e. which was to be done. **Q. D.** among Grammarians, is *quasi dictum*, i. e. as if it was said, or as who should say. In the notes of the ancients, **Q** stands for *Quintus*, or *Quintus*; **Q. B. V.** for *quod bene vertat*; **Q. S. S. S.** for *quæ supra scripta sunt*; **Q. M.** for *Quintus Mutius*, or *quomodo*; **Quint.** for *Quintilius*; and **Quas.** for *Quæster*.

QUACK, a person pretending to practise medicine, without having been regularly or properly taught. In its more enlarged sense, this term includes all empirics, particularly those in divinity and law; but it is more generally restricted to those who, without an adequate degree of learning and knowledge, make pretensions to the healing art.

QUACKILTTO, in Ornithology, the name of a beautiful Brazilian bird of the moor-hen kind. Its colour is of a fine blackish purple, variegated with white; and it imitates the crowing of the common cock.

QUADRANGLE, in Geometry, the same with a quadrilateral figure, or one consisting of four sides and four angles.

QUADRANS, the quarter or fourth part of any thing, particularly the Roman *as*, or pound.

QUADRANT, in Geometry, is either the quarter or fourth part of a circle, or the fourth part of its circumference; the arch of which, therefore, contains 90 degrees.

QUADRANT, also denotes a mathematical instrument, of great use in astronomy and navigation, for taking the altitudes of the sun and stars, as also taking angles in surveying heights and distances. There are several kinds of quadrants, which are commonly distinguished from each other, either by the names of their authors, or the purposes they are intended to answer. Thus we have *Adams's*, *Cole's*, *Davis's*, *Gunter's*, *Hadley's*, &c. **QUADRANTS**; as also the *Astronomical*, *Surveying*, &c. **QUADRANTS**. The principle upon which the construction and use of

this instrument depends, may be illustrated by the annexed figure; **ABC** is a quarter circle of brass wood, or such like, having the arc **AB** divided into degrees and minutes, from **A** to **B**; on one side **BC** are fixed two sights *a*, *b*, and at **C** is fixed a plumb-line **CP**. Now to use the instrument, hold it so that the side of the quadrant **BC** is in a line with the object **S**, whose elevation is required, or so that it may be seen through the two small sights *a*, *b*; then the degrees, &c. cut off by the plumb-line **CP**, measured from **A** towards **B**, will be the measure of the angle of elevation **DBS**, required for **DBC**, being a right-angled triangle, the two angles **DBC** and **BCD**, are together equal to a right angle, as are also the two **BCD** and **DCA**; from each of these therefore, taking away the common angle **BCD**, and there remains the angle **DCA** equal to the angle **DBA**. This is the most simple form of the quadrant, under which it is necessarily subject to very considerable inaccuracies, to remedy which a variety of forms have been given to it by different authors; but that of *Hadley's* is so decidedly superior to any other of a portable kind, that we shall limit our remarks principally to the description and use of this instrument; and a slight account of the astronomical and Gunter quadrants.

Before we attempt to describe the exact construction of this instrument, it may be of some use to the reader to illustrate the principles on which it rests, by a less complex figure than that of

the quadrant itself. Though this instrument is usually called a quadrant, it is, in fact, but an octant, or 8th part of a circle, as **QBR**, having a label or index **BM** moveable about **B** as a centre, and on this index, and in the same direction, is fixed a plane reflecting mirror, and on the side **BR** is placed another parallel to the other side **BQ**, but this is silvered only half way up, so that an object **O** may be seen directly through the plain part of the glass, from **E**, the sight vane. Now, an observer wishing, for example, to measure the angle subtended at **H** by the two objects **OS**, looks through the sight vane at **E**, and moves the index **BM**

about its centre, till the reflected image of **S** is seen in the other reflector **D**, previously in conjunction with the object **O**, as seen through the plain glass; then the angle **QBM**, or the arc **QM** = $\frac{1}{2}$ \angle **SHO**, as may be thus demonstrated.

Since the angle of incidence is equal to the angle of reflection, \angle **ABS** = \angle **DBG** = \angle **HBO**; therefore **BG** bisects the angle **HBD**. Again, for the same reason, \angle **CDB** = \angle **HDB** = \angle **ODC**; therefore **DC** bisects the angle **ODB**. Now, \angle **ODB** = \angle **DBH** + \angle **BHD**, being the external angle of the triangle **DBH**, therefore \angle **CDB** = $\frac{1}{2}$ \angle **DBH** + $\frac{1}{2}$ \angle **DHB** = \angle **DBG** + $\frac{1}{2}$ \angle **DHB**; but \angle **CDB** = \angle **DBG** + \angle **DGB**, therefore \angle **DGB** = $\frac{1}{2}$ \angle **DHB**, or since **CG** and **BQ** are parallel, and \angle **DGB** = \angle **QBG**, the angle **QBG**, or **QBM**, is also equal to half **DHB**, or half **OSH**, which was to be shewn.

This is the principle on which the construction and use of this instrument depends; but its great and extensive utility in astronomical and nautical observations, renders it necessary now to enter into a more minute description. It may be observed, that in consequence of the points **H** and **E** not coinciding, there is a small error **EH** between the true and apparent angular point, which is called the *parallax of the instrument*; this, however, is zero, in celestial observations.

The *Astronomical* **QUADRANT**, is a large one, usually made of brass or iron bars; having its limb **EF**, fig. 1, (*Plate Quadrants*), nicely divided, either diagonally or otherwise, into degrees, minutes, and seconds, if room will permit, and furnished either with two pair of plain sights or two telescopes, one on the side of the quadrant at **A**, **B**, and the other **CD** moveable about the centre by means of the screw **G**. The dented wheels **I** and **H** serve to direct the instrument to any object or phenomenon. The application of this useful instrument, in taking observations of the sun, planets, and fixed stars, is obvious: for being turned horizontally upon its axis, by means of the telescope **AB**, till the object is seen through the moveable telescope, then the degrees, &c. cut by the index, give the altitude, &c. required.

Description of Hadley's **QUADRANT**.—This instrument consists of the following particulars; see plate, fig. 2. 1. An octant, or the eighth part of a circle, **ABC**. 2. An index **D**. 3. The speculum **F**. 4. Two horizontal glasses, **F**, **G**. 5. Two screens, **K** and **K**. 6. Two sight vanes, **H** and **I**.

The octant consists of two radii **AB**, **AC**, strengthened by the braces **L**, **M**, and the arch **BC**; which, though containing only 45°, is nevertheless divided into 90 primary divisions, each of which stands for degrees, and are numbered 0, 10, 20, 30, &c. to 90; beginning at each end of the arch, for the convenience of numbering both ways, either for altitudes or zenith distances; also each degree is subdivided into minutes, by means of a vernier. But the number of these divisions varies with the size of the instrument.

The index **D** is a flat bar, moveable about the centre of the

instrument; and that part of it which slides over the graduated arch BC, is open in the middle, with a vernier scale on the lower part of it, under which is a screw serving to fasten it perpendicular to the plane of the instrument, the middle part of the former coinciding with the centre of the latter; and because the speculum is fixed to the index, the position of it will be altered by moving the index along the arch. The rays of an observed object are received on the speculum, and from thence reflected on one of the horizon glasses F or G; which are two small pieces of looking glass placed on one of the limbs, their faces being turned obliquely to the speculum, from which they receive the reflected rays of objects. This glass F has only its lower part silvered, and set in brass-work, the upper part being left transparent, to view the horizon. The glass G has, in its middle, a transparent slit, through which the horizon is to be seen. And, because the warping of the materials, and other accidents, may distend them from their true situation, there are three screws passing through their feet, by which they may be easily replaced.

The screens are two pieces of coloured glass, set in two square brass frames, K and K, which serve as screens to take off the glare of the sun's rays, which would otherwise be too strong for the eye: the one is tinged much deeper than the other; and as they both move on the same centre, they may be both or either of them used: in the situation they appear in the figure, they serve for the horizontal glass F; but when they are wanted for the horizon glass G, they must be taken from their present situation, and placed on the quadrant above G.

The sight-vanes are two pins H and I, standing perpendicular to the plane of the instrument: that at H has one hole in it, opposite to the transparent slit in the horizon glass G; the other, at I, has two holes in it, the one opposite to the middle of the transparent part of the horizon glass F, and the other rather lower than the quicksilvered part: this vane has a piece of brass on the back of it, which moves round a centre, and serves to cover either of the holes.

To rectify Hadley's Quadrant. For the Fore Observation.—Bring the index close to the bottom, so that the middle of the vernier's scale, or nonius, stand against 0 degrees. Hold the plane of the instrument vertical with the arch downwards; look through the right-hand hole in the vane, and direct the sight through the transparent part of the horizon glass, to observe the horizon. If the horizon, seen both at the quicksilvered part, and through the transparent part, should coincide, or make one straight line, then is the glass adjusted; but if one of the horizon lines should stand above the other, slacken the screw in the middle of the lever backwards or forwards, as there may be occasion, until the lines coincide; fasten the screw in the middle of the lever, and all is ready for use.

To take the Sun's Altitude.—Fix the screens above the horizon glass, using either or both of them, according to the strength of the sun's rays, by turning one or both the frames of those glasses close against the plane or face of the instrument; then your face being turned towards the sun, hold the quadrant by the braces, or by either radius, as is found most convenient, so as to be in a vertical position, with the arch downwards. Put the eye close to the right-hand hole in the vane, look at the horizon through the transparent part of the horizon glass, at the same time sliding the index with the left hand, until the image of the sun, seen in the quicksilvered part, falls in with the edge of the horizon, taking either the upper or the under edge of the solar image. Swing your body gently from side to side; and when the edge of the sun is observed not to cut, but to touch the horizon line, like a tangent, the observation is made. Then will the degrees on the arch, reckoning from the end next your body, give the altitude of that edge of the sun which was brought to the horizon. If the lower edge was observed, then sixteen minutes, added to the said degrees, gives the altitude of the sun's centre; but if the upper edge was used, the sixteen minutes must be subtracted.

To take the Altitude of a Star.—Look directly up at the star through the vane and transparent part of the glass, the index being close to the button; then will the image of the star, by reflection, be seen in the silvered part, right against the star seen through the other part. Move the index forward, and as the image descends, let the quadrant descend also, to keep it

in the silvered part, till it comes down in a line with the horizon, seen through the transparent part, and the observation is made.

To rectify the Instrument for the Back Observation.—Slacken the screw in the middle of the handle, behind the glass G; turn the button *k* on one side, and bring the index as many degrees before 0 as is equal to double the dip of the horizon at your height above the water; hold the instrument vertical, with the arch downwards; look through the hole of the vane H; and if the horizon, seen through the transparent slit in the glass G, coincide with the image of the horizon seen in the silvered part of the same glass, then the glass G is in its proper position; but if not, set it by the handle, and fasten the screw as before.

To take the Sun's Altitude by the Back Observation.—Put the stem of the screens K and K into the hole *r*, and in proportion to the strength or faintness of the sun's rays, let either one, or both, or neither of the frames of those glasses, be turned close to the face of the limb; hold the instrument in a vertical position with the arch downward, by the braces L and M, with the left hand; turn your back to the sun, and put one eye close to the hole in the vane H, observing the horizon through the transparent slit in the horizon glass G; with the right hand move the index D, till the reflected image of the sun be seen in the silvered part of the glass G, and in a right line with the horizon; swing your body to and fro, and if the observation be well made the sun's image will be observed to brush the horizon, and the degrees reckoned from C, or that part of the arch farthest from your body, will give the sun's altitude, at the time of observation; observing to add 16 for the sun's semidiameter, if the sun's upper edge be used, and subtract the same for the lower edge.

The directions just given, for taking the altitudes at sea, would be sufficient, but for two corrections that are necessary to be made before the altitude can be accurately determined, viz. one on account of the observer's eye being raised above the level of the sea, and the other on account of the refraction of the atmosphere, especially in small altitudes. The following tables therefore shew the corrections to be made on both these accounts; the first referring to the dip of the horizon; and the other to the refraction in altitude; the method of using which is given, in the following column.

TABLE I.—Dip of the Horizon.

Height of the Eye in Feet.	DIP.	Height of the Eye in Feet.	DIP.	Height of the Eye in Feet.	DIP.
1	0' 57"	12	3' 18"	35	5' 30"
2	1 21	14	3 24	40	6 2
3	1 39	16	3 47	45	6 24
4	1 55	18	4 3	50	6 44
5	2 8	20	4 10	60	7 23
6	2 20	22	4 28	70	7 29
7	2 31	24	4 40	80	8 32
8	2 42	26	4 52	90	9 3
9	2 52	28	5 3	100	9 33
10	3 1	30	5 14		

TABLE II.—Refraction in Altitude.

Apparent Altitude in Degrees.	Refraction.	Apparent Altitude in Degrees.	Refraction.	Apparent Altitude in Degrees.	Refraction.
0	33' 0"	8	6' 29"	40	1' 8"
$\frac{1}{2}$	30 35	9	5 48	45	0 57
$\frac{1}{4}$	28 22	10	5 15	50	0 48
$\frac{1}{8}$	24 29	11	4 47	55	0 40
$\frac{1}{16}$	18 35	12	4 23	60	0 33
$\frac{1}{32}$	14 36	15	3 30	65	0 26
$\frac{1}{64}$	11 51	20	2 35	70	0 21
$\frac{1}{128}$	9 54	25	2 2	75	0 15
$\frac{1}{256}$	8 29	30	1 38	80	0 10
$\frac{1}{512}$	7 20	35	1 21	85	0 5

General Rules for the Corrections.—1. In the fore observations, add the sum of both corrections to the observed zenith distance, to get the true zenith distance; or subtract the said sum from the observed altitude for the true one. 2. In the back observation, add the dip and subtract the refraction for altitudes; and for zenith distances, do the contrary, viz. subtract the dip and add a refraction.

Exam. By a back observation the altitude of the sun's lower limb was found by Hadley's quadrant to be $25^{\circ} 12'$; the eye being 30 feet above the horizon. By the tables the dip on 30 ft is $5' 14''$, and the refraction on $25^{\circ} 12'$ is $2' 1''$. Hence

Apparent alt. lower limb..... $25^{\circ} 12' 0''$
Sun's semidiameter, sub..... $0 16 0$

Appar. alt. of centre..... $24 56 0$
Dip of horizon, add..... $0 5 14$

$25 1 14$

Refraction subtract..... $0 2 1$

True alt. of centre..... $24 59 13$

In the case of the moon, besides the two corrections above another is to be made for her parallax. But for all these particulars, see the requisite tables for the Nautical Almanac, &c.

QUADRANT, the Common or Surveying. This instrument, ABC fig. 3, is made of brass, or wood, &c.; the limb or arch of which is divided into 90 deg. and each of these is farther divided into as many equal parts as the space will allow, diagonally or otherwise. To one of the radii AC are fitted two moveable sights; and to the centre is sometimes also annexed a label, or moveable index AD, bearing two other sights; but instead of these last sights there is sometimes fitted a telescope. Also from the centre hangs a thread with a plummet; and on the under side or face of the instrument are fitted a ball and socket, by means of which it may be put into any position. The general use of it is for taking angles in a vertical plane, comprehended under right lines going from the centre of the instrument one of which is horizontal, and the other is directed to some visible point. But besides the part above described, there is often added, on the face, near the centre, a kind of compartment EF, called a quadrant or geometrical square, which is a kind of separate instrument, and is particularly useful in altimetry and longimetry, and measuring heights and distances.

QUADRANT, Cole's, is a very useful instrument, invented by Mr. Benjamin Cole. It consists of six parts, viz. the staff AB, fig. 4; the quadrantal arch DE; three vanes A, B, C; and their vernier FG. The staff is a bar of wood about two feet long, an inch and a quarter broad, and of a sufficient thickness to prevent it from bending or warping. The quadrantal arch is made of wood, and is divided into degrees or third parts of degrees, to a radius of about nine inches; and to its extremities are fitted two radii, which meet in the centre of the quadrant by a pin, about which it easily moves. The sight-vane A is a thin piece of brass, near two inches in height and one broad, set perpendicularly on the end of the staff, A, by means of two screws passing through its foot. In the middle of this vane is drilled a small hole, through which the coincidence or meeting of the horizon and solar spot is to be viewed. The horizontal vane B is about an inch broad and two inches and a half high, having a slit cut through it of near an inch long and a quarter of an inch broad; this vane is fixed in the centre-pin of the instrument, in a perpendicular position by means of two screws passing through its foot, by which its position with respect to the sight-vane is always the same, their angle of inclination being equal to 45 degrees. The shade-vane C is composed of two brass plates. The one which serves as an arm is about $4\frac{1}{2}$ inches long and $\frac{1}{4}$ of an inch broad, being pinned at one end to the upper limb of the quadrant by a screw, about which it has a small motion; the other end lies in the arch, and the lower edge of the arm is directed to the middle of the centre pin. The other plate, which is properly the vane, is about two inches long, being fixed perpendicularly to the other plate at about half an inch distance from that end next the arch; this vane may be used either by its shade, or by the solar spot cast by a convex lens placed in it. And because the

wood work is often subject to warp or twist, therefore this vane may be rectified by means of a screw, so that the warping of the instrument may occasion no error in the observation, which is performed in the following manner: set the line G on the vernier against a degree of the upper limb of the quadrant; and turn the screw on the back side of the limb, forward or backward, till the hole in the sight-vane, the centre of the glass and the sunk spot in the horizon-vane, lie in a right line.

QUADRANT, Collins's or Sutton's, fig. 5, is a stereographic projection of one quarter of the sphere between the tropics, upon the plane of the ecliptic, the eye being in its north pole; and fitted to the latitude of London. The lines running from right to left, are parallels of latitude; and those crossing them are azimuths. The smaller of the two circles bounding the projection is one quarter of the tropic of Capricorn; and the greater is a quarter of the tropic of Cancer. The two ecliptics are drawn from a point on the left edge of the quadrant, with the characters of the signs upon them; and the two horizons are drawn from the same point. The limb is divided both into degrees and time; and by having the sun's altitude, the hour of the day may here be found to a minute. The quadrantal arches next the centre contain the calendar of months; and under them, in another arch, is the sun's declination. On the projection are placed several of the most remarkable fixed stars between the tropics, and the next below the projection are the quadrant and line of shadows.

QUADRANT, Gunner's, fig. 6, sometimes called gunner's square, is used for elevating and pointing cannon, mortars, &c. and consists of two branches either of wood or brass, between which is a quadrantal arch divided into 90 deg. and furnished with a thread and plummet.

QUADRANT, Gunter's, so called from its inventor, Edmund Gunter, (fig. 7.) besides the apparatus of other quadrants, has a stereographic projection of the sphere on the plane of the equinoctial; and also a calendar of the months, next to the divisions of the limb; by which, besides the common purposes of other quadrants, several useful questions in astronomy are easily resolved.

Sinical QUADRANT, is one of some use in navigation. It consists of several concentric quadrantal arches, divided into eight equal parts by means of radii, with parallel right lines crossing each other at right angles. Now any one of the arches, as BC, fig. 8, in the Plate, may represent a quadrant of any great circle of the sphere, but is chiefly used for the horizon or meridian. If then BC is taken for a quadrant of the horizon, either of the sides, as AB, may represent the meridian, and the other side AC will represent a parallel, or line of east and west; all the other lines parallel to AB will be also meridians; and all those parallel to AC, east and west lines, or parallels. Again, the eight species into which the arches are divided by the radii, represent the eight points of the compass in a quarter of the horizon; each containing 11 deg. 15 min. The arch BC is likewise divided into 90 deg., and each degree subdivided into 12 min., diagonalwise. To the centre is fixed a thread, which being laid over any degree of the quadrant, serves to divide the horizon. If the sinical quadrant is taken for a fourth part of the meridian, one side of it, AB, may be taken for the common radius of the meridian and equator; and then the other, AC, will be half the axis of the world. The degrees of the circumference, BC, will represent degrees of latitude; and the parallels to the side, AB, assumed from every point of latitude to the axis, AC, will be radii of the parallels of latitudes, as likewise the cosine of those latitudes. Hence, suppose it is required to find the degrees of longitude contained in 83 of the lesser leagues in the parallel of 48 deg.; lay the thread over 48 deg. of latitude on the circumference, and count thence the 83 leagues on AB, beginning at A; this will terminate in H, allowing every small interval four leagues. Then tracing out the parallel HE, from the point H to the thread, the part AE of the thread shows that 125 greater or equinoctial leagues make 6 deg. 15 min.; and therefore that the 83 lesser leagues AE, which make the difference of longitude of the course, and are equal to the radius of the parallel HE, make 6 deg. 15 min. of the said parallel. When the ship sails upon an oblique course, such course, besides the north and south greater leagues, gives lesser leagues easterly and westerly, to be re-

QUALITY, that affection of a thing whence its denomination is derived. Hence, quality is said to be an attribute from which no substance is exempt. Qualities are of various kind, physical, intellectual, moral, primary, secondary, essential, relative, active, passive, &c. The term is applicable to animate and inanimate being.

QUANTITY, in Grammar, an affection of a syllable, whereby its measure, or the time wherein it is pronounced, is ascertained; or that which determines the syllable to be long or short. Quantity is also the object of prosody, and distinguishes verse from prose; and the economy and arrangement of quantities, that is, the distribution of long and short syllables, make what we call the number. The quantities are distinguished, among grammarians, by the characters $\acute{}$, short, as *per*; and $\bar{}$, long, as *ros*. There is also a common, variable, or dubious quantity; that is, syllables that are one time taken for short ones, and at another time for long ones; as the first syllable in *atlas*, *patres*, &c. Feet are made up of quantities. The quantity of syllables is known two ways. 1. By rules for that purpose. And, 2. By authority. The rules for this end are taught by that part of grammar called prosody; the authority made use of in this case is no more than examples from, or the testimony of, approved authors; and is never used but either when the rules are deficient, or when we are unacquainted with them.

QUANTUM VALEBANT, is where goods and wares sold are delivered by a tradesman at no certain price, or to be paid for them as much as they are worth in general; and the plaintiff is to aver them to be worth so much.

QUANTUM MERUIT, in Law, is an action upon the case, founded on the necessity of paying a person for doing any thing as much as he deserves.

QUARANTINE, a trial which ships undergo when suspected of having on board persons infected with a pestilential disease. Physicians are occasionally consulted on this subject by government; who regulate this unpleasant restriction on the commerce of the country by their judgment, as to the period of time within which the effects of any infection, received by any individual on board, would be shewn. The usual quarantine is forty days. This may be ordered by the king, with the advice of the privy-council, at such times, and under such regulations, as he judges proper. Ships ordered on quarantine must repair to the place appointed, and must continue there during the time prescribed, without having any intercourse with the shore, except for necessary provisions, which are conveyed with every possible precaution. When the time is expired, and the goods opened and exposed to the air as directed, if there be no appearance of infection, they are admitted to port. Ships infected with the pestilence must proceed to St. Helen's Pool in the Scilly islands, and give notice of their situation to the custom-house officers, and wait till the king's pleasure be known. Persons giving false information, to avoid performing quarantine, or refusing to go to the place appointed, or escaping; also officers appointed to see quarantine performed, deserting their office, neglecting their duty, or giving a false certificate; suffer death as felons. Goods from Turkey or the Levant may not be landed without license from the king, or certificate that they have been landed and aired at some foreign port.

QUARE, in Law, a term affixed to the title of several writs.

QUARRY, the common name of an opening or pit dug into the earth, from which slate, marble, stones, and ores of various kinds, are to be raised, for purposes to which they are applicable.

QUARTER, in Law, the fourth part of a year; and hence the days on which these quarters commence are called *quarter-days*, viz. March 25, or Lady-day; June 24, or Midsummer-day; September 29, or Michaelmas; and December 21, or St. Thomas the Apostle's day. On these days rents on leases, &c. are usually reserved to be paid; though December 25, or Christmas-day, is commonly reckoned the last quarter-day.

QUARTER, the fourth part of any thing, the fractional expression for which is $\frac{1}{4}$. Quarter in weights, is generally used for the fourth part of a hundred weight avoirdupois, or 25 lb. Used as the name of a dry measure, quarter is the fourth part of a ton in weight, or eight bushels.

QUARTER, in Heraldry, is applied to the parts or members

of the first division of a coat that is quartered, or divided into four quarters.

QUARTER of a Point, in Navigation, is the fourth part of the distance between two cardinal points, which is 2 deg. 48. min.

QUARTER, that part of a ship's side which lies towards the stern, or which is comprehended between the aft-most end of the main chains, and the sides of the stern, whence it is terminated by the quarter-pieces. Although the lines by which the quarter and bow of a ship, with respect to her lengths, are only imaginary, yet experience appears sufficiently to have ascertained their limits; so that if we were to divide the ship's sides into five equal portions the names of each space would be readily enough expressed; thus the first from the stern would be the quarter; the second, abaft the midships; the third, the midships; the fourth, before the midships; and the fifth, the bow.

On the QUARTER, may be defined a point in the horizon, considerably abaft the beam, but not in the direction of the ship's stern. See the article **BEARING**.

QUARTER Bill, a list, containing the different stations to which the officers and crew are quartered in time of battle, with the names of the persons appointed to those stations.

QUARTER Clothes, long pieces of painted canvass, extended on the outside of the quarter-netting, from the upper part of the gallery to the gangway.

QUARTER Gallery. See **GALLERY**.

QUARTER Master, in the Navy, an inferior officer appointed to assist the mates in their several duties, as stowing the hold, soiling the cables, attending the steerage, and keeping time by the watch-glasses.

QUARTER Master's Mate, an officer under the preceding.

QUARTER-Rails, are narrow moulded planks, reaching from the top of the stern to the gangway, and serving as a fence to the quarter-deck.

QUARTERING, in Gunnery, is when a piece of ordnance is so traversed that it will shoot on the same line, or on the same point of the compass, as the ship's quarter bears.

QUARTERING, in Heraldry, in dividing a coat into four or more quarters or quarterings, by parting, coupling, &c. that is, by perpendicular and horizontal lines, &c.

QUARTERS, imply the several stations where the officers and crew of a ship of war are posted in time of action. See the articles **BATTLE**, **ENGAGEMENT**, &c. The lieutenants are generally quartered on the different decks, to command the batteries; the master superintends the management of the ship; the boatswain and a sufficient number of men, are stationed to repair the damaged rigging; the gunner, usually on the lower gun-deck, and the carpenter, with his mates and crew, in the wings on the orlop. The marines are generally quartered on the poop and fore-castle, or gangway, under the direction of their officers, although, on some occasions, they assist at the great guns, particularly in distant cannonading; and the great body of the seamen are stationed at the cannon or in the tops; while the captain is ever on the quarter-deck, giving directions to all around, and animating every one by his example.

The number of men appointed to manage the artillery is always in proportion to the nature of the guns, and the number and condition of the ship's crew. They are in general as follow, when the ship is full manned, so as to fight both sides at once occasionally: *Nature of the Guns*.—To a 42-pounder, 15 men; to a 32, 13 men; to a 24, 11 men; to a 18, 9 men; to a 12, 7 men; to a 9, 6 men; to a 6, 5 men; to a 4, 4 men; to a 3, 3 men. This number, to which is often added a boy, to bring powder to every gun, may be occasionally reduced, and the guns nevertheless well managed. The number of men appointed to the small arms:—1st rate 150 men to the small arms; 2d rate, 120 ditto; 3d rate of 80 guns, 100 ditto; 3d rate of 70 guns, 80 ditto; 4th rate of 60 guns, 70 ditto; 4th rate of 50 guns, 60 ditto; 5th rate, 50 ditto; 6th rate, 40 ditto; sloops of war, 30 ditto.

QUARTERS, is also an exclamation to implore mercy from a victorious enemy.

QUARTERS of the Yards, the space comprehended between the slings or middle, and the outer parts or the yard-arms.

QUARTER Tackle, a strong tackle fixed occasionally upon the quarter of the main-yard, to hoist heavy bodies in or out of the ship.

QUARTER-SESSIONS. The sessions of the peace is a court of record holden before two or more justices, whereof one is of the quorum, for the execution of the authority given them by the commission of the peace, and certain statutes and acts of parliament. The justices keep their sessions in every quarter of the year at least, and for three days if need be; to wit, in the first week after the feast of St. Michael, in the first week after the Epiphany, in the first week after Easter, and in the first week after St. Thomas, and oftener if need be. Any two justices, one whereof is of the quorum, by the words of the commission of the peace, may issue their precept to the sheriff, to summon a session for the general execution of their authority; and such session, holden at any time within that quarter of a year, is a general quarter-session, and the sheriff must summon a jury under their authority. There are many offences, which, by particular statutes, belong properly to this jurisdiction, and ought to be prosecuted in this court, as the smaller misdemeanors, not amounting to felony, and especially offences relating to the game laws, highways, alehouses, bastard children, the settlements and provision of the poor, vagrants, servants' wages, apprentices, and popish recusants. Some of these are proceeded upon by indictment, and others in a summary way, by motion and order, which may, for the most part, unless guarded against by any particular statute, be removed into the Court of King's Bench by certiorari, and be there either quashed or confirmed. The business done at quarter sessions has become of the highest importance to the country, and the public are greatly indebted to those magistrates who have sufficient knowledge of law to perform the duties of their office and give their attendance. In Ireland a practising barrister is appointed at each session to assist as chairman. In England this is not generally the case by law, but barristers are chiefly preferred, and the duty to be performed is so multifarious, that it requires no small skill in law, accompanied with much activity and industry, to execute it justly.

QUARTZ, a mineral of the flint genus, which is divided into five sub-species: viz. the amethyst, the rock-crystal, milk-quartz, common quartz, and prase.

QUASSIA, a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under the 14th order, grinales. The calyx is pentaphyllous; there are five petals; the nectarium is pentaphyllous; there are from two to five seed-cases, standing asunder, and monospermous. There are three species, the amara, simaruba, and excelsa. The different species are much used in medicine, and by the brewers, to give a bitter taste to their beer.

QUAY, or **KEY**, a place to land goods upon.

QUEEN, a woman who holds a crown singly. The title of queen is also given by way of courtesy to her that is married to a king, who is called by way of distinction queen-consort.

QUERCITRON, in Dying, the internal bark of the quercus nigra; it yields its colour, which is yellow, by infusion in water, and by the common mordants gives a permanent dye. See **DYEING**.

QUERCUS, in Botany, the *Oak-tree*, a genus of the monocæia polyandria class and order. The wood of the oak, when of a good sort, is well known to be hard, tough, tolerably flexible, not easily splintering, strong without being too heavy, and not easily admitting water; for these qualities it is preferred to all other timber for building ships; it would be difficult to enumerate all the uses to which it may be applied. Oak saw-dust is the principle indigenous vegetable used in dyeing fustian; all the varieties of drabs and different shades of brown are made with oak saw-dust, variously managed and compounded. Oak apples are also used in dying, as a substitute for galls. See **CORK**.

QUICK, or **QUICKSET HEDGE**, among Gardeners, denotes all live hedges, of whatsoever sort of plants they are composed, to distinguish them from dead hedges; but in a more strict sense of the word, it is restrained to those planted with the hawthorn, or *cratægus oxyacantha*, under which name these young plants, or sets, are sold by the nursery-gardeners, who raise them for sale.

QUICKSAND, a loose sand into which a ship sinks by her own weight, as soon as the water retreats from her bottom.

QUICKSILVER. See **MERCURY**.

QUICKWORK, generally signifies all that part of a ship which is under water when she is laden; it is also applied to that part of the side which is above the sheer rail.

QUILLS, are the large feathers taken out of the end of the wings of geese, ostriches, crows, &c. They are denominated from the order in which they are fixed in the wing; the second and third quills being the best for writing, as they have the largest and roundest barrels. Crow quills are chiefly used for drawing.

QUILTING, a method of sewing two pieces of silk, linen, or stuff, on each other, with wool or cotton between them; by working them all over in the form of chequer or diamond work, or in flowers. The same name is also given to the stuff so worked.

QUILTING, the operation of weaving a kind of coating formed of the strands of ropes about the outside of any vessel, to contain water, as a jar, bottle, &c.

QUINCUNX, in Roman antiquity, denotes any thing that consists of five-twelfth parts of another, but particularly of the *as*, or pound.

QUINCUNX Order, in Gardening, a plantation of trees, disposed originally in a square, and consisting of five trees, one at each corner, and a fifth in the middle; or a quincunx is the figure of a plantation of trees, disposed in several rows, both length and breadthwise, in such a manner, that the first tree in the second row commences in the centre of the square formed by the two first trees in the first row, and the two first in the third, resembling the figure of the five at cards.

QUINDECAGON, in Geometry, a plane figure with fifteen sides and fifteen angles, which, if the sides are all equal, is termed a regular quindecagon, and irregular when otherwise. The side of a regular quindecagon inscribed in a circle is equal in power to the half-difference between the side of the equilateral triangle, and the side of the pentagon inscribed in the same circle; also the difference of the perpendiculars let fall on both sides, taken together.

QUINTAL, in Commerce, the weight of a hundred pounds.

QUINTESENCE, in the ancient chemistry, properly noted the fifth essence, or the result of five successive distillations. This term was also used to express the highest degree of rectification to which any substance could be brought. Of late years it has become partially obsolete.

QUIPOS, in literary history, a name given knots or cords of various colours in Peru, which imperfectly supplied the place of writing. The different colours denoted distinct objects, and each knot expressed a different number.

QUIRE, of **PAPER**, a quantity of 24 or 25 sheets.

QUITAM, in Law, is where an action is brought or an information exhibited, against a person, on a penal statute, at the suit of the king and the party or informer, when the penalty for breach of the statute is directed to be divided between them; in that case the informer prosecutes as well for the king as for himself.

QUIT-CLAIM, in Law, signifies a release of any action that one person has against another. It signifies also a quitting a claim or title to lands, &c.

QUIT-RENT, in Law, a small rent that is payable by the tenants of most manors, whereby the tenant goes quit and free from all other services. Anciently this payment was called white-rent, on account that it was paid in silver coin, and to distinguish it from rent-corn.

QUOIN, a wedge employed to raise the cannon to a proper level, that it may be more truly directed to the object. Also, a small wedge used by printers for fastening their pages in iron chases.

QUOINS, are also employed to wedge off casks of liquids from each other, that their bilges may not rub so as to occasion a leak by the agitation of the ship at sea.

QUOITS, a kind of exercise or game, known among the ancients under the name of *discus*.

QUO MINUS, is a writ which issues out of the court of exchequer to the king's farmer or debtor, for debt, trespass, &c. Though this writ was formerly granted only to the king's tenants or debtors, the practice now is become general for the plaintiff to surmise, that by the wrong the defendant does him, he is the less able to satisfy his debt to the king, by which means

jurisdiction is given to the court of exchequer to determine the cause. This writ is to take the body of the defendant, in like manner as the *capias* in the common pleas, and the writ of *latitat* in the king's bench.

QUORUM, a word which often occurs in our statutes, and is much used in commissions, both of justices of the peace and others, and so called from the words of the commission, *quorum unum esse volumus*, of whom we wish that A, B, &c. should be one. All magistrates are now of the quorum.

QUO WARRANTO, in Law, a writ which lies against a

person or corporation that usurps any franchise or liberty against the king; as to have a fair, market, or the like, in order to oblige the usurper to shew by what right and title he holds or claims such franchise. This writ also lies *formis-user* or non-user of privileges granted. The attorney general may exhibit a quo-warranto in the crown office against any particular persons, or bodies politic or corporate, who use any franchise or privilege without having a legal grant or prescription for the same, and a judgment obtained upon it is final, as being a writ of right.

R.

R A D

R, the seventeenth letter of our alphabet. In the notes of the ancients, R. or RO signifies Roma; R. C. Romana civitas; R. G. C. rei gerendæ causa; R. F. E. D. recte fractum et dictum; R. F. regis filius; R. P. res publica, or Romani principes; and R. R. R. F. F. res Romana ruet ferro, fame, flamma.

In the prescription of physicians, R or R, stands for recipe, i. e. take,

RABBIT, a deep groove or channel, cut in a piece of timber longitudinally, to receive, the edge of a plank, or the ends of a number of planks, which are to be securely fastened therein. The depth of this channel is equal to the thickness of the plank, so that when the end of the latter is let into the rabbit, it will be level with the outside of the piece. Thus the ends of the lower planks of a ship's bottom terminate upon the stem afore and the stern post abaft, with whose sides their surfaces are even. The surface of the garboard streak, whose edge is let into the keel, is in the same manner level with the side of the keel at the extremities of the vessel.

RABBETING, in Carpentry, the planning or cutting of channels or grooves in boards. In ship carpentry, it signifies the letting-in of the planks of the ship into the keel; which in the rake and run of a ship, is hollowed away, that the planks may join the closer.

RACE, a particularly strong tide or current.

RACK, an engine of torture furnished with pulleys and cords, &c. for extorting confession from criminals. This instrument is happily banished from almost all christian countries.

RACK, a frame of timber containing several sheaves, and usually fixed on the opposite sides of a ship's bowsprit, to direct the sailors to the respective ropes passing through it.

RACKING a Tackle, the fastening two opposite parts together with a seizing, so as that any weighty body suspended thereby shall not fall down, although the tackle-fall should be loosened by accident or inattention.

RADIAL CURVES, are curves of the spiral kind, whose ordinates, if they may be so called, all terminate in the centre of the including circle, appearing like radii of that circle; whence the name.

RADIANT POINT, or **RADIATING Point**, is any point from which rays proceed.

RADIATION, the act of a body emitting or diffusing rays of light all round, and from a centre.

RADICAL, that which is considered as constituting the distinguishing part of an acid, by its union with the acidifying principle, or oxygen, which is common to all acids. Thus sulphur is the radical of the sulphuric and sulphureous acids. It is called the base of the acid; but base is a term of more extensive application.

RADICAL Sign, (from *radix*, root,) in Algebra, is the character by which the root of a quantity is expressed, and is formed thus, $\sqrt{}$, while the particular root is indicated by a figure on the left of the sign: thus, $\sqrt[4]{a}$, $\sqrt[3]{a}$, \sqrt{a} , &c. denote the square root, cube root, and biquadratic root of the quantity *a*, or of any

R A G

other quantity placed under the like signs. When it is a compound quantity whose root is to be expressed, it is put in a parenthesis, and the sign prefixed; thus, $\sqrt[3]{a^3 + b^3}$ means the cube root of the sum of a^3 plus b^3 ; or it is otherwise indicated by a line thus, $\sqrt[3]{a^3 + b^3}$; the characteristic $\sqrt[3]{}$ is generally omitted in the square root, so that instead of writing $\sqrt[3]{a}$ for the square root of *a*, we merely write \sqrt{a} , by which the square root is always to be understood.

RADII, the plural of **RADIUS**.

RADIOMETER, a name sometimes given to the *Forx Staff*.

RADIUS, in Geometry, the semi-diameter of a circle, or a right line drawn from the centre to the circumference. It is implied in the definition of a circle, and it is apparent from its construction, that all the radii of the same circle are equal. The radius is sometimes called, in trigonometry, the *sinus totus*, or whole sine. The length of the radius of any circle is equal to that of an arc of 67.2957795 degrees of the same circle.

RADIX, the same as root, but used in a different sense by different authors; thus we say, *radix* of a system of logarithms, a system of notation, &c. meaning the fundamental quantity on which the system is constructed, or by which all the others are compared.

RADIX of a System of Logarithms, is that number which involved to the power, denoted by the logarithm of a number, is equal to that number. This radix in the Common, or Briggs's Logarithms, is 10, and in the Napierian or Hyperbolic Logarithms, it is 2.71828182 , &c. and generally the radix in any system of logarithms, is that number whose logarithm in that system is unity.

RADIX of a System of Notation, is that number which indicates the local value of the figures, and is in all systems represented by a unit and cipher (10), which is *ten* in the common system, *two* in the binary, *three* in the ternary, &c.

RADIX, is also used as a term of comparison between any finite function and its expansion or development; thus we know that $\frac{1}{1+r} = 1 - r + r^2 - r^3 + r^4 - \&c.$ in which case

$\frac{1}{1+r}$, is sometimes called the radix of the series $1 - r + r^2 - r^3 + r^4 - \&c.$

RAFT, a sort of float, formed by an assemblage of various planks or pieces of timber fastened together side by side, so as to be conveyed more commodiously to any short distance in a harbour or road than if they were separate.

RAFT Port, a square hole cut through the buttocks of some ships, immediately under the counter, to load or unload the planks and pieces of timber, which, on account of their great length, could not be got in or out otherwise.

RAFTERS, in Building, are pieces of timber, which, standing by pairs on the raising piece, meet in an angle at the top, and form the roof of a building.

RAGG, or **Rowly**, a genus of stones belonging to the siliceous class. It is of a dusky or dark gray colour, with many small

shining crystals, having a granular texture, and acquiring an ochry crust by exposure to the air.

RAIA, the *Ray*, in Natural History, a genus of fishes of the order cartilaginei. These fishes are found only in the sea, where they feed on whatever animal substances they meet with. They are sometimes of the weight of two hundred pounds. They conceal themselves for the greater part of the winter in the mud or sand of the bottoms, and, indeed, are seldom seen near the surface of the water. The female is larger than the male, and produces her offspring living, and only one at a time; the young extricating itself gradually from its confinement, and remaining some time attached by the umbilical vessels, after its complete appearance. There are nineteen species; the skate is one of the largest of the genus, weighing sometimes two hundred pounds, and one of the size is reported to have been served up at St. John's College, Cambridge; it is the most esteemed species of the genus. The thorn-back is much inferior to the skate in size and goodness. It is distinguished by its long and curved spines, on its upper surface. The above are rhomboidal. The sting-ray inhabits the Indian and Mediterranean seas, and its tail is armed with a very long serrated spine, with which it can inflict very formidable wounds, and which it casts off every year. This was formerly supposed to contain the most subtle poison. It injures, however, only by piercing and laceration; and to prevent this, the tail is almost always cut off as soon as the fish is caught. The torpedo inhabits the Mediterranean and the North seas, and grows to the weight of twenty pounds. This fish possesses a strong electrical power, and is capable of giving a very considerable shock through a number of persons forming a communication with it. This power was known to the ancients, but exaggerated by them with all the fables natural to ignorance, and it is only recently that the power was ascertained to be truly electric. It is conducted by the same substances as electricity, and intercepted by the same. In a minute and a half no fewer than fifty shocks have been received from this animal, when insulated. The shocks delivered by it in air are nearly four times as strong as those received from it in water. This power appears to be always voluntarily exercised by the torpedo, which occasionally may be touched and handled without its causing the slightest agitation. When the fish is irritated, however, this quality is exercised with proportional effect to the degree of irritation, and its exercise is stated in every instance to be accompanied by a depression of the eyes.

RAIL, or **WATER RAIL**, in Ornithology, the name of a bird of a long slender body, with short concave wings. The legs of this bird are placed very far behind, and are of a dusky flesh colour. Its toes are very long, and though the feet are not webbed, it takes the water, swims with ease, and is often observed to run apparently along its surface. It delights less in flying than in running, which it does very swiftly along the margins of brooks covered with rushes. In running, it occasionally flirts up its tail; and in flying, its legs hang down. Pennant says, that it is a unique species.

RAIL Land, in Ornithology, is a migrating bird. It has a short, strong thick bill, and is generally found among corn, grass, broom, or furze. It leaves this kingdom before winter. It abounds in Anglesea, where it appears about the middle of April, and is supposed to come from Ireland. Of the Hebrides and Orkneys it is generally an inhabitant.

RAILING, in Rural Economy, is a sort of fence constructed with posts and rails. It is frequently used to protect young hedge fences and trees from the depredations of cattle or other animals.

RAILLERY, Dr. Johnson has defined to be a slight satire or satirical merriment; and another writer has compared it to a light that dazzles, but does not burn. It is serious, severe, and good-humoured, and if it perplexes it should never offend.

RAILWAY, *Tram* or *Dram Road*, in Rural Economy, is a track constructed of wood, stone, or other materials, but chiefly of iron, upon the level surface of an inclined plane, or in other situations, for the purpose of diminishing friction, and for the more easy conveyance of heavy loads of any kind of articles. Until very lately, rail roads were chiefly confined to mines of various descriptions, but they are now coming into more general use, and are capable of being applied with advantage to many roads on which they have never yet made their appear-

ance. In Derbyshire, Shropshire, Lancashire, and several other counties, they are very numerous, some of them extending several miles. At first timbers were laid down, on which flat bars of iron were nailed. This was afterwards succeeded by cast iron of sufficient thickness, and the timber was dismissed. The benefits arising from these rail roads have given rise to numerous calculations. Dr. Anderson estimates, that upon a perfect level, one horse of moderate strength can draw with ease from twelve to twenty tons. On inclined planes, where the ends of canals cannot be brought to join the sea without many locks, they might be employed with the greatest success. Instead of loading any pair of wheels with an enormous weight which would tend to crush the road over which they pass, it has been found by experience more beneficial to employ a string of carriages, that the pressure may be distributed. Near Colebrook Dale there is a rail road, on which loaded boats are drawn up to a canal two hundred and twenty feet above the level of the Severn, and let down into it in a similar manner, by which means twenty-two locks are saved, and the work is executed in a more expeditious manner. This is supposed to be the greatest inclined plane in Europe, or perhaps in the world; for though they are much used in China in the place of locks, none of them are equal in height and acclivity to this.

RAIN. This phenomenon some philosophers have attributed entirely to the influence of the electric fluid, and this explanation has been rendered the more probable by the circumstance of most abundant showers usually accompanying a thunder storm. It is worthy observation, that much the greatest quantity of rain falls in that time of the year when the air appears clearest, and when, from the heat, the appearance of moisture on the ground soon disappears; also, that in warmer countries than ours, and where the air appears much clearer, the quantity of rain which falls greatly exceeds that in this country. Very frequently rain is produced by the concussion or condensation of two clouds, the one positively and the other negatively electrified; and this has been proved by experiment with a kite elevated to a great height in the air. There is no necessity to maintain that rain can never be produced in any other manner. The mean annual quantity of rain is greatest at the equator, and decreases gradually as we approach the poles. Thus, at Grenada, West Indies, it is 126 inches; Cape Francois, 120; Calcutta, 81; Rome, 39; England, 35; Petersburg, 16.

The number of rainy days is smallest at the equator, and increases in proportion to the distance from it. The mean number from north latitude 12° to 43°, being 78; from 43° to 46°, being 103; from 46° to 50°, being 134; from 51° to 60°, 161. The number of rainy days is often more in winter than in summer; but the quantity of rain is greater in summer than in winter. According to an observation made in England, if two vessels of equal extent be exposed at different heights, and the quantity of water which falls into them during any considerable time, for instance, a year, be measured, it is found that the vessel at the greater height receives less water. This seems to point out that the drops of rain become larger as they fall, by the precipitation of the watery vapours which they encounter; and that in lowering the temperature of the space which they traverse, they cause these vapours to precipitate more abundantly. This experiment, repeated at the observatory at Paris, gave the same result. A necessary consequence is, that, in general, more rain falls in the valleys than on the hills.

The quantity of rain which has fallen in different places has been accurately observed, and from which it appears, that much depends upon local situation. The quantity of rain which fell at Paris in the course of a year, taken at a medium of six years, was 20.19 inches; and in London, the medium quantity per annum, for the same number of years, was 23.001. Much, however, depends upon the height of the rain-gage from the surface of the earth, more than upon the comparative altitudes of it with reference to the surface of the sea, or any fixed point; the rain-gage on the top of a mountain, giving nearly as much as that in the plain beneath; whereas, one gage placed on the top of a house or church, and another below, give very different quantities. The following table exhibits the results of several very accurate observations made on three gages, one at the bottom of a house, another at the top of the

and a third on Westminster Abbey, the greatest care taken that none of the water should evaporate after it the gage, by passing it through a narrow tube into a well stopped below.

These results it will appear, that there fell below the house above a fifth part more rain than what fell in the space above the top of the same house. And that there a Westminster Abbey not much above half what was a fall in the same space below the tops of the houses. Experiment has been repeated in other places with the result; and, notwithstanding the cause of this extraordinary difference has not yet been discovered, it is at the same time useful to be apprised of it, to prevent any inaccurate conclusion from a comparison of different gages.

Quantity of Rain which fell in London from July 7, to July 6 in the succeeding Year.

MONTHS.	Lower Gage of a House.	Middle Gage, Top of a House.	Upper Gage on Westminster Abbey.
	<i>Inches.</i>	<i>Inches.</i>	<i>Inches.</i>

Oct. 17 to 22,	1.281	1.388
Oct. 22 to 29,		
	8.766	8.165

These experiments justify the assertion made above, viz. that a quantity of rain, in any place, depends principally on the altitude above the surface of the earth, and not much on the comparative altitude of two places with regard to the surface of the sea, and consequently not upon the rarity or density of the atmosphere, as was for a long time supposed by philosophers.

Rainbow. The rainbow is a circular image of the sun, coloured. It is thus produced; the solar rays, entering drops of falling rain, are refracted to their farther surface, thence by one or more reflections transmitted to the eye at their emergence from the drop, as well as at their

entrance, they suffer a refraction, by which the rays are separated into their different colours, and thus, therefore, are exhibited to an eye properly placed to receive them. That this is the true account of the formation of the rainbow, appears from the following considerations. 1. That a bow is never seen but when rain is falling, and the sun shining at the same time, and that the sun and bow are always in opposite quarters of the heavens; this every one's experience can testify. 2. That the same appearance can be artificially represented by means of water thrown into the air, when the spectator is placed in a proper position with his back turned to the sun:

Let AB be a drop of water, and CD a pencil of solar rays incident thereon; if all the rays of any one colour, as red, belonging to the pencil CD, be refracted to the same point G, and thence reflected, they will fall on the space RQ, with the same obliquity and at the same distances from each other, as the refracted rays, if proceeding backward from G, would fall on the space TS; but these at their refraction would emerge into TD, CS, &c. parallel to each other, and therefore will enter an eye properly placed copiously enough to cause a sensation; a red colour will therefore appear in the direction of these rays, and so of others. But if the refracted rays do not meet in the same point, the reflected rays will not fall on the surface, at the same distance from each other, as PT and IS do, though their obliquity to the surface be equal to that of the latter: therefore the refracted rays will emerge, diverging from each other, and consequently will not enter the eye copiously enough to cause a perception of their colour. It is plain that where the rays of any colour emerge parallel, all these emerging rays will be inclined to the incident rays in the same angle. And by calculation it is found, that the red rays when they emerge parallel to each other, make with the incident rays an angle, ABO, of $42^{\circ} 2'$, and the violet an angle, ACO, of $40^{\circ} 17'$, and the rays of the other colours angles greater than the latter, and

less than the former. If through the eye which receives the emerging rays, there be drawn a line AX, parallel to the incident rays, it will make with the emerging rays of each colour, angles RAX, and VAX, &c. equal to the above. This line AX is called the axis of vision. The several drops placed in the lines AR, AV, &c. will exhibit to the eye at A, the several prismatic colours respectively, as appears from what has been said; and if those lines be supposed to revolve with a conical motion round the axis of vision, it is evident for the same reason, that all the drops placed in each of the conic surfaces so generated, will transmit the rays of each colour respectively to the eye, and therefore that a number of circular concentric arches of the prismatic colours adjoining to each other, will be exhibited to the eye. This explanation relates to the interior bow, whose colours beginning from the outside, are red, orange, &c. as in the prismatic spectrum, which bow can never be seen if the sun be elevated more than $42^{\circ} 2'$ above the horizon; for the horizon HO always makes with the axis of vision, AX, an angle equal to the elevation of the sun; therefore in the case here stated, the line AQ, marking the vertex of a rainbow, would fall entirely below the horizon. As the interior bow is formed by one reflection and two refractions, so the exterior bow is formed by two reflections and two refractions, at the surfaces of the drops of falling rain. If the red ray of any

10 M

pencil, CD, of solar rays, after refraction, intersect each other at R, so that when reflected at T V, they may proceed parallel within the drop, after a 2d reflection at X Q, they will proceed to L M, intersecting each other at S, equally distant from X Q, as R is from T V, and as the rays Q T, X V, if they proceeded backward, would after reflection so fall on the surface, N O, as to be refracted into air parallel to each other; so X M, Q L, falling on the surface precisely in the same circumstance, shall be refracted to the eye parallel to each other, and therefore will enter it copiously enough to cause a perception of their colour, (and so of the rest). The red rays, when emerging parallel after two reflections, are by calculation found to make with the incident rays, and therefore with the axis of vision, an angle of $54^{\circ} 7'$. The violet rays, when emerging parallel, are found to make with their incident rays, and therefore with the axis of vision, an angle of $54^{\circ} 7'$; the other emerging rays meet the axis of vision in the intermediate angles. And hence it is easy to explain the generation of the exterior bow in the same manner as that of the interior. It is to be remarked, that the order of colours in the exterior bow is the reverse of that in the interior, and the reason of this appears in the above explanation. For A B, 3d figure above, which marks the direction of the violet rays in the outer bow, contains with A X, the axis of vision, a greater angle than A D, (which marks the direction of the red rays,) contains with the same axis. And the reverse is the case in the interior bow. It is evident, (for a reason similar to that given in the case of the interior bow) that an exterior bow cannot be seen when the elevation of the sun is above $54^{\circ} 7'$.

Lunar RAINBOW. An iris formed by the refraction of the moon's rays, in drops of rain, in the night-time.

Marine RAINBOW, the Sea Bow, is a phenomenon sometimes observed in a much agitated sea, when winds, sweeping part of the tops of the waves, carry them aloft, so that the rays of the sun are refracted, &c. as in a common shower.

RAINGAGE, or PLUVIOMETER, a machine for measuring the quantity of rain that falls. There are various kinds of rain-gages; that used at the apartments belonging to the Royal Society at Somerset-house, is thus described:—The vessel that receives the rain is of a conical form, strengthened at the top by a brass ring twelve inches in diameter. The sides of the funnel and inner lip of the brass ring are inclined to the horizon in an angle of more than 65° , and the outer lip in an angle of more than 50° , which are such degrees of steepness, that there seems no probability either that any rain which falls within the funnel, or on the inner lip of the ring, shall dash out, or that which falls on the outer lip shall dash into the funnel. The annexed figure represents a rain-gage of the best construction. It consists of a hollow cylinder, having within it a cork ball attached to a wooden stem, which passes through a small opening at the top, on which is placed a large funnel. When this instrument is placed in the open air in a free place, the rain that falls within the circumference of the funnel will run down into a tube, and cause the cork to float; and the quantity of water in the tube may be seen by the height to which the stem of the float is raised. The stem of the float is so graduated as to shew, by its divisions, the number of perpendicular inches of water which fell on the surface of the earth since the last observation. It is hardly necessary to observe, that after every observation the cylinder must be emptied.

A very simple rain-gage, and one which answers all practical purposes, consists of a copper funnel, the area of whose opening is exactly ten square inches; this funnel is fixed in a bottle, and the quantity of rain caught is ascertained by multiplying the weight in ounces by 173, which gives the depth in inches and parts of an inch. In fixing these gages, care must be taken that the rain may have free access to them; hence, the tops of buildings are usually the best places. When quantities of rain collected in them at different places are compared, the instruments ought to be fixed at the same heights above the ground at both places, because, at different heights, the quantities are always different, even at the same place. See RAIN.

RAISING a Purchase, the act of disposing certain instruments or machines, in such a manner as that, by their mutual efforts, they may produce a mechanical force sufficient to overcome the weight or resistance of the object to which this machinery is applied.

RAISINS, grapes prepared by suffering them to remain on the vine till they are perfectly ripe, and then drying them in the sun, or by the heat of an oven. The difference between raisins dried in the sun, and those dried in ovens, is very obvious: the former are sweet and pleasant; but the latter have a latent acidity with the sweetness, that renders them much less agreeable.

RAIT, in Rural Economy, a term used to signify the process or operation of dissipating the sap of vegetables by exposure to moisture, or the influence of the atmosphere. It is sometimes applied to hay when it has been much exposed to the alternations of wet and dry weather, but more particularly to hemp and flax. The process of raiting requires much nicety, its design being to detach the covering or bark of hemp and flax from the stalk, by spreading the plants thinly upon some grassy surfaces, or putting them into water during a given time for the same purpose.

RAKE, in Agriculture, a tool of the tooth kind, made use of for many purposes of husbandry, as for collecting together hay, corn, stubble, roots, leaves, and other similar materials. Of this implement there are many descriptions.

RAKE, the projection of the upper parts of a ship at the height of the stem and stern, beyond the extremities of the keel; thus, if a plummet is hung from the top of a ship's stern, so as to be level with the continuation of the keel, the distance between the after-end of the keel and the plummet will be the length of the rake of the stern.

RAKE, is also applied to the masts when they are out of a perpendicular situation, as, that ship's mainmast rakes aft.

RAKING, the act of cannonading a ship on the stern or head, so as that the balls shall range the whole length of the decks, which is one of the most dangerous incidents that can happen in a naval action; this is frequently called raking fore and aft, and is similar to what is termed by engineers enfilading.

RAKE, or Vein, in Geology, is the most common repository of metallic ores. These veins intersect mountains sometimes nearly in a vertical manner, but more generally with a greater or less degree of inclination from a perpendicular.

RALLYING, in War, re-assembling or calling together troops broken and put to flight.

RAM, in Hydraulics, is a machine for raising water to any given height, by means of the momentum of a stream of water flowing through a pipe. The passage of the pipe being stopped by a valve, which is raised by the stream as soon as its motion becomes sufficiently rapid, the whole column of water concentrates on the valve, and acts as a single solid, so that it must resist any pressure. Now if the valve open into a pipe leading to an air vessel, a certain quantity of water will be forced into it, so as to condense the air more or less rapidly, to the degree that may be required for raising a portion of the water contained in it to any given height.

Ram, in Mythology, the name of the highest god among the Gentiles.

RAM, Battering, in Artillery, is a military engine with an iron head, resembling that of a ram, much used by the ancients to batter and break down the walls of places besieged; but since the invention of cannon, this once formidable instrument has been dismissed from service. Battering rams were of three kinds; the first rude and plain, the others artificial and compound. The first appears to have been nothing more than a huge beam headed with iron, with which men by mere muscular force assailed a wall, and yet produced but little effect. Josephus describes a second sort of battering ram, as resembling the mast of a ship suspended horizontally in the middle by ropes fastened to another beam above, which is fixed on posts for its support. Thus balanced, it is swung by a number of men, in proportion to its weight, with its head violently against the wall, from which it recoils, and becomes prepared for another stroke. Scarcely any building could resist the tremendous blows of this machine. The third sort differed from the second only by having covering for the soldiers, to guard them against mis-

miles thrown from the walls. Some of these destructive instruments were suspended in a frame mounted on wheels for their more easy conveyance from place to place; and we are informed by Plutarch and Vitruvius, that they varied in length from 80 to upwards of one hundred feet; and while from the effects the largest have been known to produce, modern calculators have estimated their weight at more than three hundred tons. So late as the fourteenth century the ram was much in use. It was employed by Sir Christopher Wren in demolishing the walls of the old church of St Paul's, in order to his erecting the present structure, and was found to be an excellent machine for the completion of his purpose. See **BATTERING Ram**.

RAMA, in Hindoo Mythology, the name of a celebrated mortal, in whom their deity Vishnoo was incarnated for the purpose of relieving mankind from the oppression of Ravana, the malignant king of Lanka or Ceylon.

RAMADAN, a sort of lent observed among the Mahometans with great rigour, during which they fast the whole day from the first appearance of a new moon until the next new moon appears. To make amends for this abstinence, their nights are spent in riot and dissipation.

RAMAYANA, the title of a poem in Sanscrit, of great celebrity in India, regarded as sacred by some sects, and greatly venerated by all.

RAMI, in Hindoo Mythology, one of the many names of the goddess Parvati.

RAMMER, is a cylindrical block of wood nearly fitting the bore of a cannon, and fastened on a wooden staff, or on a stiff rope well served with spun yarn. It is used to drive the charge of a cannon home, or to the innermost part of it. The rope-rammers are most general in ships of war.

RAMPART, in Fortification, a massy bank or elevation of earth raised above the body of a place, to shelter those within from the direct fire of the enemy.

RAMPHASTOS, the *Toucan*, &c. a genus belonging to the order of piceæ. The bill is very large, and serrated outwardly. The nostrils are situated behind the base of the beak; and in most of the species the feet are toed, and placed two forwards and two backwards. The tongue is long, narrow, and feathered on the edges. Mr. Latham enumerates 15 different species.

RAMPHOID, a particular point of retrogression.

RAMSDEN'S MACHINE for dividing *Mathematical Instruments*, is a useful invention, by which these divisions can be performed with exceedingly great accuracy, such as would formerly have been deemed incredible. On discovering the method of constructing this machine, its inventor, Mr. Jesse Ramsden, received £615 from the commissioners of longitude; engaging himself to instruct a certain number of persons, not exceeding ten, in the method of making and using this machine from the 28th of October, 1775, to 28th of October, 1777; also binding himself to divide all octants and sextants by the same engine, at the rate of three shillings for each octant, and six shillings for each brass sextant, with Nonius's divisions to half-minutes, for as long time as the commissioners should think proper to let the engine remain in his possession. Of this sum of £615 paid to Mr. Ramsden, £300 were given him as a reward for the improvement made by him in discovering the engine, and the remaining £315, for his giving up the property of it to the commissioners.

This engine consists of a large wheel of bell metal, supported on a mahogany stand, having three legs, which are strongly connected together by braces, so as to make it perfectly steady. On each leg of the stand is placed a conical friction-pulley, whereon the dividing wheel rests: to prevent the wheel from sliding off the friction pulleys, the bell metal centre under it turns in a socket on the top of the stand. The circumference of the wheel is ratched or cut into 2160 teeth, in which an endless screw acts. Six revolutions of the screw will move the wheel a space equal to one degree. Now, a circle of brass being fixed on the screw arbor, having its circumference divided into 60 parts, each division will, consequently, answer to a motion of the wheel of 10 seconds, six of them will be equal to a minute, &c. Several different arbors of tempered steel are truly ground into the socket in the centre of the wheel. The upper parts of the arbors that stand upon the plane are turned of various sizes, to suit the centres of different pieces of work

to be divided. When any instrument is to be divided, the centre of it is very exactly fitted on one of these arbors; and the instrument is fixed down to the plane of the dividing wheel, by means of screws, which fit into the holes made in the radii of the wheel for that purpose. The instrument being thus fitted on the plane of the wheel, the frame which carries the dividing point is connected at one end by finger screws, with the frame which carries the endless screw; while the other end embraces that part of the steel arbor which stands above the instrument to be divided, by an angular notch, in a piece of hardened steel; by this means both ends of the frame are kept perfectly steady, and free from any shake. The frame carrying the dividing point or tracer, is made to slide on the frame which carries the endless screw to any distance from the centre of the wheel, as the radius of the instrument to be divided may require, and may be there fastened by tightening two clumps; and the dividing point or tracer being connected with the clumps by the double-jointed frame, admits a free and easy motion towards, or from, the centre for cutting the divisions, without any lateral shake. From what has been said, it appears, that an instrument thus fitted on the dividing wheel, may be moved to any angle by the screw and divided circle on its arbor, and that this angle may be marked on the limb of the instrument with the greatest exactness by the dividing point or tracer, which can only move in a direct line tending to the centre, and is altogether freed from those inconveniences that attend cutting by means of a straight edge. This method of drawing lines will also prevent any error that might arise from an expansion or contraction of the metal during the time of dividing.

RAMUS, PETER, a celebrated French mathematician and philosopher, was born in 1515, and fell a sacrifice to his religious opinion, on the massacre of St. Bartholomew's day, 1572, in his 57th year. He was author of several works relating to mathematical subjects.

RAN, twenty cords of twine wound on a reel, every cord so parted by a knot as to be easily separated.

RNA, the *Frog*, in Natural History, a genus of Amphibia of the order of Reptiles. There are thirty-six species, of which the following deserve the chief attention:—The common toad, is found in shady and damp situations throughout Europe, and often is met with in cellars. In spring it moves towards the water, and lays its ova in a brilliant band of glutinous substance, several feet in length. The ova appear like heads of jet, and in fourteen days these convolved larvae are developed and swim about, nourishing themselves by insects and vegetable substances, till their tail disappears, and their legs are formed, and they pass from water to land. The toad is always covered with tubercles, is generally of a dark brown colour above, and a light yellow on the lower parts both of the body and limbs. It lives to a considerable age, surviving in many instances even twenty years; and the case of a toad, which arrived at the age of forty, is mentioned by Mr. Pennant. The ides formerly entertained of venomous qualities possessed by this animal, are now ascertained to be well founded, as Sir H. Davy has found, on dissection and analysis, venomous matter contained in follicles in the *cutis vera*, round the head, and even on the extremities.—Statements have often been published of toads found living in large blocks of wood and of stone, with no perceivable inlet for the air, and touched on all sides by the substance in which they were enclosed. It is ascertained that a toad will live for many weeks, and even months, in a very small case, or under a pan, buried deeply in the earth. The eyes of the toad are remarkable for their clearness and beauty, and excite sensations of a very different nature from that disgust, and even horror, which its general appearance almost universally excites. The Surinam toad, much larger than the common toad, being sometimes seven inches in length, is almost equally loathsome with the last, and is distinguished particularly by that curious deviation from the general course of nature, the exclusion of its young from its back, which contains a variety of cells for their residence, and a certain degree of maturation. The common frog, is met with almost every where throughout Europe, in low and wet situations, where it can procure that food on which it principally subsists, worms and insects. The green frog, is much larger than the last species, and abounds in many countries in Europe, though but

rarely to be found in England. They are in some places much used for food, particularly in France, and thought fittest for the table in the month of June. The bull-frog, is found in many regions of North America, and grows to the length of eighteen inches from the nose to the hind feet. Its sounds resemble the lowing of a bull. They are highly rapacious, often commit great depredations on the poultry, swallowing even young geese without considerable difficulty. The tree frog, is not found in Great Britain, but is met with in various other parts of Europe, and in elegance and activity is superior to every other European species. In summer it resides in the woods, and haunts the trees in quest of insects, which it approaches on its belly, in the same manner as a cat to a mouse, and at length seizes with an elastic and instantaneous spring. It is particularly noisy on the approach of rain. In winter it takes up its abode in the bottom of the waters, remaining till the spring in a state of torpor.

RANCIDITY, in Chemistry. Fixed oils are liable, by keeping, to undergo a change well known by the name of rancidity. They become thick, acquire a brown colour, an acid taste, and a disagreeable smell. The oil thus altered converts vegetable blues into red, and of course contains acid.

RANDOM SHOT, in Gunnery, is a shot made when the muzzle of a gun is raised above the horizontal line, and is not designed to shoot directly or point-blank. The utmost random of any piece is about ten times as far as the bullet will go point-blank.

RANELAGH *Rotunda and Gardens*, near Chelsea, built and opened for musical performances in 1742. Degenerating into a scene of licentiousness, it was shut up in 1803, since which the buildings have been wholly demolished.

RANGE, in Gunnery, the path of a bullet, or the line it describes from the mouth of the piece to the point where it lodges.

RANGE, a sufficient length of the cable drawn upon the deck before the anchor is let go, that, by its sinking to the bottom without being interrupted, the flukes may be forced deeper into the ground; therefore the range drawn up out of the tier ought to be equal in length to the depth of the water where the ship anchors.

RANGE, is also the distance to which a bomb or cannon ball is thrown from a piece of artillery by the explosion of gunpowder. The flight of a shot is distinguished by artillery men into two different ranges, of which the first is called the point-blank, and the second the random shot; to these also may be added the ricochet, or rolling and bounding shot. The point-blank range is the extent of the apparent right line described by a ball discharged from a cannon. The random shot is, when, by letting the breach down upon the bed of the carriage, the ball is carried to its greatest possible distance, and describes a curve in its flight. The ricochet is fired by elevating the piece from three to six degrees, and only charging it with a quantity of powder sufficient to carry the shot along the face of the works attacked; the shot, thus discharged, so as to go just over the parapet, rolls, and bounds about, killing, maiming, or destroying all it meets in its course, creating much more disorder by going thus slowly, than if thrown from the piece with greater violence. As one of the effects of the bomb results from its weight, the range of mortars is extremely different from that of cannon, because the former is not pointed at a certain object like the latter, but inclined to the horizon at a certain angle, so that the bomb being thrown up obliquely, may fall upon the place intended; hence it appears, that the mortar has no point-blank range, or at least that no use is made of it. To make a bomb fall on a given place, two things are to be considered, viz. the elevation of the mortar, and the quantity of powder used to charge it: respecting the former, a bomb will be thrown to the greatest distance when the elevation of the mortar is 45 degrees, it being the half of 90 degrees, or a right angle, that is equally distant from the horizon and the zenith; hence it follows, that if a mortar is elevated any number of degrees above 45, it will throw the shell to the same distance as if depressed an equal number of degrees below 45: where weight is required, as for the destruction of any building, the mortar should be elevated as much as possible for the distance, but when the business is to fire on a body of men, it must be

pointed as much below 45, that the bomb may not have force to penetrate far into the ground, and the splinters in the explosion may do more execution. Ricochet signifies duck and drake, a name given to the bounding of a flat stone thrown almost horizontally into the water.

It was the opinion of engineers formerly, that by charging the pieces high, the ball was thrown to a greater distance. Hence the pieces were charged with two-thirds, or even the whole weight of the shot, in order to impel it with greater velocity; but it has been discovered since, that the half or one-third of the weight of the ball is the fittest charge for the piece. It may not be amiss to observe here, that the range of cannon is greater in the morning and at night, than at noon; and is cold, than in hot weather. The reason is, that at these times the air being less heated, gives less way to the dilatation of the powder, which being, by these means, confined as it were to a smaller sphere of action, must have a stronger effect in propulsion. When the lengths of cannon are proportionable to the height of the charge, the shot will be discharged with the same velocity, whatever the calibre may be. The greatest distance to which a shell can be thrown, with the strongest charge, is little more than about 1800 or 2000 fathoms. See GUNNERY.

To RANGE, is to sail in a parallel direction, and near to, as, "we ranged the coast;" "the enemy came ranging up along side of us."

RANGER, a sworn officer of a forest, appointed by the king's letters patent, whose business is to walk through his charge, to drive back the deer out of the purviews, &c. and to present all trespasses within his jurisdiction at the next forest court.

RANGES, in a ship, two pieces of timber that go across from side to side: the one on the fore-castle, a little abaft the foremast; and the other in the beak-head, before the woudings of the bowsprit.

RANK, in War, is a row of soldiers placed side by side.

RANK, the order or place assigned a person suitable to his quality or merit.

RANSOM, a sum of money paid for the redemption of a person out of slavery, or for the liberty of a prisoner of war.

RANT, an extraordinary flight of passion, overshooting nature and probability. It is sometimes introduced into the drama, and occasionally into the pulpit.

RANUNCULUS, a genus of the polyandria class, and polygynia order; in the natural method ranking in the 26th order, multisiliquæ. A well-known garden flower, of which there are many species. The Persian Crowfoot, or Garden Ranunculus, is the most noted.

RAPE, in Law, is where a man has carnal knowledge of a woman by force, and against her will; by 18 Eliz. c. 7, if any person shall unlawfully and carnally know and abuse any woman-child under the age of ten years, whether with her consent or against it, he shall be punished as for a rape. And it is not a sufficient excuse in the ravisher, to prove that she is a common strumpet; for she is still under the protection of the law, and may not be forced. Nor is the offence of a rape mitigated by shewing that the woman at last yielded to the violence, if such her consent was forced by fear of death or duress; nor is it any excuse that she consented after the fact. 1 Haw. 108.

RAPE, is also a name given to a division of a county, and sometimes means the same as a hundred, and at other times signifies a division consisting of several hundreds.

RAPE, in Gardening, the common name of a plant of the cabbage kind.

RAPE, in Agriculture the name of a plant much cultivated for its seed, and also as a green food for cattle and sheep.

RAPE Oil, an oil obtained by means of expression from the seeds of the above plant, in mills constructed for the purpose. The refuse is valuable as manure.

RAPHANUS, *Radish*, a genus of the siliquosa order, in the tetradynamia class of plants; and in the natural method ranking under the 39th order, siliquosa. The calyx is close: the siliqua torose, or swelling out in knots, sub-articulated, and round. There are two melliferous glandules between the shorter stamina and the pistil, and two between the longer stamina and the calyx. There are six species.

RAPIDS, Boat for passing up. The American papers contain some remarkable accounts of a newly invented boat, which has been brought into operation on the rapids of the Delaware, which ascends against the stream, and tows up ordinary boats, heavily laden, with it. The plan seems to be this:—The anchor is dropped at the head of the rapid to be passed, to which is connected a rope, extending to the termination of the rapid; here a boat is provided, crossed by a shaft, to which is attached wheels with floats or paddles, of a width in proportion to the power required; on this shaft is a windlass, or drum, around which the rope is passed, and thence, over the stern of the boat, into the water; thus arranged, the boat is pushed into the rapid; and the current, acting with all its strength upon the floats, and they presenting to the stream a much greater surface and resistance or hold for the water than the prow of the boat, the wheels are turned by the current, which, winding up the rope, draws the boat irresistibly to the anchor at the head of the rapid. The boat has been found to ascend one-half faster than the current flows down, and to be capable of towing up whatever may offer itself.

The boat, having thus performed its voyage, its appendages are disengaged, it is dropt down with the current, and is then ready again for another trip up the rapid. A correspondent of the *New York Evening Post* says:—"I had the pleasure a few weeks since, of witnessing the first experiment of the boat at that place, (opposite Trenton on the Delaware,) and was much surprised that an invention of such great utility had not before been put in operation. There can be no doubt as to the practicability of the plan, and the competency of the power to be acquired for propelling heavy laden boats against rapids; for in the experiment I witnessed, there was towed up at the same time, a large Durham boat, two batteaux, and twelve persons! The Durham boat was old and leaky, and drew as much water as if loaded with three or four tons; and she ascended the rapids, (which run at about the rate of ten knots,) with as great rapidity apparently as when without any encumbrance. Many of our valuable rivers have not heretofore been navigated on account of obstructions in them by rapids, which have been insurmountable; but by the invention of Col. Clarke, such difficulties no longer exist. Much credit is certainly due to him for the invention, as it promises to be of the greatest utility to this country in the navigation of our rivers; and it is presumed that his plan will ere long be brought into general use throughout the United States."

RAPIER, formerly meant an old-fashioned cutting sword, but in the more modern sense it signifies a small sword, as contradistinguished from a cutting sword.

RAPINE, in Law. To take a thing in private against the owner's will is theft; but to take it openly, or by violence, is rapine or robbery.

RAPISTRUM, in Botany, the wild turnip, so called from its affinity to Rapa, the cultivated one. It sometimes signifies a species of the sea cabbage.

RAPTURE, an ecstasy or transport of mind.

69.

RAPUNCULUS, in Botany, a root formerly much cultivated, but at present very little known. Its name is derived from the resemblance which the root bears to an oblong turnip.

RARA AVIS, in Ornithology, the name of a bird common about the lakes and rivers of America. It is of the kingfisher kind, but nearly as large as a duck, black on the crown, but white on the breast and belly.

RARE, in Physics, a relative term, the reverse of dense, being used to denote a considerable porosity, or vacuity between the particles of a body; as the word dense implies a contiguity or closeness of the particles.

RAREFACTION, in Physics, is the making a body to expand, or occupy more room or space, without the accession of new matter. It is by rarefaction that gunpowder takes effect; and to the same principle also we owe collicles, thermometers, &c. The degree to which air is rarefiable, exceeds all imagination; perhaps, indeed, its degree of expansion is absolutely beyond all comprehensible limits. Upon the rarefaction of the air is founded the method of measuring altitudes by the barometer; in all cases of which, the rarity of the air is found to be inversely as the force that compresses it, or inversely as the weight of all the air above it at any place.

The open air, in which we breathe, says Sir Isaac Newton, is 8 or 900 times lighter than water, and by consequence 8 or 900 times rarer. And since the air is compressed by the weight of the incumbent atmosphere, and the density of the air is proportionable to the compressing force, it follows, by computation, that at the height of about seven English miles from the earth, the air is four times rarer than at the surface of the earth; and at the height of 21, 28, or 35 miles, it is respectively 64, 256, or 1024 times rarer, or thereabouts; and at the height of 70, or 140, and 210 miles, it is about 1,000,000, 1,000,000,000,000, or 1,000,000,000,000,000,000, &c.

Mr. Cotes has found, from experiments made with a thermometer, that linseed oil is rarefied in the proportion of 40 to 39 with the heat of the human body; in that of 15 to 14, with that degree of heat wherein water is made to boil; in the proportion of 15 to 13 in that degree of heat wherein melted tin begins to harden; and finally, in the proportion of 23 to 20, in that degree wherein melted tin arrives at a perfect solidity. The same author discovered, that the rarefaction of the air, in the same degree of heat, is ten times greater than that of linseed oil; and the rarefaction of the oil about fifteen times greater than that of the spirit of wine.

RARITY, lightness, thinness, the reverse of density.

RAT. See Mice.

A Simple Rat Trap.—Let a cask, ingeniously placed, be half filled with water, and let a false top, or lid, be nicely balanced about two inches below the edge of the mouth; in the middle of the lid let some wholesome meat be fastened, (as rats are very nice,) so that, the moment one of them sets foot upon the edge, it may be precipitated into the water below; and, as the lid immediately resumes its position, the victim is secured, and a second, a third, or a fourth, may be successively secured and destroyed.

RATAFIA, a spirituous liquor, prepared from the kernels, &c. of several kinds of fruit, particularly of cherries and apricots. Ratafia of cherries is prepared by bruising the cherries, and putting them into a vessel wherein brandy has long been kept; then adding to them the kernels of cherries, with straw-berries, sugar, cinnamon, white pepper, nutmegs, cloves; and to twenty pounds of cherries, ten quarts of brandy. The vessel is left open ten or twelve days, and then stopped close for two months before it is tapped. Ratafia of apricots is prepared two ways, viz. either by boiling the apricots in white wine, adding to the liquor an equal quantity of brandy with sugar, cinnamon, mace, and the kernels of apricots; infusing the whole for eight or ten days, then straining the liquor, and putting it up for use; or else by infusing the apricots cut in pieces in brandy, for a day or two, passing it through a straining bag, and then putting in the usual ingredients.

RATCH, or **Risu**, in Clock-work, a sort of wheel having twelve fangs, which serves to lift up the detents every hour, and make the clock strike.

RATCHETS, in a watch, are the small teeth at the bottom of the fuser, or barrel, which stops it in winding up.

10 N

RATE, the order or classes into which the ships of war are divided in the navy, according to their force and magnitude; thus, the

First Rate, comprehends all ships of one hundred guns and upwards, having 42 pounders on the lower deck, 24 ditto on the middle deck, 12 ditto on the upper deck, and 6 ditto on the quarter deck and fore-castle. They are manned with 850 to 875 men, including their officers, seamen, marines, servants, &c.—N. B. In general the ships of every rate besides the captain, have the master, the boatswain, the gunner, the chaplain, the purser, the surgeon, and the carpenter; all of whom except the chaplain have their mates or assistants, in which are comprehended the sail-maker, the master at arms, the armourer, the captain's clerk, the gunsmith, &c. The number of other officers are always in proportion to the rate of the ship. A first rate has 6 lieutenants, 6 master's mates, 24 midshipmen, and 5 surgeon's mates, who are considered as gentlemen; besides the following petty officers, quarter-masters and their mates, 14; boatswain's-mates, and yeomen, 8; gunner's mates and assistants, 6; quarter-gunnery, 25; carpenter's-mates, 2, besides 14 assistants; 1 steward's-mate to the purser, &c.

Second Rate, includes all ships carrying from 90 to 98 guns upon three decks, of which those on the lower battery are 32 pounders; and those on the middle 18 ditto; on the upper deck 12 ditto, and those on the quarter-deck 6 ditto; which usually mount to 4 and 6; their complement of men is from 700 to 750, in which are 6 lieutenants, 4 master's-mates, 24 midshipmen, and 4 surgeon's mates; 14 quarter-masters, and their mates, 6 boatswain's mates and yeomen; with 22 quarter-gunnery, 2 carpenter's-mates, with 10 assistants, and 1 steward, and 1 steward's mate.

Third Rate, consists of ships from 64 to 80 cannon, which are 32, 18, and 9 pounders. The 80 gun-ships, however, begin to grow out of repute, and give way to those of 74, 70, &c. which have only two whole batteries, whereas the former have three, with 28 guns planted on each, the cannon of their upper deck being the same as those on the quarter deck and fore-castle of the latter, which are 9 pounders. The complement in a 74 is 650, and in a 64, 500 men; having in peace 4 lieutenants; but in war, 5; and when an admiral is aboard, 6. They have 3 master's-mates, 16 midshipmen, 3 surgeon's-mates, 10 quarter-masters and their mates, 6 boatswain's mates and yeomen, 4 gunner's mates and yeomen, with 18 quarter-gunnery, 1 carpenter's mate, with 8 assistants, and 1 steward and steward's mate under the purser.

Fourth Rates, consist of ships from 50 to 60 guns upon two decks and the quarter-deck. The lower tier is composed of 24 pounders, and the upper tier of 12 ditto, and the quarter deck and fore-castle 6 ditto. The complement of a 50-gun ship is 350 men in which there are 3 lieutenants, 2 master's-mates, 10 midshipmen, 2 surgeon's-mates, 6 quarter-masters and their mates, 4 boatswain's mates and yeomen, 1 gunner, and 1 yeoman, with 12 quarter-gunnery, 1 carpenter's mate, and 6 assistants, and a steward and steward's mate.

All vessels of war under the fourth rate are usually comprehended under the general names of frigates, and never appear in the line of battle. They are divided into two rates, viz.

Fifth Rates, mounting from 32 to 40 or 44 guns. The latter have two decks of cannon, the lower battery being of 18 pounders, and that of the upper deck 6 ditto; but those of 36, or 32 guns, have only one complete deck of guns, mounting 12 pounders, besides the quarter-deck and fore-castle, which carry 6 ditto. The complement of 44 guns is 280 men, and that of a frigate of 36 guns 240 men. The first has 3, and the second 2 lieutenants, and both have 2 master's-mates, 6 midshipmen, 2 surgeon's mates, 6 quarter-masters and their mates, 2 boatswain's-mates and 1 yeoman, 1 gunner's-mate and 1 yeoman, with 10 or 11 quarter-gunnery, and 1 purser's steward.

Sixth Rates, consist of frigates from 20 to 30 guns, and carry 9 pounders; those of 28 guns having 3 pounders on their quarter deck, with 200 men for their complement; and those of 24, 160 men. The former has 2 lieutenants, the latter 1, and both have two master's-mates, 4 midshipmen, 1 surgeon's-mate, 4 quarter-masters and their mates, 1 boatswain's mate and 1 yeoman, 1 gunner's mate and 1 yeoman, with 6 or 7 quarter-gunnery, and 1 purser's-steward. The whole of these

rates are termed post ships, i. e. their commander is a post captain, while those captains commanding vessels are denominated **MASTERS** and **COMMANDERS**; which see. This last rate is generally said to comprehend all brigs, sloops of war, cutters, schooners, &c. carrying from 6 to 18 guns, but it is only true with respect to their pay, the rest of their establishment of officers and crew varying according to their force and magnitude, many of them being commanded by lieutenants, and some, such as gun-boats, &c. by midshipmen, who have passed for lieutenants. The sloops of war carry from 6 to 10 cannon, the latter having 6 pounders, and the former (those from 8 to 10 guns) 4 pounders. Their officers are generally the same as in the sixth rates, with little variation, and their complement of men are from 120 to 60, in proportion to their force or magnitude.—N. B. Bomb-vessels are on the same establishment as sloops; but fire-ships and hospital-ships are on that of 6th rates.

RATEEN, in Commerce, a thick woollen stuff, quilted, worn on a loom with four treadles, like serge, and other stuffs, that have the whale or quilting.

RATIO, is the relation of two quantities of the same kind with respect to quantity, and is by some authors divided into arithmetical and geometrical ratio; viz. arithmetical, when the term is used with respect to the difference of the two quantities; and geometrical, when it relates to the number of times in which the one of those quantities is contained in the other;

thus the ratio of 6 to 3 is $\frac{6}{3} = 2$. The leading term of the ratio

being called the *antecedent*, and the latter the *consequent*; also the quotient or division of the former by the latter, is called the *index* or *exponent* of the ratio. The equality of ratios constitute proportion. See **PROPORTION**.

RATIO, is also distinguished by some authors, (principally of the old school,) into a variety of denominations, many of which are totally useless; but which cannot, notwithstanding, be passed over in the present article.

Irrational RATIO, is, when one of the terms of the ratio, at least, is an irrational quantity; such is the ratio of $\sqrt{3}$ to 1.

Rational RATIO, is when there is no irrational quantity entered, or when the same irrational quantity enters into both terms, thus $\sqrt{6}$ to $\sqrt{24} = \sqrt{6}$ to $2\sqrt{6} = 1$ to 2.

RATIO of Equality, is when the terms expressing the ratio are equal, and therefore the exponent = 1.

RATIO of Greater Inequality, is when the antecedent exceeds the consequent; and *ratio of less inequality*, is when the latter exceeds the former.

For several other distinctions, as *Compound*, *Duplicate*, *Subduplicate*, *Triplicate*, *Subtriplicate*, &c. see the several articles.

Reduction of RATIOS, is the reducing them to less terms, the ratio of 36 to 24 = 6 to 4 = 3 to 2. Sometimes, however, when the terms of the ratio are very large it is difficult to reduce them in this manner, and then recourse must be had to the method of finding the greatest common measure or common divisor, which also fails if the two terms are prime to each other. In this case, though the exact ratio cannot be found in less terms, it is frequently desirable to find an approximate ratio expressed in less terms, and recourse must then be had to continued fractions, viz. convert the given ratio into a continued fraction, and thence find the series of converging fractions, each of which will be an approximate ratio of the proposed one, and so much the more accurate as it is farther advanced in the series. Let 1103 to 887 be a ratio, to which it is required to find an approximate ratio in less terms.

$$887)1103(1$$

$$\begin{array}{r} 216)887(4 \\ 23)216(9 \\ 9)23(2 \\ 5)9(1 \\ 4)5(1 \\ 1)4(4 \end{array}$$

Hence by the rule in continued fractions,

$$\text{quote. } 1 \frac{4}{5} \frac{9}{46} \frac{2}{97} \frac{1}{143} \frac{1}{240} \frac{4}{1103}$$

$$\text{app. ratios } 1' \frac{4}{5} \frac{37}{76} \frac{76}{115} \frac{193}{287} \frac{887}{1103}$$

Each of which fractions approximates nearer to the true ratio than any of those which precede it, and each nearer than any ratio that can be expressed in less terms.

RATIOCINATION, the act of reasoning.

RATION, in the Army, a portion of ammunition, bread, drink, and forage, distributed to each soldier in the army, for his daily subsistence, &c. The horse have rations of hay and oats when they cannot go out to forage. The rations of bread are regulated by weight. The ordinary ration of a foot soldier is a pound and a half of bread per day. The officers have several rations according to their quality and the number of attendants they are obliged to keep. When the ration is augmented on occasions of rejoicing, it is called a double ration.

In the navy the rations of every man are a pound of bread and meat per day, a pint of chocolate for breakfast, half a pint of rum, which is mixed with water before it is served out; together with salt, vinegar, and vegetables.

RATIONABLES EXPENSÆ, reasonable expenses, paid to members of parliament, and the proctors of the clergy in convocation, by the people, determined by the king, the prices of the necessary articles being taken into a due consideration.

RATIONABILI PARTE BONORUM, a writ which lies for the wife against the executors of her husband, if they refuse her the third part of her effects, all debts being paid.

RATIONAL FRACTIONS, is the term commonly used to express those fractions which may be decomposed into other fractions, the sum of which is equal to the given fraction; this cannot in all cases be effected, but where it can, such fractions are called rational fractions. In simple numerical fractions, the decomposition, when it can be effected, is drawn from the indeterminate analysis. Thus, let it be proposed to resolve

the fraction $\frac{19}{35}$ into two other fractions. Since $35 = 7 \cdot 5$, let

the two required fractions be $\frac{x}{7}$ and $\frac{y}{5}$; then their sum $\frac{5x+7y}{35}$

$= \frac{19}{35}$; whence $5x + 7y = 19$, which is an indeterminate equation of the first degree, and the solution of it gives $x = 1$ and $y = 2$; therefore $\frac{19}{35} = \frac{1}{7} + \frac{2}{5}$.

If the denominator is a prime number, the decomposition is impossible, as it is also in some other cases; but if x and y are prime factors of the denominator, and the numerator is greater than $x \cdot y - x - y$, then the decomposition is always possible.

If the denominator consists of three or more prime factors, then making it equal to $\frac{a}{x} + \frac{b}{y} + \frac{c}{z} + \&c.$ the decomposition

may still be effected by means of an indeterminate equation of the first degree. But the principal use of this decomposition is in the inverse method of fluxions, or the integral calculus, for which purpose they were first investigated by Leibnitz, and have been since much extended by the researches of Cotes, Euler, Simpson, Lagrange, &c.

RATIONAL Quantities, in Algebra, are those which are expressed without any radical signs, being equivalent to integers, or fractions, in arithmetic, which are called rational numbers, or quantities, in contradistinction to irrational or surd quantities. See **SURDS**.

RATIONAL Horizon. See **HORIZON**.

RATIONALE, a solution or account of the principles of some opinion, action, hypothesis, phenomenon, or the like.

RATLINES, small lines which traverse the shrouds of a ship horizontally at regular distances from the deck upwards, and forming a variety of ladders whereby to climb or to descend from any of the mast-heads.

To rattle down the Shrouds, is to fix the ratlines to them in order to prevent them from slipping down by the weight of the sailors; they are firmly attached by a knot called a clove hitch, to all the shrouds except the fore-most or aft-most.

RAURAVA, a Sanscrit word meaning dreadful, and a name of one of the Hindoo hells. They reckon twenty-one of these receptacles for sinners, of which the Naraka is the most dreadful.

RAVELIN, in Fortification, was anciently a flat bastion,

placed in the middle of a curtain; but now a detached work, composed only of two faces which make a salient angle, without any flanks, and raised before the curtain on the counterscarp of the place. A ravelin is a triangular work, resembling the point of a bastion with the flanks cut off.

RAVEN. See **CORVUS**.

RAVISHMENT, in Law, denotes an unlawful seducing either a woman or an heiress in ward, for which there is a remedy by a writ of ravishment, or action of trespass, in the same manner as the husband may have it on account of the abduction of his wife.

RAW, in Agriculture, denotes any sort of plant, substance, or material, which is green, unripe, or in an undigested condition. Hence, raw land, raw cream, raw hide, raw silk, &c.

RAY, in Optics, a beam of light propagated from a radiant point. If the ray comes direct from the radiant point to the eye, it is said to be *direct*; if it first strike upon any body, and is hence transmitted to the eye, it is said to be *reflected*, and the ray itself is called a *reflected ray*; and if the ray in its passage to the eye be bent or turned out of its direct course by passing through any medium, it is said to be *refracted*, and is thence called a *refracted ray*. When two or more rays proceed in directions parallel to each other, they are called *parallel rays*. If they converge towards each other, they are called *converging rays*, and if they diverge, *diverging rays*; and those which pass directly to the eye in any case, are called *visual rays*. Among other qualities of rays it has been found, by experiment, that there is a very great difference in the heating power of the different rays from the sun.

It appears from the experiments of Dr Herschel, that the heating power increases from the middle of the spectrum to the red rays, and is greatest beyond it where the rays are invisible. Hence it is inferred, that the rays of light and caloric nearly accompany each other, and that the latter are in different proportions in the different coloured rays; these are easily separated from each other, as when the sun's rays are transmitted through a transparent body, the rays of light pass on seemingly undiminished, but the rays of caloric are intercepted. When the sun's rays are directed to an opaque body, the rays of light are reflected, and the rays of caloric are absorbed and retained. This is the case with the light of the moon, which, however much it be concentrated, gives no indication of being accompanied with heat. It has also been shewn, that the different rays of light produce different chemical effects on the metallic salts and oxides. These effects increase on the opposite direction of the spectrum, from the heating power of the rays. From the middle of the spectrum, towards the violet end, they become more powerful, and produce the greatest effect beyond the visible rays. From these discoveries it appears, that the solar rays are of three kinds. 1. Rays which produce heat. 2. Rays which produce colour; and 3. Rays which deprive metallic substances of their oxygen. The first set of rays is in greatest abundance, or are most powerful towards the red end of the spectrum, and are least refracted. The second set, or those which illuminate objects, are most powerful in the middle of the spectrum. And the third set produce the greatest effect towards the violet end, where the rays are most refracted. The solar rays pass through transparent bodies without increasing their temperature. The atmosphere, for instance, receives no increase of temperature, by transmitting the sun's rays, till these rays are reflected from other bodies or are communicated to it by bodies which have absorbed them. This is also proved by the sun's rays being transmitted through convex lenses, producing a higher degree of temperature when they are concentrated, but giving no increase of temperature to the glass itself. By this method, the heat which proceeds from the sun can be greatly increased. Indeed, the intensity of temperature produced in this way, is equal to that of the hottest furnace. This is done either by reflecting the sun's rays from a concave polished mirror, or by concentrating, or collecting them by the refractive power of convex lenses, and directing the rays thus concentrated on the combustible body. See **BURNING Glass**.

RAY, or **RYE GRASS**, in Agriculture, a valuable sort of early grass, that has been long, and still is much cultivated in some districts.

RAZOR, a well known keen edged instrument used in shaving. Heat appears to give a partial increase of tenacity to a razor's edge, but the reason has not been satisfactorily assigned.

REACH, in Sea Language, signifies the distance between any two points of land, lying nearly in a right line.

REACTION, in Physics, the action by which a body acted upon returns the action by a reciprocal one upon the agent.

REACTION, in Physiology, the resistance made by all bodies to the action or impulse of others, that endeavour to change their state whether of motion or rest.

REAGENT. In the experiments of chemical analysis, the component parts of bodies may either be ascertained in quantity as well as quality, by the perfect operations of the laboratory, or their quality alone may be detected by the operations of certain bodies called reagents. Thus the infusion of galls is a reagent, which detects iron by a dark purple precipitate; the prussiate of potash exhibits a blue, with the same metal, &c.

REALGAR, in Chemistry. Arsenic mineralized by sulphur forms two ores, named orpiment and realgar, the chemical distinction of which is not very accurately determined. That which has been named realgar is of a red colour, sometimes inclining to a scarlet, sometimes to orange. It occurs massive, disseminated, and crystallized, in oblique tetrahedral or hexahedral prisms, generally small and translucent, or semitransparent, with a shining lustre. Its fracture is uneven; it is soft and brittle, and has a specific gravity of 3.2, or 3.3. It exhales before the blow-pipe with a white arsenical and sulphurous odour, and gives a blue flame. It consists of arsenic and sulphur in the proportions of 80 of the former, and 20 of the latter.

REALISTS, a sect of school philosophers, who followed the doctrine of Aristotle with respect to universal ideas, in opposition to the *Nominalists*, who embraced the hypotheses of Zeno and the Stoics.

REAPING, in Agriculture, the operation of cutting crops either of corn, pease, beans, flax, &c. by means of a sickle or a reaping-hook. Several attempts have been made to construct reaping machines, but they have not hitherto been crowned with much success.

REAR, a name given to the last division of a squadron, or the last squadron of a fleet, and which is accordingly commanded by a third officer of the said squadron or fleet.

REASON, a faculty or power of the soul, by which it distinguishes good from evil, truth from falsehood; or, on comparing several things together, by which we draw consequences from the relations they are found to have. Mr. Locke observes, that reason comprehends two distinct faculties of the mind, namely, *sagacity*, by which it finds intermediate ideas, and *illation*, by which it so orders and arranges them, as to discover what connexion there is in each link of the chain by which the extremes are held together. By these means it draws into view the truth which was sought. All our ideas are either according to reason, above its comprehension, or contrary to its dictates. The first *must* be true, the second *may* be true, but the third *cannot*, and on this account should be rejected. Reason, as contradistinguished from faith, is the discovery of the certainty or probability of such propositions as it has obtained by the use of its natural faculties. Faith, on the other hand, is the assent of the mind to any given proposition upon the credit of the proposer. Thus Revelation is received as coming immediately from God.

REASONING, the exercise of the faculty of the mind called reasoning; or it is an act or operation of the mind, deducing some unknown proposition from other previous ones that are evident and known.

REAUMUR, RENE ANTOINE, a celebrated French philosopher, was born at Rochelle, in 1683. He was author of several works, but none that requires any mention in this article. He invented the thermometer which bears his name, a description of which is given under that article. Reaumur died in 1757.

REBATE, or **REBATEMENT**, in Commerce, a term much used at Amsterdam, for an abatement in the price of several commodities, when the buyer, instead of taking time, advances ready money.

REBELLION, taking up arms traitorously against the king, be it by natural subjects, or by others once subdued.

REBELLION, originally signified, among the Romans, a rising of such persons or tribes as had been formerly overcome in battle, and had yielded themselves to their subjection. It is now generally understood as a traitorous taking up arms against the king, either by his natural subjects, or by communities that had been subdued. Much, however, depends on the issue; a successful revolt makes a revolution, an unsuccessful one is rebellion.

REBUTTER, is the answer of the defendant to the plaintiff's sur-rejoinder.

RECAPITULATION, in Oratory, &c. is a summary, or a concise and transient enumeration of the principal thing insisted on in the preceding discourse, whereby the force of the whole is collected into one view.

RECAPTION. Where one has deprived another of his property, the owner may lawfully claim and retake it wherever he happens to find it, so that it shall not be in a riotous manner, or attended with any breach of the peace.

RECEIPTS, are acknowledgments in writing of having received a sum of money or other value. A receipt is either a voucher for an obligation discharged or one incurred. Receipts for money above 40s. must be on stamps; but on the back of a bill of exchange or promissory note which is already stamped is good without a further duty. Writing a receipt on a stamp of greater value than the law requires, incurs no penalty, and the receipt is good; but if on a stamp of a lower value, or on unstamped paper, then a receipt is no discharge, and incurs a penalty.

RECEIVER. Receivers are chemical vessels which are adapted to the necks or beaks of retorts, alembics, and other distillatory vessels, to collect, receive, and contain the products of distillations.

RECEIVER, in Pneumatics, a glass vessel for containing the thing on which any experiment in the air-pump is to be made.

RECESSION. See PRECESSION.

RECIPE, in Medicine, a prescription or remedy to be taken by a patient, so called because always beginning with the word recipe, i. e. take; which is generally denoted by the abbreviation R.

RECIPIANGLE, or **RECIPIENT ANGLE**, a mathematical instrument, serving to measure re-entering and salient angles especially in fortification.

RECIPROCAL, in Arithmetic and Algebra, is the quotient arising from dividing unity by any quantity; thus $1 \div x = \frac{y}{x}$ is the reciprocal of the fraction $\frac{x}{y}$.

RECIPROCAL Equations, are those which contain several pairs of roots, which are the reciprocal of each other.

RECIPROCAL Figures, in Geometry, are such as have the antecedent and consequents of the same ratio in both figures.

RECIPROCAL Proportion, is when the reciprocal of the two last terms have the same ratio as the quantities of the first terms, or when the antecedents are compared with the reciprocals of the consequents, thus, $5 : 8 :: 24 : 15$ is a reciprocal proportion, because $5 : 8 :: \frac{1}{8} : \frac{1}{5}$, or $5 : \frac{1}{8} :: 8 : \frac{1}{5}$.

RECIPROCAL Ratio, is the ratio of the reciprocals of two quantities.

RECIPROCAL Terms, among Logicians, are those which have the same signification; and consequently are convertible, or may be used for each other.

RECIPROCALLY, the property of being reciprocal; thus we say, that in bodies of the same weight, the density is reciprocally as the magnitude, viz. the greater the magnitude the less the density; and the less the magnitude, the greater the density. So again, the space being given, the velocity is reciprocally as the time.

RECIPROCITY. The law of reciprocity is a term employed by Legendre in his "Theory of Numbers," to denote a reciprocal law that has place between prime numbers of different forms, which is this, that m and n being prime odd numbers,

the remainder of $m^{\frac{n-1}{2}}$ divided by $n =$ the remainder of $1^{\frac{m-1}{2}}$ divided by m ; if m and n are not both of the form $4x - 1$, and

if they are both of this form, then the remainder of $m \frac{n-1}{2}$ divided by $n = -$ the remainder of $n \frac{n-1}{2}$ divided by m ; but with a contrary sign. See "Essai sur la Théorie des Nombres," p. 3.

RECITATIVO or **RECITATIVE**, in Music, a kind of singing that differs but little from ordinary pronunciation, such as that in which the several parts of the liturgy are rehearsed in cathedrals; or that in which the actors commonly deliver themselves on the theatre at the opera, when they are to express some action or passion, to relate some event, or reveal some design.

RECKONING, the art of estimating the quantity of a ship's way, or of the distance run between one place and another. Or more generally, a ship's reckoning is that account whereby at any time it may be known where the ship is, and on what course or courses she is to steer to gain her port. This is usually performed by means of the log-line. See **LOG-LINE**. Yet this is subject to great irregularities. Vitruvius advises an axis to be passed through the sides of the ship with two large heads propending out of the ship, wherein are to be included wheels touching the water, by whose revolution the space passed over in any given time may be measured. The same has been since recommended by Snelling, but there are few who have written on navigation but have shewn the insufficiency of this method.

RECLUSE, among religious, signifies a person shut up in a very narrow cell or hermitage, and secluded from all intercourse with the world and mankind.

RECLINER, in Dialling, is used for any dial whose plane reclines from the perpendicular; and if besides reclining, it also declines from any of the cardinal points, it is called a reclining declining dial, and the quantity or angle at which it declines or reclines, is called its reclination or declination.

RECOGNIZANCE, in Law, is an obligation of record which a man enters into before some court of record, or magistrate duly authorized, with condition to the same particular act, as to appear at the assizes or quarter sessions to keep the peace, &c. If the party does not comply with it, the recognizance is estreated into the exchequer. In some cases the court will upon motion respite, and in some discharge the recognizance; but all parties should be careful to apply in good time to the court where the recognizance is to be returned.

RECOIL, or **REBOUND**, the starting backward of a fire-arm, after an explosion. This term is particularly applicable to pieces of ordnance, which are always subject to a recoil, according to the sizes and the charges which they contain. To lessen the recoil of a gun, the platforms are generally made sloping towards the embrasures of the battery.

RECORD, an act committed to writing in any of the king's courts during the term wherein it is written, is alterable, being no record; but that term once ended, and the act duly enrolled, it is a record, and of that credit which admits of no alteration or proof to the contrary.

RECORDARI FACIAS, a writ directed to the sheriff, to remove a cause out of an inferior court, into the king's bench or common-pleas.

RECORDE, **ROBERT**, an eminent English mathematician, of the 16th century, author of several works on arithmetic, algebra, geometry, &c. and which were principally written in the form of dialogues between a master and his pupils.

RECORDER, a person whom the mayor and other magistrates of a city or corporation associate to them, for their better direction in matters of justice and proceedings in law; on which account, this person is generally a counsellor, or other person well skilled in the law.

RECOVERY, in Law, is obtaining any thing by judgment or trial at law. A recovery resembles a fine so far as being an action real or fictitious, and in that lands are recovered against the tenant of the freehold, and an absolute fee-simple is vested in the recovery; but it is carried on through every stage of proceeding, instead of being compromised like a fine.

RECTANGLE, in Geometry, the same with a right-angled parallelogram.

RECTANGULAR FIGURES and **SOLIDS**, are those which have one or more right angles. With regard to solids, they are commonly said to be rectangular when their axis are perpendicular to the planes of their bases.

RECTANGULAR Section of a *Cone*, was a term used by the ancients, before Apollonius, for the parabolic section.

RECTIFICATION, in Geometry, is the finding of a right line equal to a proposed curve; a problem that even in the present state of analysis is, in many cases, attended with some difficulty, and was in all totally beyond the reach of the ancient geometers, who were not able to assign the length of any curve line whatever, though they could, in a few cases, assign the area of a curvilinear space. It is to the doctrine of fluxions that we owe the complete rectification of curve lines, in finite terms, in all cases where they admit of it, and in others by means of infinite series, circular arcs, logarithms, &c.

RECTIFICATION, in Chemistry, the repetition of a distillation or sublimation several times, in order to render the substances purer, finer, and freer from aqueous or earthy parts.

RECTIFIER, an instrument used for determining the variation of the compass, in order to rectify the ship's course, &c. It consists of two circles, either laid upon or let into one another, and so fastened together in their centres, that they represent two compasses, the one fixed, the other moveable; each is divided into 32 points of the compass, and 360 degrees, and numbered both ways, from the north and the south, ending at the east and west, in ninety degrees. The fixed compass represents the horizon, in which the north and all the other points are liable to variation. In the centre of the moveable compass is fastened a silk thread, long enough to reach the outside of the fixed compass; but if the instrument be made of wood, an index is used instead of the thread.

RECTILINEAR, in Geometry, right-lined: thus figures whose perimeter consists of right lines are said to be rectilinear.

RECTORY, a parish, church, parsonage, or spiritual living, with all its rights, tithes, and glebes.

RECTUM, in Anatomy, is the last portion of the large intestine, and of the whole alimentary canal. This part of the human body is subject to disease, chiefly with those advanced in years, but young persons swallowing plum and cherry stones are not exempt.

RECURRING SERIES, is a series so constituted that each succeeding term is connected with a certain number of the terms immediately preceding it by a constant and invariable law; as the sums or differences of some multiples of those terms, &c.

RECURRING DECIMALS, those which are continually repeated in the same order, at certain intervals, as $\frac{1}{3} = .0666$, and $\frac{1}{7} = .272727$, &c.

RECUSANT, a person who refuses to go to church, and worship God after the manner of the church of England, as by law established; to which is annexed the penalty of 20l. a month for nonconformity. 24 Eliz. c. 1.

RECURVIROSTRA, the *Avoset* in Natural History, a genus of birds of the order grallæ. There are three species. The scooping avoset, found in this island, as large as the lapwing, has extremely long legs; its bill is three inches and a half in length. In winter it is often seen at the mouth of the Severn and on the coasts of Suffolk. In the fens of Cambridgeshire these birds are known to breed, and appear often in vast flocks. Their subsistence is on insects and worms, which they procure from the soft muddy bottoms with their bills. They often wade into the water to the top of their legs, and are able to swim; but are seldom seen swimming, and never, unless at a very small distance from the shore. In France, on the coasts of Bas Poitou, their nests are plundered annually of several thousands of eggs, which form a nourishing and valuable food for the peasantry of that district.

RED. See **COLOUR**.

RED, in Physics, or Optics, one of the simple or primary colours of natural bodies, or rather of the rays of light. The red rays are the least refrangible of all the rays of light. And hence, as Newton supposes, the different degrees of refrangibility to arise from the different magnitudes of the luminous particles of which the rays consist; therefore the red rays, or red light, is concluded to be that which consists of the largest particles. See **COLOUR** and **LIGHT**. Authors distinguish three general kinds of red, one bordering on the blue, as columbine, or dove colour, purple, and crimson; another bordering on yellow, as flame colour and orange; and between these extremes is a medium, which is that which is properly called red.

RED Clover, in Agriculture, an useful artificial grass fitted for arable lands. It has this name to distinguish it from white clover and some other sorts.

RED Shank, in Ornithology, a bird about the size of the common plover. On the back its colour is of a gray or brownish green, spotted with black; its breast white; wings and throat variegated. It breeds in fens and marshes, and during the winter season lies concealed in gutters. Its bill is about two inches long, and in shape resembles that of a woodcock.

RED Start, in Ornithology, is a beautiful bird, exquisite in plumage, moves its tail horizontally like a dog when fawning, has black legs, is remarkably shy, but has a soft and melodious note. It is migratory, and is found in this country only in spring and summer.

RED Wing, in Ornithology, a bird somewhat smaller than the thrush, and is less spotted. It is a bird of passage, coming on the approach of winter, supposed from the mountains of Germany and Bohemia.

RED Water, a disease in sheep, supposed to be caused by their taking too much watery food, such as turnips, clover, rape, &c. Its removal has been attempted by the use of common salt, a tea-spoonful of elixir of vitriol, and keeping the animals in action. A proportion of dry food is the best preventive.

RED Weed, is a name sometimes given to the round smooth-headed poppy, a pernicious weed in corn-fields.

RED Worm, the name of an insect very destructive to young corn-crops. Many experiments have been made on the best means of destroying it, but none have been found altogether effectual.

RED-BOOK, of the *Exchequer*, an ancient record or manuscript volume, in the keeping of the king's remembrancer, containing divers miscellaneous treatises relating to the times before the Conquest.

REDDENDUM, in our Law, is used substantively for the clause in a lease wherein the rent is reserved to the lessor.

REDDLE, **RED OCHRE**, or *Red Chalk*, in Mineralogy, the red oxide of iron united with earthy matter. It is used for crayons either in its natural state, or pulverized, washed, and afterwards mixed with gum, and cast into moulds.

REDEMPTION, in Law, a faculty or right of re-entering upon lands, &c. that have been sold and assigned, upon reimbursing the purchase-money with legal costs. Bargains wherein the faculty, or as some call it, the equity of redemption is reserved, are only a kind of pignorative contracts.

REDEMPTION, in Theology, denotes the recovery of mankind from sin and death, by the obedience and sacrifice of Christ, who is hence called the Redeemer of the world.

REDOUBT, or **REDOUTE**, in Fortification, a small square fort, without any defence but in front, used in trenches, lines of circumvallation, contravallation, and approach, as also for the lodgings of corps de garde, and to defend passages. In marshy grounds, redoubts are frequently made of stone-works for the security of the neighbourhood; their face consists of from 10 to 15 fathoms, the ditch round them from 8 to 9 feet broad and deep, and their parapets have the same thickness.

RED SNOW. The phenomenon of red snow, seen both on the coast of Baffin's bay and at Spitzbergen, has attracted much attention. This colouring matter has been found to have its origin from a very minute fungus which grows upon the snow, and which has been considered a species of *uredo*, and has been denominated *uredo nivalis*.

REDUCING SCALE, or *Surveying Scale*, is a broad thin slip of box, or ivory, having several lines and scales of equal parts upon it; used by surveyors for turning chains and links into rods and acres by inspection. It is used also to reduce maps and draughts from one dimension to another.

REDUCTION, in Arithmetic, is, by some authors on this subject, distinguished into reduction *ascending*, and reduction *descending*. The former, relating to the conversion of a quantity from a lower denomination to a higher; and the latter, when the quantity is to be reduced from a higher denomination to a lower.

REDUCTION, or **REVIVIFICATION**. This word, in its most extensive sense, is applicable to all operations by which any substance is restored to its natural state, or which is considered as such; but custom confines it to operations by which metals

are restored to their metallic state, after they have been deprived of this, either by combustion, as the metallic oxides, or by the union of some heterogeneous matters which disguise them, as fulminating gold, luna cornea, cinnabar, and other compounds of the same kind. These reductions are also called *revivifications*.

REDUNDANT HYPERBOLA, one of the higher order of hyperbolas, having more than two infinite branches.

REED, in Agriculture, the name of an aquatic plant infesting boggy low lands or meadows on the sides of rivers. Trunks, draining off the moisture by which it is supported, will destroy it. Ashes or soot has sometimes killed this weed.

REED, is also a term applied to such straw of wheat, oats, or rye, as has not been damaged by thrashing.

REED Hedge, in Gardening, is a hedge-fence which is formed of reeds. It is temporary and moveable, furnishing shelter to many seedlings and plants.

REEDS, in Fireships, are made up in small bundles of about twelve inches in circumference, cut even at both ends, and dipped in a kettle of melted composition, to render them easily ignitable.

REEF, a certain portion of a sail comprehended between the top or bottom and a row of eyelet holes generally parallel thereto. The intention of the reef is to reduce the surface of the sail in proportion to the increase of the wind, for which reason there are several reefs parallel to each other in the superior sails; thus the top sails of ships are generally furnished with three reefs, and sometimes four, and there are always three or four reefs parallel to the foot or bottom of these mainsails and fore-sails which are extended upon booms.

REEF, also implies a chain of rocks lying near the surface of the water.

REEF Band, a piece of canvass sewed across the sail to strengthen it in the place where the eyelet holes of the reefs are formed.

REEF-Line, a small rope, by which they formerly reefed the courses by passing it spirally through the holes of the reef, and over the head of the sail, alternately from the yard arms to the slings, and then straining it as tight as possible.

REEF-Tackle, a tackle upon deck, communicating with its pendant, which passing through a block at the top-mast-head, and through a hole in the top-sail yard-arm, is attached to a cringle a little below the lowest reef. Its use is to pull the skirts of the top-sails close up to the extremities of the top-sail yards, in order to lighten the labour of reefing.

Close-REEFED, is when all the reefs of the top-sails are taken in.

REEFING, the operation of reducing a sail by taking in one or more of the reefs, and is either performed with lines, points, or knittles. The top sails are always and the courses generally reefed with points, which are flat braided pieces of cordage, whose lengths are nearly double the circumference of the yard. These being inserted in the eyelet holes, are fixed in the sail by means of two knots in the middle, one of which is before and the other behind the reef-band.

In order to reef the top-sails with more facility and expedition, they are lowered down, and made to shiver in the wind; the extremities of the reef are then drawn up to the yard-arms by the reef-tackles, where they are securely fastened by the carings; the space of sail comprehended in the reef is then laid smoothly over the yard in several folds, and the whole is completed by tying the points about the yard so as to bind the reef up close to it. In reefing a course, the after end of the point should be thrust forward between the head of the sail and the yard, and the fore leg of the same point should come aft over the head of the sail, and also under the yard, and thus crossed over the head of the sail, the two ends should be tied on the upper side of the yard as tight as possible. When a sail is reefed at the bottom, it is generally done with knittles in the room of points, or in large sails, such as the main sails of armed cutters, pieces of lime, termed reef-lanks, are fixed in the eyelet-holes.

REEL, in the manufactories, a machine serving for the office of reeling. There are various kinds of reels, some very simple, others very complex. Of the former kinds those most in use are, 1. A little reel held in the hand, consisting of three pieces of wood, the biggest and longest whereof, (which does

not exceed a foot and a half in length, and one-fourth of an inch in diameter) is traversed by two other pieces disposed different ways. 2. The common reel or windlass, which turns upon a pivot, and has four flights traversed by long pins or sticks, whereon the skein to be reeled is put, and which are drawn closer or opened wider according to the skein.

REELING, in the Manufactories, the winding of thread, silk, cotton, or the like, into a skein.

REELS, are machines moving round an axis, and serving to wind various lines upon, as the

Deep-Sea-REEL, that which contains the deep-sea line;

Log-REEL, that appropriated for the log-line.

RECTIFICATION, in Chemistry, the repetition of a distillation or sublimation several times, in order to render the substances purer, finer, and freer from aqueous or earthy parts.

REEM. See RHINOCEROS.

REEMING, a term used by caulkers for opening the seams of the planks with irons, for the more easy admission of oakum. In common language, to make any hole larger, is in many places termed reeming.

RE-ENTRY, in Law signifies the resuming or retaking the possession of lands lately lost.

REEVING, in the Sea Language, the putting a rope through a block; hence to pull a rope out of a block is called unreeving.

REFERENCE, in Law, is where a matter is referred by the court of chancery to a master, and by the courts at law to a prothonotary, or secondary, to examine and report to the court. Reference also signifies where a matter in dispute is referred to the decision of an arbitrator. This is done either by parol, agreement, or by bond, or upon a suit, in which latter case the party has a rule of court, that the party against whom the award is made shall perform it, and then he may move to have an attachment against him, if he does not perform it. By statute also this may be done, where the parties agree that the award should be made a rule of court, although there is no suit.

REFINING, in general, is the art of purifying a thing; including not only the assaying or refining of metals, but likewise the depuration or clarification of liquors. Gold and silver may be refined by several methods, which are all founded on the essential properties of the metals, and acquire different names according to their kinds.

REFINING, in Metallurgy, is the means of obtaining metals from their ores, and freeing them from all other impurities, whether natural or artificial. The term is applicable to the purification of things in general.

REFITTING, in sea language, is generally understood to imply the repairing any damages which a ship may have sustained in her sails or rigging by battle or tempest, but more particularly by the former.

REFLECTION, or **REFLEXION**, in Mechanics, is the return or regressive motion of a moveable body, arising from the reaction of some other body on which it impinges. The reflection of bodies after impact is attributable to their elasticity, and the more perfectly they possess this property, the greater will be their reflection, all other things being the same. In case of perfect elasticity, they would be reflected back again with the same velocity, and at an equal angle with which they met the plane; that is, the angle of incidence would be equal to the angle of reflection, and the velocity both before and after impact would be the same, at equal distance from the body on which they impinge.

REFLECTION of the Rays of Light, in Catoptrics, is their return, after their approaching so near the surfaces of bodies as to be repelled or driven backwards. See OPTICS.

REFLECTION of Heat. In the same manner as we find the rays of light are reflected by polished surfaces, so it is found that the rays of caloric have precisely the same property. The Swedish chemist, Scheele, discovered, that the angle of reflection of the rays of caloric is equal to the angle of incidence, a fact which has been more fully established by Dr. Herschel. Some very interesting experiments were made by Professor Plözet, of Geneva, which proved the same thing. These experiments were conducted in the following manner:—Two concave mirrors of tin, of nine inches focus, were placed at the distance of twelve feet two inches from each other; in the focus

of the one was placed the bulb of a thermometer, and in that of the other a ball of iron two inches in diameter, which was just heated so as not to be visible in the dark. In the space of six minutes the thermometer rose 22°. A similar effect was produced by substituting a lighted candle in place of the ball of iron. Supposing that both the light and heat might act in the last experiment, he interposed between the two mirrors a plate of glass, with the view of separating the rays of light from those of caloric. The rays of caloric were thus interrupted by the plate of glass, but the rays of light were not perceptibly diminished. In nine minutes the thermometer sunk 14°; and in seven minutes after the glass was removed, it rose about 12°. He therefore justly concluded, that the caloric reflected by the mirror was the cause of the rise of the thermometer. He made another experiment, substituting boiling water in a glass vessel in place of the iron ball; and when the apparatus was adjusted, and a screen of silk, which had been placed between the two mirrors, removed, the thermometer rose 3°; namely, from 47° to 50°. The experiments were varied by removing the tin mirrors to the distance of 90 inches from each other. The glass vessel, with boiling water, was placed in one focus, and a sensible thermometer in the other. In the middle space between the mirrors, there was suspended a common glass mirror, so that either side could be turned towards the glass vessel. When the polished side of this mirror was turned towards the glass vessel, the thermometer rose only five-tenths of a degree; but when the other side, which was darkened, was turned towards the glass vessel, the thermometer rose 3° 5'. And in another experiment, performed in the same way, the thermometer rose 3° when the polished side of the mirror was turned to the glass vessel, and 9° when the other side was turned, which experiments shew clearly, that the rays of caloric are reflected from polished surfaces, as well as the rays of light. Transparent bodies have the power of refracting the rays of caloric as well as those of light. They differ also in their refrangibility. So far as experiment goes, the most of the rays of caloric are less refrangible than the red rays of light. The experiments of Dr. Herschel shew that the rays of caloric, from hot or burning bodies, as hot iron, hot water, fires, and candles, are refrangible, as well as the rays of caloric which are emitted by the sun. Whether all transparent bodies have their power of transmitting these rays, or what is the difference in the refractive power of these bodies, is not yet known.

The light which proceeds from the sun seems to be composed of three distinct substances. Scheele discovered that a glass mirror, held before the fire, reflected the rays of light, but not the rays of caloric; but when a metallic mirror was placed in the same situation, both heat and light were reflected. The mirror of glass became hot in a short time, but no change of temperature took place on the metallic mirror. This experiment shews that the glass mirror absorbed the rays of caloric, and reflected those of light; while the metallic mirror, suffering no change of temperature, reflected both. And if a plate of glass be held before a burning body, the rays of light are not sensibly interrupted, but the rays of caloric are intercepted; for no sensible heat is observed on the opposite side of the glass; but when the glass has reached a proper degree of temperature, the rays of caloric are transmitted with the same facility as those of light. And thus the rays of light and caloric may be separated; and the curious experiments of Dr. Herschel have clearly proved, that the invisible rays which are emitted by the sun have the greatest heating power. In these experiments, the different coloured rays were thrown on the bulb of a very delicate thermometer, and their heating power was observed. That of the violet, green, and red rays, were found to be to each other as the following numbers:—

Violet, 16 0 : : : : Green, 22 4 : : : : Red, 55 0.

The heating power of the most refrangible rays was least, and this increases as the refrangibility diminishes. The red ray, therefore, has the greatest heating power, and the violet, which is the most refrangible, the least. The illuminating power, it has been already observed, is greatest in the middle of the spectrum, and diminishes towards both extremities; but the heating power, which is least at the violet end, increases from that to the red extremity, and when the thermometer was placed beyond the limit of the red ray, it rose still higher than in the

red ray, which has the greatest heating power in the spectrum. The heating power of these invisible rays was the greatest at the distance of half an inch beyond the red ray, but it was sensible at the distance of one inch and a half.

REFLECTING CIRCLE, an astronomical instrument for measuring angles. It is called reflecting from its property, in common with the Hadley's quadrant, (of which it is a modification) of observing one of the objects of the angle to be measured by distinct vision, and the other by reflection of plane mirrors.

REFLECTOIRE CURVE, is a term given by Mairan to the curvilinear appearance of the plane surface of a basin containing water to an eye placed perpendicularly over it. In this position the bottom of a basin will appear to rise upwards from the centre outwards, but the curvature will be less and less, and at last the surface of the water will be an asymptote to it.

REFLECTOR, a mirror or looking-glass.

REFLEXIBILITY, the property necessary for reflection.

REFLUX of the SEA. See **TIDE**.

REFORM, a revival of former discipline, a re-establishment of partially neglected or abandoned principles, or a correction of some reigning abuses in them.

REFORMATION, the act of correcting abuses. More emphatically, the term is applied to the throwing off the papal yoke, about the beginning of the sixteenth century. To this noble act we are indebted for the religious privileges we enjoy, and many of our civil blessings may be traced to the same source.

REFRACTED ANGLE, or *Angle of Refraction*, is the angle which a refracted ray makes with the surface of the refracting body. The complement of this angle is, however, sometimes called the refracted angle.

REFRACTION of the rays of light. See **OPTICS**.

REFRACTION, in Astronomy, is an inflection of the rays of light proceeding from the heavenly bodies, in passing through the atmosphere by which their apparent altitudes are increased.

Atmospherical REFRACTION. It is evident, from the nature and progression of light, that rays, in passing from any object through the atmosphere, or part of it, to the eye, do not proceed in a right line; but the atmosphere being composed of an infinitude of strata, (if we may so call them,) whose density increases as they are posited nearer the earth, the luminous rays which pass through it are acted on as if they passed successively through media of increasing density, and are, therefore, inflected more and more towards the earth as the density augments. In consequence of this it is, that rays from objects, whether celestial or terrestrial, proceed in curves which are concave towards the earth: and thus it happens, since the eye always refers the place of objects to the direction in which the rays reach the eye, that is, to the direction of the tangent to the curve at that point, that the apparent or observed elevations of objects are always greater than the true ones. The difference of these elevations, which is in fact the effect of refraction, is, for the sake of brevity, called refraction; and it is distinguished into two kinds, horizontal, or terrestrial, refraction, being that which effects the altitude of hills, towers, and other objects on the earth's surface; and astronomical refraction, or that which is observed with regard to the altitudes of heavenly bodies. Refraction is found to vary with the state of the atmosphere in regard to heat or cold, and humidity, so that determinations obtained for one state of the atmosphere, will not answer correctly for another without modification. Tables commonly exhibit the refraction at different altitudes, for some assumed mean state.

REFRACTION of Altitude, is an arc of a vertical circle, by which the altitude of a star is increased by the refraction.

REFRACTION of Ascension or Descension, is an arc of the equator by which the ascension or descension, whether right or oblique, is increased or diminished by refraction.

REFRACTION of Declination, is the increase or decrease in the declination of a star by refraction.

REFRACTION, in Latitude, is the increase or decrease of the latitude of a star from refraction.

REFRACTION, in Longitude, is the increase or decrease in the longitude of a star from refraction.

REFRACTION, in Mechanics, is the deviation of a body in motion, from its direct course, in consequence of the variable

density of the mediums in which it moves. This, however, except in speaking of the rays of light, is commonly called *deflection*.

REFRACTION, in Iceland crystal. There is a double refraction in this substance, contrary ways, by which not only oblique rays are divided into two, and refracted into opposite parts, but even perpendicular rays are one half refracted.

REFRANGIBILITY of LIGHT, the property of the rays to be refracted, but more commonly employed with reference to the different degrees in which the different rays possess this property; and on which Newton has founded his whole theory of colours. For the several experiments relating to this subject, see **PRISM**.

REFRIGERATION, the act of cooling, or the abstracting of heat from various substances, for the purpose of art or domestic use.

REFUGE, in antiquated customs, a sanctuary or asylum. In the Old Testament, six cities of refuge were appointed for the protection of persons from the rigour of the law, who were guilty of involuntary homicide.

REFUGEES, French Protestants who, on the revocation of the edict of Nantz in 1685, fled from persecution, and found shelter in Holland, Germany, and England, where they carried many valuable arts, by which these countries have been enriched and France has been impoverished.

REGAL, something belonging to a king. Regal is also a musical term, and likewise a species of portable organ much used in processions in papal countries.

REGALE, in French jurisprudence, is a right belonging to the king over all benefices in that kingdom. It consists in the enjoyment of the revenues of bishops' sees during their vacancy, and in the presentment to benefices dependent on them.

REGALIA, in Law, the rights and prerogatives of a king, which, according to the civilians, are six, viz. 1. The power of judicature; 2. the power of life and death; 3. the power of peace and war; 4. a right to such goods as have no owner, as waifs, estrays, &c. 5. assessments; and 6. the coinage of money. Regalia is also used for the apparatus of a coronation, as the crown, the sceptre with the cross, and with the dove, St Edward's staff, the globe, and the orb with the cross, four several swords, &c.

REGARDANT, in Heraldry, is understood of a lion or other beast of prey, in the attitude of looking behind him with his eyes towards his tail.

REGARDANT Villain, an ancient servant or retainer to the lord, because charged with the base services within the manor, to see that all filth and nuisances are removed.

REGARDER of the FOREST, an ancient officer, whose business it was every year to make oath to the limits of the forest, and also to inquire into all offences committed within its jurisdiction.

REGATTA, a name given in Venice to exhibitions on the water, such as a contest for superiority in rowing and the management of boats.

REGEL, or **RIGEL**, a fixed star of the first magnitude, in the left foot of Orion.

REGENERATION, in Theology, the act of being born again by a spiritual birth, or becoming a child of God, through which the person abandons a course of vice, and leads a life of piety and virtue.

REGENT, one who governs a kingdom during the minority or absence of the king. In France the queen mother has the regency of the kingdom during the minority of the king, under the title of the queen regent. Regent also signifies a professor of arts and sciences in a college, who has a set of pupils under his care; but here regent is generally restrained to the lower classes, as regent of rhetoric, regent of logic, &c. those of philosophy are rather called professors. The foreign universities are generally composed of doctors, professors, and regents.

REGERENDARIUS, among the Romans, was an officer who subscribed and kept a register of all petitions presented to the prefect.

REGICIDE, a king-killer. The term is also used for the act of murdering the king. It is now generally applied to those persons who were engaged in the trial, condemnation, and execution of Charles I.

REGIMEN, the regulation of diet, and, in a more general sense, of all the nonnaturals, with a view to preserve or restore health.

REGIMEN, in Grammar, that part of syntax or construction which regulates the dependency of words, and the alteration which one occasions in another.

REGIMENT, in War, is a body of men, either horse or foot, commanded by a colonel. Each regiment of foot is divided into companies, but the number of companies is not always alike, though our regiments generally consist of ten companies, one on the right, of grenadiers, and another on the left, of light troops. Regiments of horse most commonly consist of six troops, but some have nine. Regiments of dragoons, in time of war, are generally composed of eight troops, and in time of peace of six.

REGINA AURARUM, in Ornithology, a large Mexican bird about the size of an eagle. Its whole body is covered with a plumage of a blackish purple. Its feet are red, its beak like that of a parrot; it feeds on rats, mice, snakes, and other vermin, and can fly against the fiercest wind.

REGION, in Physiology, particular districts on the surface of the globe, disposition of internal strata, and distinguished elevations in the atmosphere, and depths in the sea.

REGION, in Anatomy, denotes the division of the human body.

REGIONARY, in Ecclesiastical History, a title given in the 8th century to persons who had the charge and administration of church affairs within a certain district or region.

REGIS, PETER SYLVAIN, a French philosopher, was born in 1632, author of a "System of Philosophy," in 3 vols. 4to. published in 1690, and some other works. He died in 1707, at 75 years of age.

REGISTER, a public book, in which is entered and recorded memoirs, acts, and minutes, to be had recourse to occasionally, for knowing and proving matters of fact. Of these there are several kinds: as, 1. Registers of deeds in Yorkshire and Middlesex, in which are registered all deeds, conveyances, wills, &c. that affect any lands or tenements in those counties, which are otherwise void against any subsequent purchasers or mortgagees, &c. but this does not extend to any copyhold estate, nor to leases at a rack-rent, or where they do not exceed 21 years. The registered memorials must be engrossed on parchment, under the hand and seal of some of the grantors or grantees, attested by witnesses who are to prove the signing or sealing of them, and the execution of the deed. But these registers, which are confined to two counties, are in Scotland general, by which the laws of north Britain are rendered very easy and regular. Of these there are two kinds; the one general, fixed at Edinburgh, under the direction of the Lord Register; and the other is kept in the several shires, stewartries, and regalties, the clerks of which are obliged to transmit the registers of their respective courts to the general register. No man in Scotland can have a right to any estate, but it must become registered within forty days of his becoming seised thereof; by which means all secret conveyances are cut off. 2. Parish registers are books in which are registered the baptism, marriages, and burials, of each parish.

REGISTER, is also used for the clerk or keeper of a register. Of these we have several, denominated from the registers they keep: as, register of the high court of delegates; register of the arches court of Canterbury; register of the court of admiralty; register of the prerogative court; register of the garter, &c.

REGISTER, in Printing, is disposing the forms on the press, so that the lines and pages printed on one side of the sheet fall exactly on those of the other.

REGISTER, among letter-founders, is one of the inner parts of the mould in which the printing types are cast. Its use is to direct the joining of the mould justly together again, after opening it to take out the new-cast letter.

REGIUS PROFESSORS. Henry VIII. founded five lectures in each of our universities, viz. Divinity, Hebrew, Greek, Law, and Physic, the readers of which lectures are in the universities' statutes called *regii professores*.

REGLE, in Music, a rule for accompanying the octave ascending and descending in the base, giving to each note of the scale its appropriate harmony in every key.

REGLETS, or **RIGLETS**, in Printing, are thin slips of wood 90.

exactly planed to the size of the body of the letter. The smaller sorts are placed between the lines of poetry, and both those and larger are used in filling up short pages, in forming the whites or distances between the lines of titles, and in adjusting the distances of the pages in the chase, so as to form register.

REGRATOR, or **REGRATER**, in Law, formerly signified one who bought wholesale, or by the great, and sold again by retail; but the term is now used for one who buys any wares or victuals, and sells them again in the same market or fair, or within five miles round it.

REGRATOR, is also used for one who furbishes up old moveables to make them pass for new. And masons who take off the outside surface of hewn stone, in order to whiten it, or make it look fresh again, are said to regrate.

REGRESSION. See **RETROGRESSION**.

REGULAR, denotes any thing that is agreeable to the rules of art; thus we say a regular building, verb, &c. A regular figure in Geometry is one whose sides, and consequently angles, are equal; and a regular figure with three or four sides, is commonly termed an equilateral triangle or square, as all others with sides are called regular polygons. All regular figures may be inscribed in a circle. A regular solid, called also a platonic body, is that terminated on all sides by regular and equal planes, and whose solid angles are all equal.

REGULAR Bodies, are those which have all their sides, angles, and faces, similar and equal. Of these there are only five, viz.

the *Tetraedron*, contained by four equilateral triangles;

the *Hexaedron*, or *cube*, by six squares;

the *Octaedron*, by eight triangles;

the *Dodecaedron*, by twelve pentagons; and

the *Icosaedron*, by twenty triangles.

For the properties of which see the several articles; see also Hutton's "Mensuration," sect. 2.

REGULATING CAPTAIN, an officer whose duty it is to examine the seamen intended for the navy, whether pressed or volunteers.

REGULATOR of a **WATCH**, the small spring belonging to the balance, serving to adjust its motions, and make it go faster or slower.

REGULATOR of **Velocity**, in Mechanics, is a contrivance for regulating or governing the motions of a mill, or other machinery, causing the motion of its parts to preserve an equable velocity, under all the variations of the propelling cause.

REGULUS. The name *regulus* was given by chemists to metallic matters when separated from other substances by fusion.

REGULUS, a fixed star of the first magnitude in the constellation Leo; sometimes called *Cor Leonis*, or Lion's Heart. By the Arabians it was termed *Alhabor*, and by the Chaldeans *Kalbeleceid*.

REHEARING, in the Court of Chancery, is a process to which either party, who thinks himself aggrieved, may have recourse, before the execution of a final decree.

REHEARSAL, in Music and the Drama, is an experiment on some composition in private, that the actors may better understand their parts.

REIGNING WINDS, a name given to the winds which usually prevail on any particular coast or region. See **WIND**.

REIMBURSEMENT, in Commerce, the act of repaying what monies had been received by way of advance. A person who gives a bill of exchange in payment, is to reimburse it, if protested, or not paid.

REIN DEER, in Zoölogy. This species of the deer kind is generally described as having horns ramosc, recurvated round with palmated summits. When full-grown, this animal, according to Pennant, is four feet six inches high, the body of a somewhat thick and square form, and the legs shorter than those of the common stag. The general colour is brown above and white beneath, but advancing in age it frequently becomes of a greyish white, and sometimes almost black. Both sexes are furnished with horns; those of the male are much larger and longer than those of the female. To the Laplander this animal is considered as the common substitute of the horse, the cow, the sheep, and the goat. The milk furnishes cheese, the flesh fowl, the skin clothing, the tendons bow-strings, and, when split, thread, the horns glue, and the bones spoons. A Laplander

is sometimes possessed of a thousand deer. Their chief food is a species of moss, which covers vast tracts of the northern regions. This they find in abundance during the summer, but in winter their fodder is scarce, and then the greatest care and attention are required for their support. Trained when young to draw the sledge, their services are of the utmost importance when grown to maturity. They will then proceed about thirty miles per day without sustaining any injury, and sometimes, when pressed, from fifty to sixty; but such journeys generally prove fatal to the animal. The rein deer is a native of the northern regions. In Europe its chief residence is Norway and Lapland. In Asia, Siberia and Kamtschatka. In America, Greenland and the neighbourhood of Hudson's Bay, but it is rarely found to the south of Canada. A few years since an attempt was made to introduce the breed into this country, but success did not equal expectation. The common deer are more preserved in England than in any other country. They are said to have been first introduced into Scotland from Norway by James I. and from thence into South Britain. They now abound in almost every county. Of these animals, under the generic term *Cervus*, there are many species, differing from each other in habit and appearance, the particulars of which may be found in works on natural history.

REINHOLD, ERASMUS, an eminent German mathematician and astronomer, was born in Upper Saxony in 1511, and died in 1553, in his 42nd year. Reinhold was author of several works, of which only the four following were published, viz. 1. *Theoria novæ Planetarum G. Purbachii*, 8vo. 1542, and again in 1580. 2. *Ptolemy's Almagest*, the first book in Greek, with a Latin version and Scholia, 8vo. 1549. 3. *Prutenicæ Tabula Coelestium Mutuum*, 4to. 1551; 2nd edition in 1571; 3d, 1585. 4. *Primus Liber Tabularum Directionum*, or Tables of Tangents to every minute of the quadrant. And new Tables of Climates, Parallels, and Shadows, with an Appendix, containing the second book of the Canon of Directions, in 4to. 1554. Besides these works, Reinhold was author of several others, which were never published.

REINS, in Anatomy, the kidneys: in Horsemanship, long leathers fastened to the bit of the bridle, by which the horse is kept in subjection.

REINSURANCE, in Commerce, a contract by which the first insurer relieves himself from the risks he had undertaken, and devolves them upon other underwriters, called re-insurers.

REITERATION, the art of repeating a thing, or doing it a second time.

REJOINDER, in Law, is the defendant's answer to the plaintiff's replication or reply.

REJOINTING, in Architecture, the filling up of joints of the stone in old buildings, when worn by time, and the action of the elements.

RELAPSE, in Medicine, the return of a disease when its virulence appeared to have been subdued, and the patient was regaining health.

RELATION, in Philosophy, the mutual respect of two things, or what each is in regard to the other. Hence, relation may be moral, physical, or ideal; but some comparison or affinity is always implied in that which has only a relative existence.

RELATION, in Kindred, denotes degrees of consanguinity. In Grammar, relation is the correspondence which words have with one another in construction. In Logic, it is an accident of substance, accounted one of the ten categories, or predicaments.

RELATION, in Mathematics, is the same as **RATIO**, though we sometimes use it in a more general sense, indicating any dependence of one quantity upon another.

RELAXATION, in Law. See **RELEASE**.

RELAY, a fresh equipage, horse, &c. sent before, or appointed to be ready for a traveller on his arrival, to make the greater expedition in his journey.

RELEASE, in Law, is an instrument in writing, by which estates, rights, titles, entries, actions, and other things, are extinguished and discharged; and sometimes transferred, abridged, or enlarged: and in general, it is to signify a person's giving up or discharging the right or action he has, or claims to have, against another, or his lands, &c. A release may be either in fact or in law: a release in fact is where it is expressly declared

by the very words, as the act and deed of the party; and a release in law, is that which acquits by way of consequence, as where a female creditor takes the debtor to be her husband.

RELEGATION, a kind of exile or banishment, by which an obnoxious person is commanded to retire to a certain place prescribed, and to remain until recalled or removed.

RELICS, in the Romish church, are the remains of some body, clothes, or furniture, said to have belonged to a saint or martyr, devoutly preserved in honour of his memory, and carried in procession, kissed, and venerated. To these relics superstition has attached miraculous powers, and in this mummery that church has carried on a profitable trade for many centuries.

RELICT, in Law. See **WIDOW**.

RELIEF, in Law, a certain sum of money which the tenant holding by knight's service, grand serjeantry, or other tenure, and being at full age at the death of his ancestor, paid to his lord at his entrance.

RELIEVE, in Military language, is to take the place of another.

RELIEVE, in Chancery, denotes an order sued out for the dissolving of contracts, and other acts done, on account of their being unreasonable, prejudicial, or grievous.

RELIEVING TACKLES, two strong tackles, furnished each with guys and pendants, which, passing under the ship's bottom to the opposite side, are attached to the lower gun-ports; the tackles being hooked to the wharf or pontoon, by which the vessel is careened. They are used to prevent a ship from overturning on the careen, and to assist in bringing her upright after that operation is finished. *Relieving Tackles*, are also those which are occasionally hooked to the tiller in bad weather or in action, when the wheel or tiller-rope is broken or shot away. *Relieving Tackle*, is also a name sometimes given to the train-tackle of a gun carriage.

RELIEVO, or **RELIEF**, are terms applied to that mode of working in sculpture by which figures are made to project from the ground or body on which they are formed, and to which they remain attached. The same term is used, whether the figure is cut with the chisel, modelled in clay, or cut in metal or plaister. There are three kinds of relievo: *Alto-relievo*, or high relief, when the figures are so prominent from the ground that merely a small part of them remains attached to it. *Mezzo-relievo*, or half relief, when one half of the figure rises from the ground, in such a manner that the figure appears divided by it. *Basso-relievo*, or bas-relief (low relief), when the work is raised but little from the ground, as in medals, and generally in friezes and other ornamented parts of buildings. *Bas-relief* is the comprehensive term by which all works in relieve are denominated indiscriminately. See **SCULPTURE**.

RELIGION, is that worship or homage which is due to God considered as Creator and Preserver, and, with Christians, as Redeemer of the world. The foundation of all religion is, that there is a God, and that for his infinite perfections and innumerable favours he requires some acknowledgment and service from his creatures. Hence religion necessarily supposes some intercourse between God and Man. Religion has been divided into two branches, natural and revealed. The existence of the former has been disputed, and the latter has been subject to an endless diversity of interpretations. The thirty-nine articles of the established church of England are presumed to include the essentials of Christianity, and seditious words spoken in derogation of its truth are indictable as tending to a breach of the peace. 1 Haw. 7.

RELIQUA, in Natural History, a term used to express the fossil remains of various animal, vegetable, and other substances, found in a state of petrification, in different parts of the earth. Mr. Martin divides them into five classes, namely, fossil remains of animals or plants, earths, salts, inflammable substances, and metallic substances. Of these, the history is both curious and interesting.

RELIQUÆ, in Antiquity, the ashes and bones of the dead, which remain after the body had been burnt. These were carefully gathered up, and put into urns, and afterwards deposited in tombs.

RELIQUARY, a shrine or casket in which the relics of saints are kept.

RELL, the English name of the white-bellied mouse, with a blackish back and a long tail.

REMAINDER, that which arises by subtracting one quantity from another.

REMAINDER, in Law, is an estate limited in lands, tenements, or rents, to be enjoyed after the expiration of another particular estate. As if a man seised in fee-simple grant lands to one for twenty years, and, after the determination of the said term, then to another, and his heirs for ever; here the former is tenant in years, remainder to the latter in fee. Both interests are, in fact, only one estate; the present term of years, and the remainder afterwards, when added together, being equal only to one estate in fee. When the remainder is limited in a will, it is sometimes called an executory devise. This is not strictly a remainder, but something in nature of a remainder, which, though informal and bad, as such, is held good as an executory devise. The doctrine of remainders is very abstruse, chiefly from the difficulty of ascertaining from the form of the deed or will by which it is created, whether or not the remainder is contingent, and liable to be defeated. Where a remainder is limited after an estate tail, the tenant in tail can at all times, by suffering a recovery, defeat the remainder, and get possession of the fee. This is called *docking the entail*, and it is allowed for the purpose of preventing limitations in perpetuity. For, otherwise, men of large landed estates would be enabled to tie up the inheritance so strictly by will, that in a few years all the landed property in the kingdom would be vested for ever in certain families, and that circulation of wealth, which is the great spur to industry, would be wholly at an end.

REMANCIPATION was a form of divorce among the Romans, which was connected with some curious formalities.

REMEDY, in Law, is the action or means given by law for the recovery of any supposed right.

REMEDY, in Medicine, is any physical agent by which a disease may be alleviated or cured.

REMEMBRANCERS, anciently called clerks of the remembrance, certain officers in the exchequer, whereof three are distinguished by the names of the king's remembrancer, the lord treasurer's remembrancer, and remembrancer of the first fruits.

REMINISCENCE, is that power of the mind by which it recalls things which had been forgotten. In this respect it differs from memory with uninterrupted remembrance, while reminiscence allows intervals of forgetfulness. The ancient Platonists were of opinion, that all learning, knowledge, and invention, consisted in the recollection of notices which had been in the soul prior to its union with the body.

REMISSION, in Law, is the pardon of a crime. In Medicine, it is the abatement of a disorder, which returns again after an interval. In Physick, it is the diminution of the power or efficacy of any quality.

REMIT, in Commerce. To remit a sum of money, bill, or the like, is to send the sum of money, &c.

REMITTER, in Law, is where one that has a right to lands, but is out of possession, has afterwards the freehold cast upon him by some subsequent defective title, and enters by virtue of that title.

REMONSTRANCE, an expostulation, or humble supplication, presented to the king, or other superior, praying him to reflect on the inconveniences of specific edicts or measures. It also implies a gentle reproof, but touched in a delicate manner.

REMONSTRANTS, a title given to the Arminians, in consequence of their remonstrance in 1610, to the states of Holland, against the synod of Dort, in which their principles were condemned.

REMOVER, in Law, is where a suit is removed or taken out of one court into another; and is the opposite of remanding a cause, or sending it back into the same court whence it was first called.

RENCOUNTER, the encounter of two small bodies detached from the main army; also a combat between two individuals, distinct from a duel, being without premeditation.

RENDER, in Law, a term used in the levying of a fine.

RENDERING, is usually expressed of a complicated tackle, lanyard, or lashing, when the effect of the power applied is communicated with facility to all the parts without being inter-

rupted. It is therefore used in contradistinction to jamming or sticking fast.

RENDEZVOUS, the port or place of destination, where the several ships of a fleet or squadron are appointed to join company, or to rejoin in case of separation.

RENDEZVOUS, a name given to any house where a press-gang resides, and volunteers are invited to enter into the navy. Also, a place appointed to meet in, at a certain day and hour.

RENDLING CURD, in rural economy, a term used to signify the broken curd in cheese-making.

RENEGATE, a person who has apostatized from the Christian faith, and embraced some other mode of religion, particularly Mahometanism.

RENITENCY, in Philosophy, is that force in solid bodies, by which they resist the impulse of other bodies, or re-act as much as they are acted upon.

RENNET, in rural economy, a term applied to the coagulum for making cheese. It is prepared from the bag, maw, or stomach of the young calf, by a salt pickle. The preparations are various; but in the making of cheese much depends upon having a good sweet rennet.

RENT, is a certain profit issuing yearly out of lands and tenements corporeal. There are at common law three kinds of rents; rent service, rent charge, and rent seek, or rack rent: Rent service is where the tenant holds his land of his lord by fealty and certain rent; or by homage, fealty, and certain rent; or by other service and certain rent; and it is called a rent service because it has some corporeal service incident to it, which at least is fealty. Rent charge is so called because the land for payment of it is charged with a distress. Rent seek, or rack rent, is where the land is granted without any clause of distress for the same. The time for payment of rent, and consequently for a demand, is such a convenient time before the sun-setting of the last day, as will be sufficient to have the money counted; but if the tenant meets the lessor on the land at any time of the last day of payment, and tenders the rent, that is sufficient tender, because the money is to be paid indefinitely on that day, and therefore tenders on that day is sufficient.

RENTAL, a roll in which the rents of a manor are entered, and from which they are collected, and the amount is ascertained.

REPAIR, the operation of repairing any injuries, or supplying any deficiencies, which a ship may suffer from age, battle, storm, accident, &c. The repair is necessarily greater or smaller in proportion to the loss which the vessel has sustained. Accordingly a suitable number of the timbers, beams, or planks, or a sufficient part of either, are removed, and new pieces fixed in their places. The whole is completed by breaming, caulking, and paying the body with a new composition of stuff. See **BREAMING**, &c.

REPARTEE, a ready smart reply, especially in matters of wit, humour, or rally.

REPEALING, in Law, the revoking or annulling of any statute, deed, &c.; but no act of parliament can be repealed in the same session in which it was made.

REPEATING Mechanism, in Horology, is a mechanical contrivance, by which a clock or watch is made to repeat the hours and quarters of existing time, so that a person in the dark, or in bed, may know the time by night, as well as by day. Barlow, a clock-maker of London, in 1676, had the honour of this invention.

REPEAT SIGNALS, *To*, is to make the same signal with the admiral, in order to its being more readily distinguished at a distance, or through smoke, &c. *To Repeat a Signal*, sometimes implies to repeat a signal over again, on account of its not having been attended to the first time. The repeat is usually accompanied with a gun.

REPEATING-SHIP, is a vessel (usually a frigate) appointed to attend each admiral in a fleet, and to repeat every signal he makes, with which she immediately sails the whole length of the fleet or squadron, if the signal is general, or to the ship for which it is intended, if particular, and then returns to her station near the admiral's ship.

REPELLENT MEDICINES, are those which prevent such an afflux of fluids to any part as would excite tumor or inflammation, or to diminish that already produced.

REPELLING Power, in Physics, is a power or faculty residing in, and exerted by, the minute particles of natural bodies, by which they mutually recede from each other.

REPERCUSSION. See REFLECTION.

REPERTORY, a place in which things are orderly disposed, so as easily to be found when wanted. Hence, indices of books are repertories.

REPETEND, in Arithmetic, denotes that part of an infinite decimal which is continually repeated *ad infinitum*, and is otherwise called a *circulate*.

REPETITION, in Music, denotes a reiterating or playing over again the same part of a composition, whether it is a whole strain, part of a strain, or double strain, &c.

REPETITION, in Rhetoric, a figure which gracefully and emphatically repeats either the same word, or the same sense in different words.

REPLANTING, in Gardening, the act of planting trees, shrubs, or flowers, a second time. Many plants require this process, to prevent them from degenerating.

REPLEADER. Whenever a replader is granted, the pleadings must begin *de novo* at that stage of them, whether it is the plea, replication, rejoinder, or whatever else, wherein there appears to have been the first default or deviation from the regular course.

REPLEGIARE, a writ brought by one whose cattle are distrained and put in pound by another, upon security given the sheriff to pursue or answer the action at law, against the distrainer.

REPLETION, in the Canon Law, is where the revenue of a benefice is sufficient to fill or occupy the whole right of the graduate who holds it. Where there is repletion, the party can demand no more by virtue of his degrees.

REPLEVIN, in Law, is a writ by him who has cattle or other goods distrained by another, for any cause. If he wishes to dispute the propriety of the distress, he sues this writ, and upon putting in surety to the sheriff, that upon delivery of the thing distrained, he will prosecute the action against the distrainer, the cattle or goods are delivered back, and are said to be replevied. In this writ, or action, both the plaintiff and defendant are called actors; the one, that is the plaintiff suing for damages, and the defendant, who is also called avowant, to have a return of the goods or cattle. If the replevin be determined for the plaintiff, namely, that the distress was wrongfully taken, he has already got his goods back into his own possession, and shall keep them, and recover damages. But if the defendant prevail, by the default or non-suit of the plaintiff, then he shall have a writ *de returno habendo*, or to have a return, whereby the chattels which were distrained and then replevied, are returned again into his custody, to be sold, or otherwise disposed of, as if no replevin had been made. If the distress were for damage feasant, that is, for cattle breaking through fences, and coming upon the land of the party, the distrainer may keep the goods so returned, until tender shall be made of sufficient amends.

REPLICATION, in Logic, the assuming or using the same term twice in the same proposition.

REPLICATION, an exception or answer of the plaintiff in a suit to the defendant's plea; and is also that which the complainant replies to the defendant's answer in chancery, &c.

REPORT, in Law, is a public relation of cases judiciously argued, debated, resolved, or adjudged, in any of the king's courts of justice, with the causes and reasons of the same, as delivered by the judges.

REPOSE, in Painting, certain masses or large assemblages of light and shade, which being well conducted, prevent the confusion of objects and figures, by engaging and fixing the eye, so that it cannot attend to the other parts of the painting for some time; and thus leading it to consider the several groups, gradually proceeding from stage to stage.

REPOSE, *Angle of*, an angle of 35°.

REPOSITORY, a storehouse, or place where things are laid up or kept.

REPRIMAND, a sharp authoritative reproof. In military discipline a reprimand is deemed a severe punishment.

REPRESENTATION. There is a heir by representation, where the father dies in the life of the grandfather, leaving a

son, who shall inherit the grandfather's estate, before the father's brother, &c.

REPRESENTATIVE, one who personates or supplies the place of another, and is invested with his right and authority. The Commons are presumed to be the representatives of the people in parliament.

REPREVE, to suspend a prisoner from the execution and proceeding of the law at the time.

REPRISAL, or **REPRIZE**, is the retaking a vessel from the enemy soon after the first capture, or at least before she has arrived in any neutral or hostile port. If a vessel thus retaken, has been twenty-four hours in the possession of the enemy, she is deemed a lawful prize; but if retaken within that time, she is to be wholly restored to the owner, upon his allowing one-third of her value for salvage to the recaptors. Also, if a vessel has, from any cause, been abandoned by the enemy before he has taken her into any port, she is to be restored to the original proprietor.

REPRIZE, or **REPRIZE**, at sea, is a merchant ship which, after its being taken by a corsair, privateer, or other enemy, is retaken by the opposite party. If a vessel thus retaken has been twenty-four hours in the hands of the enemy, it is deemed a lawful prize; but if it be retaken within that time, it is to be restored to the proprietors, with every thing therein, upon his allowing one-third to the vessel who made the reprise. Also, if the reprise has been abandoned by the enemy, either in a tempest or any other cause, before it has been led into any port, it is to be restored to the proprietor.

REPRODUCTION, is usually understood to mean the restoration of a thing before existing, and since destroyed. It is very well known that trees and plants may be raised from slips and cuttings; and some late observations have shewn that there are some animals which have the same property. The polype (See HYDRA) was the first instance we had of this kind; but we had scarcely time to wonder at the discovery M. Trembley had made, when M. Bonett discovered the same property in a species of water-worm. Among the plants which may be raised from cuttings, there are some which seem to possess this quality in so eminent a degree, that the smallest portion of them will become a complete tree again. A twig of willow, poplar, and many other trees, being planted in the earth, takes root, and becomes a tree, every branch of which will in the same manner produce other trees. The case is the same with these worms; they are cut to pieces, and each separate piece becomes a perfect animal; and each of these may be again cut into a number of pieces, each of which will in the same manner produce an animal. The reproductions of several parts of lobsters, crabs, &c. is one of the greatest curiosities in natural history. It seems indeed inconsistent with the modern system of generation, which supposes the animal to be wholly formed in the egg, that, in lieu of an organical part of an animal cut off, another should arise perfectly it: the fact, however, is too well attested to be denied.

REPTILIA, in Natural History, an order of Amphibia, the character of which is, that they breathe through the mouth, have feet, and flat naked ears without auricles. There are five genera; viz. Draco, Siren, Lacerta, Tertudo, Rana.

REPUBLIC, a popular state or government; or a nation where the body or only a part of the people have the government in their own hands. When the supreme power is possessed by all the body, it is called a democracy; when it is lodged in a part of the people, it is called an *aristocracy*.

REPULSION, in Physics, that property in bodies, whereby, if they are placed just beyond the spheres of each other's attraction of cohesion, they mutually recede and fly off. Thus, if any oily substance lighter than water, be placed upon its surface, or if a piece of iron be laid upon mercury, the surface of the fluid will be depressed about the body which is laid on it: this depression is manifestly occasioned by a repelling power in the bodies, which prevents the approach of the fluid towards them. But it is possible, in some cases, to press or force the repelling bodies into the sphere of each other's attraction; and then they will mutually tend toward each other, as when we mix oil and water till they are incorporated. Dr. Knight defines repulsion to be that cause which makes bodies mutually endeavour to recede from each other with different forces at different times;

and that such a cause exists in nature, he thinks evident for the following reasons: 1. Because all bodies are electrical, or capable of being made so; and it is well known that electrical bodies both attract and repel. 2. Both attraction and repulsion are very conspicuous in all magnetical bodies. 3. Sir Isaac Newton has shewn from experience, that the surface of two convex glasses repel each other. 4. The same great philosopher has explained the elasticity of the air, by supposing its particles mutually to repel each other. 5. The particles of light are in part at least repelled from the surfaces of all bodies. 6. Lastly, it seems highly probable that the particles of light mutually repel each other, as well as the particles of air. Dr. Knight also ascribes the cause of repulsion, as well as that of attraction, to the immediate effect of God's will; and as attraction and repulsion are contraries, and consequently cannot at the same time belong to the same substance, the doctor supposes there are in nature two kinds of matter, one attracting, the other repelling; and that those particles of matter which repel each other, are subject to the general law of attraction in respect of other matter. A repellent matter being thus supposed, equally dispersed through the universe; he attempts to account for many natural phenomena by this means. He thinks light consists of this repellent matter put into violent vibrations by the repellent corpuscles which compose the atmosphere of the sun and stars; and that, therefore, we have no reason to believe they are gulfs of fire, but, like the rest of the heavenly bodies, inhabitable worlds. From the same principles he attempts to explain the nature of fire and heat, the various phenomena of the magnet, and the cause of the variation of the needle; and, indeed, it is difficult, if not impossible, by the doctrine of attraction alone, to account for all the phenomena observable in experiments made with magnets, which may be solved by admitting this doctrine of a repellent fluid; but whether it will be sufficient to account for all the particular phenomena of nature, which is the proper test of an hypothesis, time and experience alone must determine. The doctor also endeavours to shew that the attractions of cohesion, gravity, and magnetism, are the same, and that by those two active principles, viz. attraction and repulsion, all the phenomena of nature may be explained; but as his ingenious treatise on the subject is laid down in a series of propositions connected together, it would be impossible to do justice to his arguments without transcribing the whole: we shall therefore refer the curious reader to the book itself. According to Gravesand and others, when light is reflected from a polished spherical surface, the particles of light do not strike upon the solid parts, and so rebound from them; but are repelled from the surface at a small distance before they touch it, by a power extended over such polished surface.

REQUESTS, COURT OF, an ancient court of equity instituted about the nineteenth year of Henry VII.

REQUIEM, a mass sung in the Romish church for the rest of the soul of the deceased.

RESCRIPT, an answer delivered by an emperor or pope, when consulted by particular persons, on some difficult question, or point of law, to serve as a decision thereof.

RESCUE, or **RESCOUS**, is the forcibly freeing another from an arrest, or some legal commitment; which being a high offence, subjects the offender not only to an action at the suit of the party injured, but likewise to fine and imprisonment at the suit of the king.

RESERVE, BODY OF, or *corps de reserve*, in Military Affairs, the third or last line of an army drawn up for battle.

RESERVOIR, a large pond or enclosure of water, artificially made, in order to collect and retain it for the use of canals, mills, and occasional streams. Reservoirs are applied to various other purposes in agriculture and domestic economy.

RESIDENCE, in an ecclesiastical sense, is the continuance of a parson or vicar on his benefice.

RESIDUAL ANALYSIS, a branch of analysis invented by Landen, and applied by him to the solution of those problems which are more generally solved by the doctrine of fluxions. This method was called the residual analysis, because in all cases where it is made use of, the conclusions are obtained by means of residual quantities. In this analysis a geometrical or physical problem is reduced to another purely algebraical; and the solution is then obtained without any suppo-

sition of motion, and without considering quantities as composed of infinitely small particles. The residual analysis proceeds by taking the difference of the same function of a variable quantity in two different states of that quantity, and expressing the relation of this difference to the difference between the two states of the said variable quantity itself. This relation being first expressed generally, is then considered in the case when the difference of the two states of the variable quantity is $= 0$.

RESIDUAL QUANTITY, in Algebra, is a binomial connected by the sign $-$; thus $a - b$; $a - \sqrt{b}$, &c. are residual quantities.

RESIDUAL FIGURE, in Geometry, the figure remaining after subtracting a lesser from a greater.

RESIDUE, or **RESIDUUM**, that which is left after taking the part of any thing away, being much the same as remainder, the former being applied to quantity in the same sense as the latter is to number.

RESIGNATION, in the Canon Law, the surrendering a benefice into the hands of the collator, or bishop.

RESIGNATION, or *Resignee*, in Law, the person to whom the thing is resigned.

RESIN. The name resin is used to denote solid inflammable substances, of vegetable origin, soluble in alcohol, usually affording much soot by their combustion. They are likewise soluble in oils, but not at all in water, and are more or less acted upon by the alkalis. All the resins appear to be nothing else but volatile oils, rendered concrete by their combination with oxygen. Resin, analyzed by M. M. Gay Lussac and Thénard, was found to consist of: Carbon, 75.944; hydrogen, 10.719; water, 15.156; oxygen 13.337; hydrogen in excess, 8.9. The resin of fir is known by the name of rosin. Its properties are well known. Its specific gravity is 1072. It melts readily, burns with a yellow light, throwing off much smoke. Resin is insoluble in water either hot or cold, but very soluble in alcohol.

RESISTANCE, of the fibres of solid bodies, is more properly called cohesion.

RESISTANCE, or *Resisting Force*, in Physics, any power which acts in opposition to another, so as to destroy or diminish its effect. Resistances are of various kinds, arising from the nature and properties of the resisting bodies, the circumstance in which they are placed, and the laws by which they are governed. These may be divided into the following cases:

1. The resistance between the surfaces of contiguous solid bodies, generally denominated friction. See **FRICTION** and **ADHESION**.
2. The resistance between the contiguous particles of the same body, whether fluid or solid; for the laws of which see **COHESION** and **STRENGTH**.
3. The resistance that solid bodies oppose to penetration; for which see **PENETRATION** and **REPULSION**.
4. The resistance of elastic and non-elastic fluids to the motion of bodies moving in them. The principles of which we will endeavour to illustrate in the present article. The resistance which a body experiences from the fluid medium through which it is impelled, depends on the velocity, form, and magnitude of the body, and on the inertia and tenacity of the fluid. For fluids resist the motion of bodies through them,
 1. By the inertia of their particles.
 2. By their tenacity, or the adhesion of their particles.
 3. By the friction of the body against the particles of the fluid.

In perfect fluids, the latter causes of resistance are very inconsiderable, and therefore are not commonly considered. But the first is always very considerable, and obtains equally in the most perfect and in the most imperfect fluids. In what follows, and in all cases of a similar description, it will be necessary to distinguish between resistance and retardation; the former being the quantity of motion, and the latter the quantity of velocity which is lost; therefore the retardations are as the resistances applied to the quantity of matter, and in the same body they have always the same constant ratio to each other. In fluids of uniform tenacity, the resistance from the cohesion of its particles is as the velocity with which the body moves. For since the cohesion of the particles is constantly the same in the same space, whatever may be the velocity, the resistance from this cohesion will be as the space described in a given time, that is, as the velocity. In a fluid whose parts yield easily

without disturbing each other's motions, and which flows in behind as fast as a plane body moves forward, the resistance will be as the density of the fluid; for in this case the pressure on every part of the body is the same as if the body were at rest.

RESOLUTION, in Chemistry, &c. the reduction of a mixed body into its component parts, or first principles, by a proper analysis.

RESOLUTION, in a general sense, denotes the dividing or separating any compound quantity or thing into its original component parts.

RESOLUTION of Equations, in Algebra, is the determination of the values of the unknown letters or quantities of which the equation is composed; in order to which, it is necessary first to exterminate or eliminate all the unknown quantities but one of the equation, and then the value of the remaining quantity is to be found by the proper rules for this purpose, viz. by the rules given for simple, quadratic, cubic, or biquadratic equations, according to which of these it may belong; or by the general method of approximation; for which see the respective articles.

RESOLUTION of Motions and Forces. See PARALLELOGRAM of Forces.

RESPIRATION, is the act of receiving a portion of air into the lungs, and again emitting it. The blood of the veins is charged with a portion of carbon which it emits in the lungs, and this carbon uniting with the oxygen received in the lungs, forms carbonic acid gas, and is emitted, as is also the nitrogen or azote. The volume of carbonic acid discharged is exactly equal in bulk to the oxygen which has disappeared, and it is hence supposed that no oxygen is absorbed by the lungs; but other philosophers have been of a contrary opinion, and have supposed that the change of the colour of purple of the venous blood into red, in the arterial blood, which takes place on passing through the lungs, was attributable to the absorption of oxygen, whilst, on the other hand, this has been attributed solely to the discharge of the carbon. An ordinary sized man consumes about 46,000 cubic inches of oxygen per day, and makes 20 respirations in a minute. The quantity of carbonic acid formed during respiration is diminished after swallowing intoxicating liquors, or under a course of mercury, nitric acid, or vegetable diet.

RESPITE, in Law, &c. a delay, forbearance, or prolongation of time, granted to any one for the payment of a debt. In criminal cases, it is the suspension of a sentence, as to the time of its being executed. In knight service, it is the dispensing with the homage of a vassal, on certain conditions, and during a given time.

REST, in Physics, the continuance of a body in the same place, either absolutely or relatively, viz. its continuance in the same part of absolute space, or in the same part of relative space; and is hence denominated absolute or relative rest. It is, however, highly probable, that in its most extensive sense there is no such thing as absolute rest in the whole creation, at least we know of nothing in such a state.

RESTING GROUND, the omission of crops for a given period, that the soil may recover its primitive fertility, which constant tillage tends to impoverish.

RESTITUTION, in Physics, the returning of elastic bodies, forcibly bent, to their natural state. In a moral sense, restitution, reinstates a person in his rights, or restores something that had been unjustly taken from him. In law, it is a returning of stolen goods.

RESULTANT, in Mechanics, is used to denote that single force, or the line represent the quantity and direction of that single force, which is equivalent to two or more forces whose quantities and directions are given.

RETAINER, in Law, a servant who does not continually dwell in the house of his master, but only attends upon special occasions.

RETAINING FEE, the first fee given to a sergeant or counsellor at law, in order to make him sure, and prevent his pleading on the contrary side.

RETALIATION, the act of returning like for like. It is excited by aggression, and frequently leads to civil wars.

RETARDATION, any force tending to diminish the velocity of moving bodies.

RETARDATION may arise either from the effect of resistance, or from the action of gravity. For that which arises from the former, and for the distinction between resistance and retardation, see RESISTANCE.

RETARDATION, from Gravity, is peculiar to bodies projected upwards, which have their velocities diminished, by precisely the same laws as falling bodies have theirs accelerated. Thus, if a body be projected perpendicularly upwards, with a velocity which would, independently of gravity, cause it to ascend a feet per second; it will, in consequence of the action of gravity, have its velocity so diminished, that, at the end of the first second, it will be only $(a-32)$ feet, or at the end of the second it will be only $(a-64)$ feet, &c. Hence, to find the greatest height to which a body will ascend when projected perpendicularly upwards with any given velocity, the time of ascent, &c. it is only necessary to find the space through which a body must fall to generate that velocity, and the time it would be in descending through that space, which will be precisely the same as the height through which it will ascend, and the time of its ascent. See ACCELERATION.

RETCHING, in Sickness, an effort or endeavour to vomit.

RETENECE, in the Materia Medica, a name used to express the common resin of the pine or fir tree, and sometimes common black pitch.

RETENTION, is defined, by Locke, to be a faculty of the mind, whereby it keeps or retains those simple ideas it has once received by sensation or reflection.

RETENTION, is also used, in medicine, &c. for the state of contraction in the solids or vascular parts of the body, which makes them hold fast their proper contents.

RETI, in Hindoo Mythology, is a personification of affection, and the fabled consort of Kama the god of love.

RETICULA, or **RETICULE**, the name of an instrument formerly employed for measuring the number of digits eclipsed in either luminary; its construction depends on nearly the same principles as that of the MICROMETER.

RETINA, in Anatomy, a membrane of the eye, formed by an expansion of the optic nerve, and constituting the immediate organ of vision. See EYE.

RETINASPALTUM, in Mineralogy, a name given to an inflammable kind of resinous substance accompanying Bovey coal. On the first application of heat, it melts and smokes, and then burns with a bright flame.

RETINUE, the attendants or followers of a prince or person of quality, chiefly on a journey.

RETIRED LIST, a list on the marine establishment, on which superannuated officers are placed. Officers on the retired list of the East India service, have several advantages over others.

RETORT, in Chemistry, is a kind of round-bellied vessel, made of earth, glass, or metal, having a crooked neck or beak to which the recipient is fastened. Retorts are of essential service in distillations, and most frequently for those which require a degree of heat superior to that of boiling water.

RETRAXIT, in Law, is where the plaintiff comes into court in person, either alone or with the defendant, and declares he will proceed no further in his action. When this is done the same action can never be renewed.

RETREAT, in Gardening, is an erection or arbour, a nook or recess, formed either for pleasure or convenience. In its formation, utility and beauty should go hand in hand.

RETREAT, the order or disposition in which a fleet or squadron declines engagement, or flies from a pursuing enemy.

RETREAT, in War, is the retiring or retrograde motion of an army from its former position. The skill of a commander is generally more conspicuous in his retreats than in his advances and engagements. The retreat of the ten thousand Greeks under Xenophon has been the subject of universal admiration. The most remarkable retreats in modern times have been that of Moreau in 1796, through Swabia; that of Macdonald in Italy; and that of Sir John Moore in Spain, in 1800-1810.

RETRENCHMENT, in the art of War, any kind of work raised to cover a post, and fortify it against the enemy.

RETROACTIVE, in Law, that which has an operation or influence on time and transactions that are past.

RETROGRADATION, or **RETROGRESSION**, in Astronomy, is an apparent motion of the planets, by which they seem to

move backward in the ecliptic, or in *antecedentia*, or contrary to the order of the signs. When a planet moves in *consequentia*, or according to the order of the signs Aries, Taurus, Gemini, &c. it is said to be *direct*. When it appears for a few successive days in the same place or point of the heavens, it is said to be *stationary*. And when it goes in *antecedentia*, or contrary to the order of the signs, it is said to be *retrograde*.

Both the superior and inferior planets are subject to this apparent irregularity in their motions; but it arises from different causes, as may be illustrated as follows:—Let *C D c d* represent the orbit of the earth, and *A B a b* that of any inferior planet, as Venus; now when the earth is at *c*, and Venus at *A*, the former being moving towards *d* with a less velocity than the latter is towards *B*, it is obvious, that the apparent motion of Venus, as referred to the heavens *M N*, will be from *M* towards *N*, or according to the order of the signs. But if, when the Earth is at *c*, Venus is at *a*, then her apparent place in the heavens will be at *N*; and when the Earth is arrived at *d*, Venus will have come to *b*, and her apparent place in the heavens will be at *M*, and consequently during this time she will appear to be moving in the heavens from *N* to *M*, viz. contrary to her former motion, which motion being in *antecedentia*, or contrary to the order of the signs, is then said to be *retrograde*. Whence it appears that when an inferior planet is in, or nearly in its superior conjunction, its apparent motion is direct, but when in its inferior conjunction, its apparent motion is retrograde, and for a few days between these two she has no apparent motion, and is therefore said to be stationary.

With regard to the superior planets, it is obvious that their retrogradation must happen when they are in opposition; thus, if we now suppose *A B a b* to be the orbit of the earth, and *C D c d* that of Saturn, and suppose that when the latter is at *C*, the former is at *A*, then the apparent place of Saturn in the heavens will be at *n*; but the motion of the Earth exceeding that of Saturn, when we are arrived at *B*, he will only be got to *D*, and his apparent place will be at *m*; and therefore during this interval his apparent motion will be retrograde. Whereas it is obvious that had the earth been at *a*, instead of being at *A*, as we have supposed above, that is, if Saturn had been in conjunction, its apparent motion in the heavens must have been contrary to the former, or in *consequentia*, or according to the order of the signs; and for a time between these two motions he must necessarily have appeared stationary, as is obvious without any particular illustration. The periods of retrogradation of the several planets are not always the same, but at a mean they are nearly as follows:—Saturn 140 days, Jupiter 120 days, Mars 73 days, Venus 42 days, and Mercury 22 days.

RETROCESSION of the Equinoxes. See PRECESSION.

REVE, REEVE, or Greve, the bailiff of a franchise, or manor, thus called, especially in the west of England.

REVEILLE, a beat of drum about break of day, to give notice that it is time for the soldiers to arise, and that the sentries are to forbear challenging.

REVELS, entertainments of dancing, masking, acting comedies, farces, &c.

REVENUE, PUBLIC, the portion of the general income of a state, which is appropriated to the payment of national expenses. The ordinary revenue of the early kings of England consisted of the following branches:

1. Rents and profits of the crown-lands.
2. Profits from military tenures. As a great part of the lands in England were subject to knight-service, the profits incident to this tenure were very great, besides the extraordinary contributions to which they were liable, for making the king's son a knight, and for marrying his eldest daughter.
3. The custody of the lay revenues, with the lands and tenelements of bishoprics during their vacancy.
4. First-fruits, and tenths of all spiritual preferments. These revenues are now vested in trustees for ever, as a fund for the augmentation of poor livings, and form what is usually called Queen Ann's Bounty.

5. Purveyance and pre-emption, or a right of buying up provisions and other necessities, for the use of the royal household, at an appraised valuation, in preference to all other persons, and even without the consent of the owner; also of forcibly impressing carriages and horses for the king's use at a settled price. The purveyors greatly abused their authority, and were of little advantage to the crown; Charles II. therefore at his restoration, agreed to resign this prerogative, with the military tenures; and the Parliament, in lieu thereof, settled on him and his successors for ever a tax on beer and ale, afterwards commonly called the hereditary excise.

6. Fines and forfeitures of various descriptions; also fees to the crown in a variety of legal matters.

7. The right to all shipwrecks; to treasure-trove; to royal fish, that is, whales and sturgeons, when thrown ashore, or caught near the coast; to all mines of silver or gold; to waifs or goods stolen and thrown away by the thief in his flight; and estrays, or animals found wandering, and the owner unknown; and to deadlands and forfeitures of lands and goods for offences. These rights, producing little profit, have since been mostly granted away to the lords of manors and other liberties.

8. Escheats of lands upon the defect of heirs to succeed to the inheritance, in which case they reverted to the king.

9. The custody of idiots and lunatics, the profits of whose lands were received by the king, an allowance being made to them for necessities.

From these sources, the produce of the remaining branches of which is now very insignificant, the kings of England derived the whole of their ordinary revenue, till commerce raised the produce of the customs into importance, and the parliament ventured to grant the principal part of their produce to the king, for life. Upon extraordinary occasions, Henry II. and some of his successors, had recourse chiefly to scutages, which were a composition of those who held knights' fees, in lieu of the military service to which they were bound, as the king and the persons liable could agree: hydrag and talliage were taxes of the same nature, upon other lands and upon other cities and boroughs. Tenths and fifteenths were originally the real tenth or fifteenth of all the moveables belonging to the subject; the amount was uncertain, being levied by new assessments on every fresh grant, till the 8th Edward III. when a new assessment was made and recorded in the exchequer, which was the real value at that period of every city, borough, and town in the kingdom, and by this the fifteenths were afterwards levied according to the specific sums therein stated, which were usually raised in different places by a common rate on all the inhabitants. Subsidies were a grant introduced about the time of Richard II. and Henry IV. This mode of taxation fell into disuse during the civil wars in the reign of Charles I. when the parliament introduced weekly and monthly assessments, at a fixed sum upon each county, which was levied by a pound rate both upon land and personal estates. The commonwealth afterward introduced excise duties, and derived some profit from the establishment of the post office, both of which have been since improved into very productive sources of revenue.

The various duties now constituting the total public revenue of Great Britain, are arranged under the following heads:

1. The Custom, which consist of duties on goods imported, on goods exported, on goods carried coastways, and a tonnage duty.
2. The Excise, which consists principally of duties on malt liquors of every kind, including the distillery; many other articles are, however, likewise included, as candles, leather, soap, starch, tea, coffee, wine, tobacco, salt, glass, printed goods, and bricks and tiles.
3. Stamp Duties, laid on deeds and documents of almost every description.
4. Land and Assessed Taxes. In 1709 a scheme was adopted for the redemption of the land tax, for which purpose an act was passed, making the tax perpetual; it was then offered for sale to the proprietors of the lands upon which it was charged, or, if they declined it, to any other persons who chose to become a purchaser. The consideration to be given in either case was not to be in money, but in the three per cent. stock: the object of the scheme being to absorb a large quantity of floating stock, and thus facilitate the raising of new loans. It

was estimated that this measure would transfer about eighty millions of stock to government, but the terms offered were by no means such as to induce a general approval of it, and the total amount of stock transferred for land-tax redeemed on the first of February, 1808, was only 22,976,829*l.* 10*s.* 4*d.* of course a very considerable portion of the tax still remained unredeemed. The assessed taxes consist of the duties on houses, windows, servants, carriages, horses, and horse-dealers, dogs, hair powder, and armorial bearings.

5. The Post Office. King James I. originally erected a post office for the conveyance of letters to foreign parts, previously to which an establishment of this kind had existed for the conveyance of inland letters.

6. Sixpence in the pound on pensions and salaries.

7. One shilling in the pound on pensions and salaries.

8. Hackney coaches.

9. Hawkers and pedlars.

In addition to these several branches of the public revenue, there are some small branches of the old hereditary revenue still remaining. These consist chiefly of alternation fines, post fines, seizures of uncustomed and prohibited goods, compositions, profers and the crown lands, of which the last is by far the most important.—*Watkins's Cyclopædia.*

REVERBERATION, in Physics, the act of a body repelling or reflecting another after its impinging on it. Hence, *echoes* are occasioned by the reverberation of sounds from arched obstacles. In glass furnaces the flame reverberates, or bends back again, to burn the matter on all sides. In Chemistry, reverberation denotes a circulation of flame, or its return from the top to the bottom of the furnace, when calcination is required.

REVERENCE, in Ethics, is the veneration or high degree of respect which is paid to superior sanctity, by a conscious inferiority of moral worth.

REVERSE, of a medal, coin, &c. denotes the second or back side in opposition to the head or principal figure.

REVERSED, in Heraldry, a thing turned backwards or upside-down.

REVERSION, a sum of money, estate, annuity, or any other kind of property, the possession of which is not to be obtained till after the expiration of a certain period of time, or till some event, as the failure of a life or lives has happened. The present value of such property depends greatly on the current interest of money, for if money produced only three per cent. interest, a person giving 1000*l.* for a reversionary estate relinquishes an annuity of 30*l.* but if he could make five per cent. interest of his money, he gives up an annuity of 50*l.* and consequently in the latter case he would expect a greater reversion than the former. The true value of a reversion therefore is that present sum which, if improved at a given rate of interest, would, at the period when the reversion comes into possession, amount to its then actual value. This, with respect to sums receivable at the end of a certain number of years, is easily found by the Table of INTEREST. Thus, if a person is entitled to 500*l.* at the end of ten years, and wishes to know its present worth: the value of one pound to be received at the end of this term, is, by the Table, 613913, which multiplied by 500, gives 326*l.* 19*s.* 1*d.* for the present value of the reversion.

REVERSION OF SERIES, in Algebra, is the method of finding the value of the root or unknown quantity, whose powers enter the terms of a finite or infinite series, by means of another series in which it does not enter.

REVERSING OF MOTIONS, *Contrivances for.* We shall here mention some methods of reversing motions after long intervals; as is the case of drawing up buckets from wells or mines, where no change of direction may be required for several minutes; or in different kinds of mill work, where the direction may not be changed for some hours.

Contrivances to effect such reversion of motion are very numerous; but almost all of them may be reduced to two general methods; for the required change is generally produced either by making two equal pinions on one and the same axis, taken alternately into the teeth of those parts of a larger wheel which are nearly diametrically opposite; or, by means of an additional wheel, which may, as the practical mechanics term it, be thrown in and out of gear alternately. In many engines for drawing buckets out of mines that are moved by horses, the

motion is frequently reversed by turning round the animal, and causing him to retrace his steps and draw the contrary way; but this is found very injurious to the horse, a circumstance which has frequently led to the adoption of other methods. In Emerson's Mechanics, a simple contrivance is described, consisting merely of a horizontal face wheel, upon the same vertical shaft as the horse-pole is attached to, and two equal pinions upon the same axle as carries the drum or barrel on which the rope winds. The axle which carries the drum and pinions is fixed horizontally, a little above a diameter of the face wheel; and first one, and then the other, of the pinions is made to be driven by that wheel; thus, manifestly, reversing the motion as required. There are two methods of attaching these pinions to the axle, and making them to be acted upon by the face-wheel: in one of them, the pinions are fastened upon the axle, at a distance from each other exceeding the diameter of the face wheel only three or four inches; then, the axle being moved horizontally through this small distance, brings first one and then the other pinion into contact with the wheel at opposite extremities of a diameter, and thus changes the direction of the motion; but this method is attended with the disadvantage of having often to move a heavy weight with the horizontal axle, besides that there is much danger of breaking the teeth of the pinions and wheel when they first come to embrace each other. In the second method, the lanterns or pinions both turn constantly with the face wheel, but they play freely upon their common axle, except that they are stopped by a pin which *fixes* them; the application of such pin to first the one, and then the other, of the lanterns, produces the alternating motion as proposed.

M. Prony has two contrivances for reversing the motion in horse-whims, without changing that of the animal: in both of which, however, the general principle is the same as that adopted by Emerson. In the first, a horizontal wheel, toothed at its face, lay just above two vertical pinions, fixed on the opposite extremities of an axis of the length of its diameter. This wheel was so contrived as to incline a little from its horizontal position to either side at pleasure; so that on the one inclination, its teeth locked with those of one pinion, and receded from the other; and on the other position, its operation on the pinions was reversed; by which, the axis of the pinions turned round first in one direction, and afterwards in the contrary. Prony, finding this method subject to some inconveniences, contrived the following, which he esteems much superior to it. A horizontal wheel, toothed at its face, and attached to a perpendicular arbor, (which gives it motion,) turns two pinions, moveable on the same axis, which it meets at the opposite sides of its circumference: these pinions are not attached to the axis, but turn round freely upon it: the intermediate part of the axis is square, and has, adjoining to each pinion, boxes which slide back and forwards on it, each of which support a faced wheel, with strong serrated teeth; the serration being in a different direction on the opposite wheels: the boxes are connected by two iron bars, so as to change their places by one movement; to the pinions there are also serrated faced wheels attached, so as to lock on those opposite to them on the sliding boxes. From this construction it follows, that when the boxes are slid to one extremity of the axis, the pinion at that side will be connected with the axle, and communicate its motion to it in one direction; and when the boxes are moved to the other extremity, then the first pinion will be disengaged, and the second be locked to the axle, and cause it to turn round in a direction the reverse of that in which it moved before. There is a lever on another axle, whose office is to move the before-mentioned boxes backwards and forwards; an arm projects from the axis, which moves between two pieces, proceeding from the frame connected with the boxes; the lever rises upwards, and has a weight at its top, by which it presses strongly in either direction, when it passes the perpendicular position; forming thus the contrivance vulgarly called a tumbling bar, which is used in various engines for a similar purpose. Upon the same axle on which the pinions move is fastened a drum wheel, round which passes the chain or cord to which the buckets are attached; another chain or cord is placed below the buckets, from the bottom of one to that of the other, to form an equilibrium between the whole of the appendage of one bucket and that of the other in all positions. A bar is so placed, that,

on one of the buckets rising to a certain height, it catches the bar, forces it upwards, and thereby throws over the tumbling bob connected with its other extremity: this reverses the movement of the buckets; and, on the other bucket rising, it operates in the same way on another lever, which throws the bob to the other side, and causes the first bucket to rise again.

Prony has annexed a contrivance to this engine, by which the horse that puts it in motion is disengaged, when any accident happens which would tend to stop the movement of the wheels: for this purpose, the traces pass under two pulleys in the ends of the yoke; and their extremities, which have loops wrought in them, are alternately attached to two pins in a roller, round which a cord is wound two or three turns, and passes from thence through rings in the lever, (which causes the arbor to revolve,) and over a pulley on the arbor to a weight which hangs beside it. When the draught exceeds this weight, it is evident the roller will be drawn round by the traces, and that they will slip off the pins, and be disengaged during the first revolution.

The method of reversing motion by causing pinions to be operated upon by the opposite parts of a face-wheel, has been long known and practised by millwrights; and they have various contrivances for performing the alternation, as by levers, screws, tumbling bobs, &c. One of these will be illustrated by a figure, when we come to the article *TIDE MILL*.

As to the second general method, it has, perhaps, an appearance of greater simplicity; though, when reduced to practice, it is commonly found more expensive than the former. Suppose, that while the horizontal wheel A, in the annexed figure, continues to turn always one way, it is required to have the horizontal wheel B turn, sometimes in one direction, and sometimes in another; by means of an additional wheel C, equal in diameter and number of teeth, (supposing the velocities in both directions to be equal,) this may be accomplished, thus:—Let the two wheels B and C have the lower pivots of their axes resting in boxes or cases that may be moved up and down by means of screws; and, while the wheels A and B are nearly of equal thickness, let the wheel C be somewhat more than double the thickness of either: when the motion of the wheel B is to be in a contrary direction to that of A, let the wheel C be lowered so much that its teeth play neither into those of A nor B, while the teeth of A take into those of B, and drive it round; when, on the contrary, B is to be moved in the same direction as A, let the wheel B be lowered till its teeth do not come into contact with those of A, and let C be raised until the upper parts of its teeth take between those of the wheel A, while the lower parts of the other teeth play into the teeth B; so shall the rotation of B have the direction required. If the motion of the wheel A were sometimes in one direction, and sometimes in another, the motion of B might, all along, be preserved in one direction, by the occasional application of C as an intermediate wheel.

REVIEW, in Chancery, is used for a bill where a cause has been heard, and a decree thereon signed; but some error in law appearing upon the decree, or new matter being discovered after it was made, this bill is given for a fresh examination into the merits of the cause.

Review, in War, is the appearance of an army, or part of an army, in order of battle, and their being viewed by the general, that he may know the condition of the troops.

Review, is also the name of one kind of periodical publications, now too much prostituted (under the shelter of anonymous criticism) to the purposes of the malice of rival authors, and the petty artifice of interested booksellers.

REVISE, among Printers, a second or third proof of a sheet to be printed; taken off in order to be compared with the last proof, to see whether all the mistakes marked in it are actually corrected.

REVIVOR, BILL OF, in Chancery, is a bill for reviving a cause, where either of the parties dies after the bill and answer, and before the cause is heard; or if heard, before the decree is enrolled; in which case the bill must be brought, praying that the former proceedings may stand revived, and be put on the same footing as at the time of the abatement.

REVOCATION, in Law, signifies the recalling, or annulling and making void, some power, grant, deed, &c. made before.

REVOLUTION, the motion of a body or line about a centre which remains fixed.

Period of REVOLUTION, in Astronomy, is the time a planet, comet, &c. employs in passing from any point in its orbit to the same point again. This, with regard to the earth, is what determines the length of the year. See *YEAR*. And for the times of revolution of the other planets, see *PERIOD* and *PLANET*.

REYNEAU, CHARLES RENE, a reputable French mathematician, was born in 1650 at Brissac, in Anjou. He taught philosophy at Pezenas and Toulon; and in 1683 was appointed to the mathematical professorship at Angers, where he died in 1728, at the age of 78 years.

RHABDOLOGY, a name given by Napier to his method of performing multiplication, division, &c. by means of small bones or rods. See *Napier's RODS*.

RHAPSODI, in Antiquity, persons who made a business of singing or reciting pieces of Homer's poems. Cuper says, that the rhapsodi were clothed in red when they sung the Iliad, and in blue when they sung the Odyssey.

RHAPSODOMANCY, an ancient kind of divination, performed by fixing on a passage of some poet at hazard, and then reckoning on it as a prediction of what should come to pass.

RHEA AMERICANA, the American ostrich, in size is very little inferior to the common one; the bill is sloped not unlike that of a goose, being flat at the top and rounded at the end; the eyes are black, and the lids furnished with hairs; the head is rounded, and covered with downy feathers; the neck is two feet eight inches long, and feathered also; from the tip of one wing to that of the other extended, the length is eight feet; it cannot fly, but it runs very swiftly; the legs are stout, and bare of feathers above the knees, and furnished with three toes, all placed forwards, each having a straight and stout claw as in the cassowary; on the heel is a callous knob serving in the place of a back toe; the general colour of the plumage is dull gray mixed with white, inclining to the latter on the under parts; the tail is very short, and not conspicuous, being entirely covered with long loose and floating feathers, having its origin from the lower part of the back and rump, and entirely covering it; the bill and legs are brown.

RHETICUS, GEORGE JOACHIM, a distinguished German astronomer, and mathematician, was born at Feldkirk in the Tyrol, in 1514, and for some years assisted the celebrated Copernicus in his astronomical labours. He died in 1576, near 63 years of age.

RHETORIC, in the most extensive sense of the word, denotes the art of composition, or that which enables us to apply language or speech to the best possible advantage. According to etymology, which often affords the most satisfactory explanation of words, it signifies the art of pouring forth a stream of sentiment, and communicating with fluency our feeling and thoughts to others. Taken in this point of view, rhetoric will comprehend all polite literature, poetry perhaps excepted, the belles-lettres of the French, the pathetic and pleasant of every kind; compositions whose aim and end is not so much to inform or satisfy the understanding, as to move, incline, and persuade, by addressing the imagination, the affections, and in some measure sensation itself. There cannot be a better rule for composition, and one more plain and practical, than what is laid down by Cicero: "We are first to consider what is to be said; secondly, how; thirdly, in what words; and lastly, how it is to be ornamented." See the Editor's Grammar of Rhetoric and Polite Literature, Dr. Hugh Blair's "Rhetoric," Dr. Campbell's Philosophy of Rhetoric, &c.

RHEUM, RHUBARB, a genus of the monogynia order in the euneandria class of plants, and in the natural method ranking under the 12th order, holoracea. There is no calyx; the corolla is sixfid and persistent; and there is one triquetrous seed. There are seven species.

RHEUMATISM, a well-known painful distemper, coming, as is supposed, from acrid humours.

RHINOCEROS, in Natural History, a genus of mammalia of the order Feræ. Generic character: horn solid, perennial, conical, seated on the nose, but not adhering to the bone. This quadruped is exceeded in size only by the elephant. Its usual

length, not including the tail, is twelve feet; and the circumference of its body nearly the same. Its nose is armed with a horny substance, projecting, in the full-grown animal, nearly three feet, and is a weapon of defence, which almost secures it from every attack. Even the tiger, with all his ferocity, is but very rarely daring enough to assail the rhinoceros. Its upper lip is of considerable length and pliability, acting like a species of snout, which, grasping the shoots of trees and various substances, conveys them to the mouth, and it is capable of extension and contraction at the animal's convenience. The skin is, in some parts so thick and hard as scarcely to be penetrable by the sharpest sabre, or even by a musket ball. These animals are found in Bengal, Siam, China, and in several countries of Africa, but are far less numerous than the elephant, and of sequestered solitary habits. The female produces only one at a birth; and at the age of two years the horn is only an inch long, and at six only of the length of nine inches. It is generally, however, quiet and inoffensive. Its food consists entirely of vegetables, the tender branches of trees, and succulent herbage, of which it will devour immense quantities. It delights in retired and cool situations, near lakes and streams, and appears to derive one of the highest satisfactions from the practice of rolling and wallowing in mud; in this respect bearing a striking resemblance to the hog.

This animal was exhibited by Augustus to the Romans, and is supposed to be the unicorn of the scripture, as it possesses the properties ascribed to that animal, of magnitude, strength, and swiftness, in addition to that peculiarity of a single horn, which may be considered as establishing their identity. The two-horned rhinoceros, is similar in size and manners to the former, and is principally distinguished from it by having two horns on its nose; the first being always the largest.

RHINOCEROS AVIS, in Ornithology, a name given to a species of Indian raven, the beak of which being remarkably fine, and having a horn-like protuberance on its upper part, is frequently brought to Europe. It is an ugly bird, has a very rank smell, is larger than the English raven, and feeds on carrion.

RHINOMACER, a genus of insects, of the order coleoptera.

RHODIUM, a new metal discovered among the grains of crude platina by Dr. Wollaston.

RHODORA, (*Canadian Rose-blossom*), a genus of the decandria monogynia class and order.

RHOMBOIDES, in Geometry, a quadrilateral figure, whose opposite sides and angles are equal, but which is neither equilateral nor equiangular; or it is an oblique angled parallelogram.

RHOMBOIDIA, the name of a genus of spars, given them from their being of a rhomboidal form. They derive this figure from an admixture of particles of iron, and consist of six planes.

RHOMBUS, in Geometry, an equilateral rhomboid, or a quadrilateral figure, whose sides are equal and parallel, but the angles unequal; the two opposite ones being obtuse, and the other two acute.

RHUBARB. See **RHEUM**.

RHUMB, in Navigation, a vertical circle of any given place, or the intersection of such a circle with the horizon, in which last sense the rhumb is the same with the point of the compass.

RHUMB LINE, or *Loxodromia*, in Navigation, is a line prolonged from any point in a sea chart, except in the direction of any of the four cardinal points; or it is the line described by a ship while her course is constantly directed towards one and the same point of the compass, except the four above mentioned, that is, while she crosses all the meridians at the same angle, providing this is not a right one, and this angle is called the angle of the rhumb; and that which it makes with the equator, or a parallel to the equator, is called the complement of the rhumb. If a vessel sail either north or south, it evidently describes a great circle of the sphere, or part of such a circle; and if her course is either due east or due west, she cuts all the meridians at right angles. But if her course is oblique to these principal points, then she no longer describes a circle, but a sort of spiral, the characteristic property of which is, that it cuts all the meridians at the same angle, and is thence denominated the loxodromia, or loxodromic curve, or rhumb line, which, though it continually approaches towards the pole, can never arrive at it, except after an infinite number of revolutions.

RHYME. See **POETRY**.

RHYTHMICAL, in Music, an epithet applied to the property, or quality, in the ancient melopoeia, and modern melody, by which the cadences, accents, and quantities, are regulated and determined.

RIBAND, or **RIBBON**, a narrow sort of silk, chiefly used for head ornaments, badges of chivalry, &c.

RIBANDS, in Naval Architecture, long, narrow, flexible pieces of timber, nailed upon the outside of the ribs from the stem to the stern-post, so as to encompass the ship lengthways; of these the principal are the.

Floor RIBAND, which terminates at the height of the rising line of the floor; and the

Breadth RIBAND, which coincides with the wing transom, at the height of the lower-deck: all the rest are termed intermediate ribands.

The ribbands being judiciously arranged with regard to their height and distance from each other, and forming regular sweeps round the ship's body, will compose a kind of frame, whose interior surface will determine the curve of all the intermediate or filling timbers, which are stationed between the principal ones. As the figure of a ship's body approaches to that of a conoid, and the ribbands having a limited breadth, it is apparent that they cannot be applied to this convex surface without forming a double curve, which will be partly vertical and partly horizontal, so that the vertical curve will increase by approaching the stem, and still more by drawing near the stern post. It is also evident, that by deviating from the middle line of the ship's length, as they approach the extreme breadth at the midship frame, the ribbands will also form a horizontal curve. From this double curve it results that the ribbands will appear in different points of view when delineated on different planes of the same ship.

RIBES, the currant and gooseberry bush, a genus of the monogynia order in the pentandria class of plants, and in the natural method ranking under the 36th order, pomaceæ.

RIBS of a Parrel, are short pieces of plank, each having two holes in it, through which the two parts of the parrel-rope are received, the inner smooth edge of the rib resting against and sliding readily up and down the mast.

RICCIOLI, **JOANNES BAPTISTA**, a learned Italian astronomer and mathematician, was born at Ferrara, a city in the papal dominions, in 1598, and died in 1671, in the 73d year of his age.

RICHERIA, a genus of the class and order dioecia pentandria; a tree of great size.

RICINUS, or **PALMA CHRISTI**, a genus of the monadelphina order, in the monoecia class of plants, and in the natural method ranking under the 38th order, tricoceæ.

RICKETS, a disease affecting children, and principally characterized by enlargement and inflexure, or distortion of the bones.

RICOCHE Firing, in the Military art, is a method of firing with pieces elevated from three to six degrees, and loaded with a small charge, so that the ball may bound and roll along inside the parapet. The ball or shot thus discharged, goes bounding or rolling, killing or maiming all it meets with in its course, and creates much greater disorder, by thus moving slowly, than if thrown from the piece whose elevation is greater, with much greater violence.

RIDDLE, in rural economy, a sort of sieve, used to separate the grain from dust, and the seeds of weeds. In Mineralogy, the riddle is used to separate the ore from surrounding rubbish.

RIDE (To) Head to Wind, is when the wind is so much more powerful than the tide, as to cause the ship to swing till her head is in the direction of the former.

To Ride Athwart, or *between Wind and Tide*, is when the wind and tide are in opposition, but so nearly equal in their force, that the ship rides with the tide running against one side, and the wind blowing upon the other.

To Ride out a Gale, signifies that the ship does not drive during the storm.

To Ride Easy, is said of a ship when she does not labour or feel a great strain upon her cables.

To Ride Hard, is, on the contrary, to pitch violently in the sea, so as to strain her cables, masts, or hull.

To Ride a Head-rope of a Sail, &c. is to shake and stretch it by treading upon it while a purchase is employed at the end

to extend it. A rope is said to ride when one of the turns by which it is wound round lies over another, so as to interrupt the operation, or prevent its rendering.

RIDERS, a sort of interior ribs, fixed occasionally in a ship's hold, opposite to some of the principal timbers to which they are bolted, and reaching from the keelson to the beams of the lower-deck, and sometimes higher, in order to strengthen her frame. They are bolted to the other timbers to support them when it is apprehended the ship is not sufficiently strong in the part where they are fixed, which is generally a-midships. They have also their floor pieces and futtocks, and sometimes their top pieces, and being scarfed to each other in the same manner as the timbers, they have similar distinctive appellations, as the *Rider Futtocks*; *Lower Futtock RIDERS*; *Middle Futtock RIDERS*; *Upper Futtock RIDERS*; *Floor RIDERS*. See the article *Floor*. The riders ought to be stationed so as to lie between two ports of the lower deck, and to correspond with the timbers to which they are attached, in such manner as that the scarfs of the riders may be clear of the timbers. They are scored upon the keelson, clamps, and thick stuff of the bottom. They are secured by bolts, which are driven from without, so as to penetrate the outside planks, the timbers, the clamps, and the riders, on the inside of which last they are fore-locked. These pieces are rarely used in merchant-ships, on account of the space they occupy in the hold; neither are they generally used in vessels of war, at least, till the ship is enfeebled by service.

RIDGE, a long narrow assemblage of rocks, lying near the surface of the sea.

RIDGES, in Agriculture, are pieces of ground laid up between two furrows, having always considerable length, but of small breadth.

RIDING, a corruption of *Trithing*, now chiefly used as divisions of Yorkshire, of which there are three.

RIDING Clerk, one of the six clerks in chancery, who, in his turn annually keeps the controlment books of all grants that pass the great seal that year.

RIFLE, a firm-arm which has the inside of its barrel cut with from three to nine or ten spiral grooves, so as to make it resemble a female screw, varying from a common screw only in this, that its grooves or rifles are less deflected and approach more to a right line; it being now usual for the grooves with which the best rifled barrels are cut, to take about one whole turn in a length of thirty inches. The number of these grooves differ according to the size of the barrel and the fancy of the workman; and their depth and width are not regulated by any invariable rule.

RIG, To, is to fit the shrouds, stays, braces, &c. to their respective masts and yards.

To Rie in a Boom, is to draw it in from a situation upon the end of a yard, bowsprit, or another boom, &c. to extend the foot of a sail.

RIGGERS, men who make a livelihood by going on board ships to fit the standing and running rigging. It is also a name given in the navy to any party of men sent to the rigging loft or bulk, to prepare the standing rigging for putting over the mast-heads.

RIGGING, a general name given to all the ropes employed to support the masts, and to extend or reduce the sails, or arrange them to the disposition of the wind.

Standing RIGGING, is that which is used to sustain the masts, and remains in a fixed position; as the shrouds, stays, and back-stays.

Running RIGGING, is that which is fitted to arrange the sails, by passing through various blocks in different places about the masts, yards, shrouds, &c. as the braces, sheets, halliards, clew-lines, &c. &c.

Lower RIGGING, is that which attaches to the lower masts.

Top-Mast RIGGING, consists of the top-mast shrouds, stays, and back-stays.

RIGGING-Loft, a kind of long room or gallery in a dock yard, where the standing rigging is fitted by stretching, serving, splicing, seizing, &c. to be in readiness for the ship.

RIGHT, in Geometry, signifies the same with straight; thus a straight line is called a right one.

RIGHT, in Law, not only denotes property, for which a writ of right lies, but also any title or claim, either by virtue of a

condition, mortgage, &c. for which no action is given by law, but an entry only.

RIGHT ANGLE, *Cone*, *Cylinder*, *Sphere*, &c. See their respective substantives.

RIGHTING, the act of restoring a ship to her upright position after she has been laid upon a careen, which is effected by casting loose the careening tackles, and, if necessary, heaving upon the relieving-tackles.

A ship is also said to right at sea, when she rises with her masts erect, after having been pressed down on one side by the effort of the wind upon her sails.

To RIGHT the Helm, implies to replace it in the middle of the ship, after having put it out of that position.

RIGHTS, *BILL OF*, a declaration delivered by the lords and commons to the Prince and Princess of Orange, Feb. 13, 1688, and afterwards enacted in parliament, when they came to the throne. This may be considered as one grand foundation of English liberty.

RIGIDITY, a brittle hardness; or that kind of hardness which is supposed to arise from the mutual indentation of the component particles of a body.

RILL, in Agriculture, a small runlet of water, mostly rising on the sides of gentle declivities; they are sometimes natural, and sometimes artificial.

RIM, or **BRIM**, a name given to the circular edge of a top. The circumference or circular part of a wheel.

RIND, a skin of any fruit that may be cut off. The outer coat of the chesnut set with prickles, particularly has this name.

RING, for the finger, an ornament of great antiquity and general use, frequently used as badges of office, and denoting the quality of the wearer.

RING, in Navigation and Astronomy, a brass instrument made in the form of a ring, and serving to take the altitude of the sun.

RING BOLT, an iron bolt with an eye at one end, wherein is fitted a circular ring. They are used for various purposes, but more particularly for managing and securing the cannon; and are, for this purpose, fixed in the edges of the gun-ports. They are driven through the plank and the corresponding beam or timber, and retained in this position by a small pin thrust through a hole in the small end.

RING Ropes, short pieces of rope, tied occasionally to the ring-bolts of the deck, to stopper or fasten the cable more securely when the ship rides with a heavy strain.

RING Tail, a quadrilateral sail extending on a small mast, which is occasionally erected for that purpose on a ship's taffarel, the lower part being stretched out by a boom, which projects over the stern horizontally.

RING Tail, is also the name of a kind of studding sail hoisted beyond the afteredge of those sails which are extended by a gaff and a boom over the stern. The two lower corners of this sail are stretched out to a boom called a

RING Tail Boom, which rigs in and out upon the main or driver boom, in the same manner that a studding sail boom does on the top-sail yards.

RING Worm, in Medicine, a popular appellation given to various superficial affections of the skin, which assume somewhat of a circular form. The kinds are very different, and require very different treatment.

RING of SATURN, in Astronomy, is a broad, opaque, circular body, encompassing the equatorial regions of that planet, at a considerable distance from him; which presents, under favourable circumstances, one of the finest telescopic objects in the heavens. An apparent irregularity was first observed in the form of Saturn by Galileo, but his telescope was not sufficiently powerful for him to discover the cause of it; this, however, was soon after effected by Huygens, who, in consequence, published his "*New Theory of Saturn*," in 1659. This ring, which is very thin, not exceeding 4500 miles, is inclined to the plane of the ecliptic in an angle of $31^{\circ} 19' 12''$; and revolves from west to east in $10^{\text{d}} 20^{\text{h}} 16^{\text{m}} 8^{\text{s}}$, being nearly the time of the diurnal revolution of Saturn, and which is also found, from the laws of Kepler, to be the time in which a satellite would revolve about that planet at the mean distance of the ring; a very remarkable confirmation of the universality of the laws of the planetary motions. This rotation is performed about an axis perpendicu-

lar to the plane of the ring, and passing through the centre of the planet. The ring being, as we observed above, very thin, it sometimes nearly disappears, that is, when its plane coincides with or passes through the centre of the earth or sun, at which time it subtends an angle of not more than half a second, and can therefore only be discovered by the most powerful telescopes, through which it has then the appearance of a luminous line beyond the body of the planet. And as this plane is presented to the sun twice during each sidereal revolution of the planet, the disappearance of the ring will happen about every 15 years, and at nearly the same intervals it will appear to the greatest advantage. When viewed in the most favourable position, with a magnifying power of 700, the ring is observed to be divided into two unequal portions by a black concentric line, which is now ascertained to be a real separation, and that what we call the ring of Saturn consists at least of two rings; and some astronomers have even supposed it to be still farther subdivided, and to consist of several circular parts, but this at present is little more than conjecture. The dimensions of this double ring, as given by Dr. Herschel, are as follow:—

	Eng. Miles.
Diameter of the planet,	76068
Inside diameter, smaller ring,	146345
Outside,	184393
Inside diameter, larger ring,	190248
Outside,	204883
Breadth of the inner ring,	20000
— of the outer ring,	7200
Space between the rings,	2839
— between the planet and ring,	70277
Mean thickness of ring,	4500

The intersection of the plane of the ring with the ecliptic is in $5^{\circ} 20'$, and $11^{\circ} 20'$, in which points therefore it disappears, and between these, viz. at $2^{\circ} 20'$, and $8^{\circ} 20'$, it appears most brilliant. As the plane of the ring coincides, or nearly coincides, with the equator of the planet, it is obvious that the ring never becomes visible in his polar regions, and even in those parts nearer the equator it must be very frequently eclipsed by the planet, which last, on the contrary, is as frequently eclipsed by the ring; whence it does not seem that it can be designed to supply these remote regions with light, as some have supposed, as it rather serves to render them more dreary and comfortless; well might the poet say,

“One moment's cold like theirs would pierce our bone,
Freeze our heart's blood, and turn us all to stone.”

RIOT, rout, and unlawful assembly. When three persons, or more, assemble themselves together, with an intent mutually to assist each other against any who shall oppose them in the execution of some enterprise of a private nature, with force or violence, against the peace, or to the manifest terror of the people, whether the act intended were of itself lawful or unlawful; if they only meet with such purpose or intent, though they shall after depart of their own accord without doing any thing, this is an unlawful assembly. By 34 Edward III. c. 1, it is enacted that if a justice find persons riotously assembled, he alone has not only power to arrest the offenders, and bind them to their good behaviour, or imprison them if they do not offer good bail; but he may also authorize others to arrest them by a bare verbal command, without other warrant: and by force thereof, the person so commanded may pursue and arrest the offender in his absence, as well as presence. It is also said, that after any riot is over, any one justice may send his warrant to arrest any person who was concerned in it, and that he may send him to gaol till he shall find sureties for his good behaviour. The punishment of unlawful assemblies, if to the number of twelve, may be capital, according to the circumstances which attend them; but from the number of three to eleven, it is by fine and imprisonment only. The same is the case in riots and routs by the common law, to which the pillory, in very enormous cases, has been sometimes superadded.

By the act 1 George II. cap. 5. sect. 2, every justice, sheriff, mayor, &c. shall, upon notice of a riot, or unlawful tumultuous assembly of twelve persons, proceed to the place, and make proclamation for them to depart, upon pains of that act commonly called the riot act. If any person shall wilfully oppose or hurt any person going to make proclamation, and prevent

the same, he shall be guilty of felony without benefit of clergy. If twelve continue together after proclamation for one hour, it is felony in like manner. And every justice, &c. shall apprehend persons; and if the rioters are killed, the justice, &c. shall not answer for it. A riot, though of fewer persons than twelve, to destroy any church, chapel, meeting, or dwelling-house, out-house, &c. is a capital felony; and the hundred shall answer the damages as in case of robbery.

If two justices go out to quell a riot, they may assemble the *posse comitatus*, and every person capable of travelling is, upon being warned, to join them on pain of imprisonment. 13 Henry IV. c. 7, s. 1, 2, 11, 5, c. 8, s. 2.

It is no uncommon thing to hear, when accidents have occurred at riots, that though the riot act has been read by a magistrate, the people who suffer, or those who make their appearance before a coroner's jury, for the most part swear they never heard one syllable of the act read. In order to announce that the riot act has really been read, the editor once proposed to Viscount Lord Sidmouth, that a flag should be unfurled by the magistrate, or his officer, when the riot act had been read to a seditious or ill-disposed mob. They could all see the flag, who were not blind, though they might not all hear the magistrate's voice, and would be left without excuse, if they did not disperse when the symbol of good order was unfurled in their sight.

RIPPLING, a broken and interrupted noise, produced by a current on or near the sea-coast: the effect of which is also apparent to the eye, by occasioning an ebullition or bubbling up of the water.

RISING, in Astronomy, the first appearance of the sun, moon, or other celestial body, above the horizon.

RISING Line, a name given by shipwrights to an incurvated line drawn on the plane of elevation, to determine the height of the ends of all the floor timbers throughout the ship's length and which accordingly ascertains the figure of the bottom with regard to sharpness or flatness.

RISK, the hazard or chance of loss, damage, &c. against which insurances are generally effected; such as against fire, seas, tempest, enemies, &c.

RITUAL, a book directing the order and manner to be observed in celebrating religious ceremonies and performing divine service, in a particular church, diocese, order, or the like.

RIVER, in Geography, a stream or current of fresh water, flowing in a bed or channel from its source or spring into the sea. In Commerce and Political Economy, we may define a river to be a moving road, and the nurse of canals or inland navigation. The doctrine which relates to the flux, reflux, motion, and discharge of rivers, is a branch of hydraulics, and as such forms a part of the present work, though our limits will only admit of a slight sketch of the theory. Water running in open canals or rivers, is accelerated in consequence of its depth, and of the declivity on which it runs, till the resistance increasing with the velocity, becomes equal to the acceleration, when the motion of the stream becomes uniform. But this resistance, it is obvious, can only be determined by experiment; and hence several philosophers have undertaken different courses of experiments for this purpose, amongst whom Buat and Leslie seem to have met with the most complete success.

The same principles which regulate the motion of water in pipes and along canals, extend likewise to the flow of rivers in their beds. Since the propelling power is proportional to the elevation of the main source, the celerity acquired by these descending streams would become enormous, if the force were not gradually absorbed by the operation of some constant impediments. Suppose, such a river as the Rhone to receive its principal waters at the altitude of 900 feet above the level of the sea, and that no system of obstruction had intervened in its course, it would have shot into the Bay of Marseilles with the tremendous velocity of 240 feet in a second, or at the rate of 164 miles every hour. Even an inferior stream, like the Thames, fed at the height of only a hundred feet, would still, if not retarded by the attrition of its bottom and sides, have rushed into the sea with a velocity of 54½ miles in an hour. The resistance of fluids, like the friction of solids, thus enters largely into the economy of nature. As the latter is the great principle of stability and consolidation, so the former serves most essentially to restrain the accumulation of celerity, and to moderate

all violent motions. A current presses forwards with increasing rapidity, till the obstruction which it encounters becomes at last equal to the inciting force; and having attained this limit, the water then continues to flow in a uniform stream. The maintaining power is proportional to the quantity of descent in a given space; but the impeding influence depends on the surface of the bed of the river compared with its volume. This obstruction must augment very fast, being as the square of the celerity. If a river should wind considerably, the multiplied deflexions which it suffers, must still farther impede its motion. In every bend which it makes, part of its impulse will be spent against the concave side of the channel; the centrifugal effort will likewise raise the surface of the water in those sinuosities, and therefore augment the abrasion of the banks. Hence, no stream can be long confined to a rectilinear channel. If an accidental swell should once effect a breach, the sweep of the current must necessarily tend to enlarge the concavity by an accelerating progression; the opposite shore, from the accumulation of gravel and other deposits, gradually advancing into the channel. Rivers thus naturally form sinuosities; they seek to meander over the plains; and they would incessantly change their beds, if not restrained by sedulous attention and skilful hydraulic operations. In such a country as Italy, the superintendence of water-courses constitutes an important department of government.

If a flat surface be directly opposed to the action of a stream as it shoots from the side of a vessel, it must evidently sustain a pressure just equal to that which actually projected the fluid, or the load of the incumbent column. In every case, therefore, the impulsion of any current against a perpendicular plane, may be estimated by the weight of a body of the fluid standing upon that surface, and having the altitude due to the velocity.

The pressure of a river against the piers of a bridge, may be hence computed. The shock becomes augmented in a high ratio during floods; for not only is a greater extent of surface then opposed to the current, but the effort on every given space follows also the square of the increased velocity. The mighty rush of a torrent, carrying along with it fragments of rock, stones, or gravel, depends on the same principle. A torrent, with the celerity of eight miles an hour, would therefore be capable of rolling a stone of four foot in diameter. But a stream gliding at the rate of two miles an hour, would only be sufficient to carry along with it a pebble of three inches in diameter. With lower velocities, the current will scarcely move gravel. If the particles of sand were supposed to have a diameter equal to the twenty-fourth part of an inch, it would require a flow of a quarter of a mile in an hour to bear them along. A velocity of the tenth part of a mile in an hour, would only be sufficient to carry sandy particles of the hundred and twenty-third part of an inch in diameter. Hence the theory of the washing of metallic ores, and the deposition of gold dust in the beds of rivers. The ores being broken into very small fragments by means of a stamper, these are laid upon an inclined plane, and exposed to the action of a descending stream of water, which sweeps away all the lighter earthy particles. In like manner the pellicles of gold, adhering commonly to minute portions of quartz, being at length detached by incessant rolling, are left in the little pools, while the sandy particles are still carried farther. Hence also the reason why the bottoms of rapid rivers are covered with large round stones, or at least with rolled pebbles. Where the celerity of the current becomes moderated, gravel and coarse sand begin to appear. But when the flow is sluggish, the bed of the river is always covered with fine sand or mud. Such deposits occur chiefly in the pools, and near the influx into the sea. Hence likewise the gradual formation of banks, a process which is constantly going on over all the stagnant parts of water, and along the limits of opposite currents.

The float-board of a river mill is impelled, not by the whole velocity of the stream, but only by the excess of this above the velocity of the board itself. Hence it would be more advantageous to make the float-boards turn slower, and to multiply their velocity afterwards by means of a train of internal machinery. The current might then strike with nearly its full celerity. In the case of undershot wheels, a great loss of power is occasioned by the accumulation of the *dead water*, or

of the water which, having impinged against a float-board, remains nearly stagnant, and therefore impedes the advance of the next float-board. The shock will evidently be the same, whether a current strikes against a fixed plane, or the plane itself moves with an equal and opposite velocity through a fluid at rest. The formula of impulsion already given, must hence include likewise the case of resistance, which is therefore proportional to the square of the celerity. But this conclusion might be derived from direct considerations. As the plane advances, it receives the stroke of all the particles in its progress. The quantity of momentum thus consumed, is evidently compounded of the number of particles encountered, and the impetus of each; but the number and individual force of those particles being as the velocity, the combined effect must be proportional to the square of the velocity.

On Dredging Machines, with a description of one at present employed to deepen the river Clyde.—Dredging was first employed by the Dutch to clean the bars or entrances of their harbours and navigable canals. The first machines were not contrived for lifting mud, gravel, &c. but only for loosening it, so that the sluices constructed for the purpose of cleaning, or scouring, might have more effect. They consisted of large bars, or prongs, placed vertically in a wooden frame, which being fastened to a vessel in the line of the sluices, the whole was impelled forward by the current, and produced a most effectual scour. The first kind of dredging machines used to any extent in this country, consisted of a large plate of iron, about four feet long, and eighteen inches deep, sharpened on the under edge. To each end of it a plank of hard wood was fixed to tenons cut in the iron, whose sharpened edge projected about four inches below the wooden sides, which should be about five long, tapering to ten inches deep at the point, where a bar of iron is fixed to keep the two ends asunder. The whole is formed somewhat like a box, without top or bottom, eighteen inches at one end, and ten inches at the other. To the two ends of the wood a chain is fixed for attaching the principal working rope, or chain. To put the machine in motion, a punt was moored on each bank of the river, directly opposite, and a capstan, or windlass, on each, the one for drawing across the empty dredge, and the other for bringing it back. In the course of its passage, the dredge was commonly filled, and by means of the capstan raised so high, that at low water the stuff could be removed with shovels. Where the shiftings are not frequent, a capstan may be placed on the bank of the river, and the operation carried on as described. Machines on this principle were employed for many years in deepening the Clyde between Glasgow and Dumbarton.

Improved dredging machines, on the principle of an endless chain, were next employed on a large scale, but they have undergone various improvements pointed out by experience. When these machines were first constructed horses were employed as the moving power, which had a circle appropriated to them on board of the vessel that carried the machinery, and were taught to stop by the ringing of a bell. Such machines were long in use in the Humber, at Hull, and in the Clyde at Port-Glasgow and Greenock; those employed at the latter place, had the moving power communicated by men and crane-work. The vessels built for them were very flat, and square at both ends, having an aperture up the middle, through which the bucket-frame works, and the stuff was discharged over the end. The application of the steam-engine, however, as a moving power, soon superseded all other modes of performing the operation. Dredging machines, wrought by steam, have been in use on the Thames, at Hull, Bristol, Sunderland, and Aberdeen, and also on that great national undertaking the Caledonian canal. The one which has been lately constructed by Messrs. Girdwood and Co. in Glasgow, and which is at present employed in deepening the river Clyde, so as to admit of large vessels being brought up, does not differ much in its construction from those employed in the Thames and Caledonian canal.

The figure exhibits an elevation of this machine, with the vessel which contains it. The dredge is situated, in this machine, in the centre of the vessel, which has an opening of about two-thirds of its length from the stern, to allow the machine room to touch the bottom to be deepened. The space on each side of this opening in the vessel is fitted up with hammocks,

&c. for the accommodation of the workmen. The remaining part of the vessel towards the head or bow, is occupied by the steam-engine, boiler, stalk, &c. and the dredge discharges the mud and gravel at the stern. When the engine is set on, the motion is communicated to a wheel fixed on the near end of a horizontal shaft, which conveys the motion to another wheel at the farther end, working into a bevelled wheel on the square barrel or axis on which the buckets revolve. The buckets, twenty-two in number, are placed on the links of two endless chains, connected together by the fastenings of the buckets, and revolving round the bucket frame; the length of each link is made to correspond to the side of the square barrel or axis, revolving in the upper end of the bucket-frame, which is supported on the deck of the stern. A similar square barrel or axis, is placed at the lower end of the bucket frame which is immersed in the water, and is elevated or depressed, according to the depth of the bottom, by a chain and pulleys, the end of which terminates in a barrel turned by the engine, when required. When the process of deepening commences, the lower end of the bucket-frame is allowed to descend till it touches the bottom, so that when each bucket arrives at this end of the frame, it scoops out and takes up a load of mud or gravel, and is carried round by the revolving of the chain. This chain, when loaded with the buckets, is supported on the upper side of the bucket frame, by means of a series of rollers, which prevent the great friction which would otherwise be occasioned by the dragging of the heavy buckets on the frame. As each bucket passes over the upper end of the frame, it discharges its contents into punts brought a stern of the vessel. While this process is going on, the vessel is made to move forward by means of a capstan slowly wrought by four men. This capstan winds in a chain made fast to an anchor considerably ahead of the vessel. The punts are first loaded on the one side, and are then turned round to receive a load on the other; when full, they are floated away to the edge of the river, whence the stuff taken out of the bottom is laid alongside of its banks. The quantity brought up at any time must vary considerably, from the nature and depth of the bottom; we have heard it stated, that 30 tons have been raised in seven minutes, in favourable circumstances.

a, is the engine-house; *b*, a covered wheel, communicating motion from the engine to the shaft *c*, on the other end of which is the shaft-wheel *d*; *e*, is the square barrel or axis, on which the buckets *e, e, e*, revolve; *m*, is the bucket-frame; *n*, the double endless chain; *i, i*, the friction rollers; *r, r*, the regulating chains and pulleys; *l*, the levers for communicating motion to the barrel which moves the chain and pulleys; *p*, the situation of the punts when receiving the mud or gravel raised from the bottom. In the dredging machines used in the Thames, there are two dredges, or endless chains with buckets, one on each side of the vessel, working on the outside, which prevents the necessity of an opening in the centre as above.

RIXDOLLAR, a silver coin in different countries on the continent, and of different values, viz.:—Rixdollar of Basil,

3s. 6½d.; Denmark, 4s. 6½d.; Hamburgh, 4s. 6½d.; Holland, 4s. 6½d.; Lubeck, 3s. 8½d.; Poland, 4s. 0½d.; Prussia, 3s. 0d.; Sweden, 4s. 7½d.; Germany, 4s. 8d. standard of 1566; ditto, 4s. 2d. standard of 1763.

ROACHING of ALUM, one of the last processes used in the making of alum, and rendering it marketable.

ROAD, an open way or passage, forming a commodious communication between one place and another. The ancient Romans were much famed for their attention to roads. Many monuments of their skill and industry still exist, after a lapse of sixteen hundred years.

Common Road.—The exertions made to obtain a smooth surface, is at present one of the most conspicuous features in our system of road-making. This has been effected in a wonderful degree, by a greater attention to the general fabric of the road, and by reducing the metal or stones to smaller dimensions. It must, however, be observed by every one, that our best-formed roads very quickly get out of repair, and that the situation of the traveller is rather tantalizing: for no sooner does he feel the comforts of a smooth path, than an irksome tedium ensues, while he passes along newly laid pieces—the road being almost constantly under repair. Where there is much traffic, it absolutely requires a continued operation, and an unwearied attention, to keep these fine-spun roads in order.

This, indeed, is rendered obvious, even from the quantity of clayey stuff that is raked together in heaps after rains, or is blown about in the state of dust in dry weather. The original cost of a stratum of properly broken road metal, measuring eight inches in depth, in such a situation as Edinburgh, where good rock is to be had in abundance, may be stated to be at the rate of about £2. 10s. per rood of 36 square yards. This course of metal laid upon the several approaches to this city requires to be renewed, or would be wholly worn out, in about three years. In the public streets the waste would be proportionally more rapid; and this seems to render the use of small metal unsuitable for a much frequented thoroughfare. Where it has been tried in some instances in England and South Wales, the inhabitants complain “of having all the dust of summer and all the dirt of winter.”

Causeways.—Were it not for the great expense of causeway, its roughness, and the jarring noise which attends it, this would, no doubt, be generally resorted to both for roads and streets, as is the case in France. The causeway is of two kinds; one termed *ruble*, the other *aisler*. In the former, the stones are irregular both in their figure and dimensions, and they receive hardly any chipping or dressing from the quarrier or pavier. The *aisler* causeway, on the contrary, consists of stones well assembled, carefully hammer-dressed, and laid in the regular courses across the street, upon a bed of sand. This mode was long considered the perfection of road-making. But the stones being formed with the lower end, or that which is set upon the ground, somewhat smaller than the upper surface, they consequently touch only at or near the top. When, therefore, a pressure comes upon one end of a stone so formed, and set in loose sand, it is easily depressed; when the causeway becomes dislocated, and gets into numerous hollows. The dislocation of the *ruble* causeway is still more rapid, as the stones rest upon a smaller surface than either the *aisler* causeway or even the rounded stones in general use in the streets of country towns. These last form a very rough and unpleasant road; but in connexion with the stone-tracks now recommended, they would form most durable and excellent streets.

In the neighbourhood of Edinburgh, the expense of *aisler* causeway is about eight guineas per rood, while *ruble* work may be estimated at about one half of that sum. Perhaps the finest specimens of British paving are those of the Commercial Road of London, Great Sackville-street in Dublin, and Leith-walk of Edinburgh. This last forms almost the only thoroughfare to the Port; it is nearly two miles in length, and its breadth between the curb-stones, which line off a spacious footpath on each side, may be taken at an average of 58 feet. It is now fourteen or fifteen years since it was converted from a very bad common road into this spacious causeway. Although the surface of this street now exhibits many inequalities, yet with a very little repair it has continued a good road during that comparatively long period, and may continue still as long in the same state.

Now, if we compare this with the continual repairs which common roads with a similar traffic demand, we presume that a small metal road would have required to have been renewed every third year, or at least five times, since Leith-walk was paved with asider causeway. Hence it follows, that in the course of fifteen years, this, which cost eight guineas, must, upon a moderate calculation, have cost about fifteen guineas per road, including the expenses of raking mud and other contingencies, to which the causeway is but little incident. We here also lay out of view the inconvenience of repairs almost constantly going on, besides the much greater quantity of dust inseparable from the common road. The causeway is, therefore, upon the whole more economical than the small metal road; but this last is more pleasant for the traveller.

Wheel Tracks of Stone.—If any one can suggest a system of road-making which shall lessen the ultimate expense, and avoid the inconvenience attending the frequent repair of small metal roads, and at the same time secure all the advantages of a smooth and uniform railway, with the duration of the asider causeway, we doubt not that its importance will at once be admitted: and if its practicability be also evinced, we trust that it will soon be brought to the fair test of experiment, the result of which may lead to its general adoption. Mr. Stevenson, who is known to our readers as the constructor of the Bell Rock Light House, has proposed improvements in most common roads, by laying stone tracks of a simple construction, upon a firm foundation, if not throughout the whole extent of our principal roads at least upon all their acclivities which exceed a greater rise than at the rate of 1 perpendicular to 20 horizontal feet. (An undulating line of road, which obliges the carrier, in most instances, to modify his load to one-half of what his horse can take along the more level parts.) It is likewise proposed, that the leading streets of all towns and villages situate upon the principal highways, should be laid with these stone-tracks. The traveller would then glide smoothly along, instead of being accompanied with a thundering noise and jolting motion, most unpleasant to himself, and the inhabitants of the respective places through which he passes.

Perhaps the advantages of this system cannot be better exemplified than by noticing an experiment made in presence of some of the directors of the Forth and Clyde Canal Company, upon a set of cast-iron tracks, laid upon an acclivity rising at the rate of about 1 in 15 to Port-Dundas near Glasgow. Here one horse actually drew up a load of three tons on a cart weighing 9 cwt.* In this case the horse proceeded up hill without much apparent difficulty till he reached the top, and was about to enter on the common causeway, when he could proceed no farther although the road had now become level. The carters frequenting this road agree, that their horses had formerly greater difficulty in taking up 24 cwt. on the causeway, than was now experienced with three tons. How great, therefore, must be the beneficial effects of such an immense acquisition of power as even the partial introduction of wheel-tracks is calculated to afford to the traffic of the country. It is to be regretted that cast-iron, which would be so much more durable than stone, is so expensive. It may also be noticed as a drawback to the use of that material for the thoroughfare of a street, that its property of hardness and of getting smooth, even to a state of polish, becomes proportionally disadvantageous. The stone-tracks, on the contrary, preserve a certain degree of roughness, and the numerous joinings suggested by this plan are also favourable to the safety of the horse.

The individual component stones of the wheel-tracks hitherto

* We trust we shall here be excused for attempting to point out to our readers the benefit of light single horse carts. The team is indeed an emblem of wealth, but it is really impossible to make even two horses work equally. Much as we admire that noble animal, the grey horse of London, we cannot approve of the policy of taking them in teams. Our feelings have, indeed, been often agitated by seeing the whole load of several tons thrown upon the shaft horse at almost every turn from one street to another. We are, however, far from disapproving of four wheels: and with pleasure we notice an improvement lately made in single-horse waggons with four wheels applied to ordinary purposes. These waggons are 10 cwt., on which a horse weighing about 11 cwt., takes a load of 50 cwt. between Edinburgh and Glasgow, a distance of 68 miles. If wheel-tracks were laid upon the principal acclivities of ordinary roads, horses could work with a load of about two tons.

very partially in use, extend from three to four feet in length, are about ten or twelve inches in breadth, and eight or ten inches in depth. In the neighbourhood of Aberdeen there is a granite railway of this description, which runs several miles along, or in conjunction with the common road. The stones of the tracks should be of a cubical form, measuring only from six to eight inches in the lengthway of the track, and twelve to fourteen inches in depth, eighteen inches in breadth at the base, and twelve inches at the top or wheel-track. The stones are therefore proportionate in all their dimensions; for, unless they contain a mass of matter corresponding to their length, they will be found to want strength and stability. It would hardly be possible to keep slender stone-rails in their places, and hence the chief benefit of a connected railway would be lost. On the other hand, very large materials are difficult to be got, and are also more expensive in carriage, and in workmanship, than stones of a smaller size. The Italian wheel-tracks are composed of stones two feet in breadth, and of various lengths. To lessen the risk of horses falling, these broad stones are kept in a rough state, by occasionally cutting grooves with a pick-axe upon their upper surface. A mode of paving with large blocks of granite, chequered or cut in this manner, has been tried in some of the streets of London. In order, however, to give pavement of this kind the necessary stability, the blocks would require to have their dimensions equally large on all sides, the expense of which would be too great. But cubical stones of the size now recommended may be procured at a moderate price, and throughout a great range of country; while the tracks, if properly laid, will actually be more stable than if blocks of larger dimensions were employed. For we may notice, that a carriage wheel rests or impinges even upon a less surface than one inch of its track at a time, in the course of each revolution round its axis; hence it may be conceived to produce a kind of compensating effect, connected with the use of small stones, which prevents the tremour from being communicated beyond the limited sphere of each particular block, and consequently, extending only a few inches. This system of paving was originally proposed for the Main-street of Linlithgow, forming part of the great western road from Edinburgh to Stirlingshire. Notice has since been taken of it in the Transactions of the Highland Society, vol. vi., and in Dr. Brewster's Encyclopedia, under the article "Roads;" and a correct idea of the plan will at once be acquired by examining the following sketch. By using tracks of this description—giving the stones a proportionably broad bed—and laying them upon

a firm foundation, (which is indispensable,) we should have our streets, and the acclivities of our highways, rendered smooth and durable—avoiding, at the same time, the great expense and inconvenience of the common road, and the irksome noise and jolting motion of the causeway. Specimens of these tracks have just been laid in some of the principal streets of Glasgow:

they have also been submitted to the trustees of the county of Edinburgh; and brought under the notice of some of the parishes of London. The tracks may be formed of granite, of

whinstone, (i.e. green-stone or basalt,) or any of the hard varieties of rock capable of being hammer-dressed. Such materials abound in Scotland; in many parts of the north of England, as far south as the approximating sources of the Tees and the Ribble; and in all the districts of Wales. One or more sets of tracks may be laid, according to the nature or extent of the thoroughfare. Let us, for example, suppose that a street, measuring about thirty feet in breadth, be laid out in six compartments, as shewn in the engraving, with a footpath on each side. Three of these compartments are paved with rubble causeway for the horse-paths of the city or town. The remaining three for the highway, are represented as laid with broken stones. The sides of the stones, where they come in contact with each other, are to be dressed so as to form a plain joint across the track, and dressed square, so as to touch throughout the whole surface of the joint. The wheel-track is to be flat, or without any groove, that carriages may move off and on without obstruction. The sides are to be dressed of the sloping form, shewn in the section of the road, but, excepting in the joints across the track and on the top, the stones are only to be hammer-dressed, or chipped after the usual manner. Great care will be necessary, as before noticed, in preparing a firm and compact foundation for the tracks. A stratum of gravel or stone chips, to the depth of three or four inches, laid in lime mortar, according to the nature of the soil, will answer in every case. The laying or building of street stones with mortar, is common in Bath, Paris, and other cities; and unless such a plan be resorted to, the best effects of this system will be lost to the public.

In upholding roads or streets of this description, the intermediate spaces on which the horses go, will seldom require repair. We have seen, in the example of Leith-walk, that aisler causeway has continued in good order for about fifteen years, and, with occasional repairs, may probably last double that period. From this we may conclude, that the tracks will continue for a period of many years. For, although the traffic upon them would be greater than upon the road or street generally, yet it is curious to observe, that however spacious a road may be, carriages are found to go very much in particular lines, one after another; and therefore, the duration of aisler causeway forms a pretty good criterion for judging of the comparative economy of the proposed wheel-tracks. With regard to the expense, we may notice, that in the vicinity of Edinburgh, the lineal yard of two of these tracks will cost about nine shillings, and consequently double of this sum for two sets, to suit carriages travelling in opposite directions. In the ordinary traffic of a city or public road, they may be estimated to last about fifteen years, or as long as three or four strata of common road metal of eight inches in thickness. Not only, therefore, will the comforts of the traveller and those around him be provided for, but the wear and tear of carriage wheels be prevented, and the direct economy of upholding the highways and streets be carried to an immense extent, by the adoption of this system. We are further of opinion, that this system of wheel-tracks is applicable in many situations, where iron railways would either be found too expensive, or where they cannot be introduced with propriety.

During the last few years, public attention has been called to an improved system of road-making, introduced by Mr. Mc Adam. Its chief excellence consists in having a secure foundation or bed, rendered and kept as dry as possible. Over the rough materials, reduced to a given size, are laid in regular strata, in such a position that no water may settle on the surface, or penetrate beneath it, as the stones, being angular, soon unite, and become compact by external and successive pressure. This system of road-making answering every expectation in the country, has lately found its way into London, where in many of the streets the pavement has been torn up, and the stones have been broken by the hammer to the dimensions required. There can be no doubt that carriages run with more ease over roads thus constructed and hardened, than over a rough and unbroken pavement. But when the weather is wet, the streets are frequently covered with mud; and when dry, the inhabitants are much annoyed with clouds of dust. The ultimate advantages of this system in the city, remain yet to be discovered.

Under the article RAILWAY, we have given a general, but brief account of this modern contrivance for aiding the facilities with which carriages heavily laden may be conducted from place to place. So far as general principle is concerned, all railways are the same; but, like most other inventions, they are susceptible of many improvements in subordinate particulars, among which, the following, by Mr. William James, of Thavies Inn, London, is deserving of special notice in this place, as being nearly allied to the preceding observations on roads. These improvements in the construction of rail-roads, or tram-ways, consist first in making the rails hollow, of whatever form circumstances may render most eligible, the object of which is to reduce the quantity of the metal in the rail, and at the same time to retain the required strength; secondly, in a method of producing a rail with a double road-way, to be firmly fixed as the centre of two lines of rail-way, by which contrivance a saving of one rail in four will be effected; thirdly, in affording the means of conducting water, gas, or other fluid, from place to place, through the hollow tube of the rail; fourthly, in employing the hollow rail, as a trunk to receive ropes, chains, or rods passing from a standing engine, or other actuating machine, for the purpose of protecting these ropes or chains from external injury; and, fifthly, in attaching to such rails or tram-ways, certain rods, wheels, and endless chains, for the purpose of drawing or propelling carriages along the said rail-way, which rods and wheels are to be actuated by means of a stationary steam-engine, or other stationary power. The hollow rails are either to be cast in a mould with a suitable core within, as castings are usually done, or welded, rolled, or otherwise formed to the desired external shape, leaving a recess within; or they may be made partly of metal tubes connected to stone or wooden sides or bottoms, so as to leave the internal part hollow.—This contrivance of rendering the rails hollow may be adapted to any external form of rail, and will be found to save a very great portion of the expense of metal, and yet retain the same degree of strength as if solid.

The construction of a double line of road with three rails only, is to be effected by making the middle rail of sufficient breadth to allow two carriages to pass each other. Fig. 1, is a section of two lines of road constructed of three hollow rails, the middle being broad enough to permit the two carriages to pass freely. This contrivance may be extended to a treble line of road, to be formed of four rails instead of six, and so on, by which means a great saving of expense will accrue both in the cost of the rail, and the labour of laying down the lines. The advantages of the broad rail for reducing the number of lines, may be effected without adopting the hollow rail; these central lines may be constructed by joining together pieces of stone, which should be coated with plate iron, or planks of timber.

The employment of such hollow rails for the passage of water, gas, or other fluid, from one place to another, may be advantageously resorted to, where such objects are desirable, without the expense of additional pipes or tubes; and these hollow rails may also be used with great advantage as trunks for conducting chains, rods, or ropes, passing from standing engines, or other machines employed for the purpose of drawing or propelling carriages along the tram-way, which chains, rods, or ropes would by that means be protected from the weather and other external injuries.

The fifth head of the invention respects the attachment of rods, wheels, gear, and endless chains, to such rails or tram-ways, for the purpose of drawing or propelling carriages thereon, by the agency of stationary engines. One mode of effecting

ways, for the purpose of drawing or propelling carriages thereon, by the agency of stationary engines. One mode of effecting

this purpose is shown at fig. 2, which is a plan of a double line or rail-road, and fig. 3, an elevation of the same. Along the central line *a, a*, which is a double rail, a series of rods extend; their extremities being connected together by coupling boxes,

clutches, or other means, so as to enable the whole line of rods to turn as one axle, by the actuating power of a steam-engine, or other moving agent, situated at the extremity or in any convenient part of the line. This power may be applied immediately to the rods, or to the toothed wheel *b*, under the rail-way, which wheel being made to revolve horizontally, and taking into endless screws or pinions upon the rods, cause them to turn. Below the rods the toothed wheel *b* is placed, which revolving horizontally, works into the pinions *c*, fixed upon the rod. Supposing the power of the engine to be communicated to the toothed wheel *b*, by means of a lateral shaft and pinion *d*, the revolution of the wheel *b* would cause the rods *a, a*, to turn, and other wheels similar to *b*, being situated at certain distances apart under the rail-way, would also be made to revolve in a horizontal direction, by means of the several pinions upon the central rods. On the same axle, and under the toothed wheel *b*, is the large drum wheel *e*, which revolves with it; round this, and other similar drum wheels, situate on the axles of the toothed wheels, at certain distances apart, the endless chains *f, f, f, f*, are distended, and by the revolution of the drums these endless chains are carried round, supported upon anti-friction rollers, the endless chains being thus actuated, the carriages upon these roads are drawn forward by means of jointed arms *g, g*, extending from the sides of the carriages, which arms have claws at their lower extremities that drop into and take hold of the links of the chains, and thus by the progress of the chains actuated as above described, the carriages are drawn or propelled along the rail-road; and in order to continue their progress past the breaks where the chains embrace the drums, the arms *g, g*, are set so far apart, that when the foremost arm falls out of action in passing the drum, the hinder arm has still hold of the chain, which continues to drive the carriage forward until the foremost arm has come into action with the next endless chain. Thus a succession of loaded carriages may be advanced along one line of the road, and others returned on the opposite line, by the agency of the endless chains, drums, toothed wheel, and line of rods, actuated by a steam engine, or other moving power, situate at the extremity of the line of rail-road, or any convenient places upon the line. Another mode of impelling carriages upon a similar double line of rails, is proposed by the patentee, varying in a slight degree

from the foregoing. Fig. 4, is a plan of such a line, and fig. 5, is a side view or elevation of the same; *a, a*, is a series of rods passing under the central rail connected together by coupling boxes as above described. At suitable distances apart on these rails are bevelled pinions, taking into other bevel pinions at the inner extremities of the cross shafts *b, b*, and at the outer extremities of these cross shafts are rotatory cross arms *c, c*. On the outer side of each tram carriage a sort of ladder *d, d*, is affixed, by arms extending from the axle trees, and thus by the rotation of the central rods *a*, the cross shafts *b*, with their

arms *c*, are made to turn; and these cross arms *c*, taking into the ladders and pressing against the rollers of which the ladders

are formed, by their rotation drive the carriage forward upon the rail-way.

ROAD, or **ROAD STEAD**, a bay or place of anchorage, at some distance from the shore, on the sea-coast, whither ships or vessels occasionally repair, to receive intelligence, orders, or necessary supplies, or to wait for a more favourable wind, &c.

A **Good ROADSTEAD**, is that which is protected from the reigning winds and the swell of the sea, has a good anchoring ground, and is a competent distance from the shore.

An **Open ROAD**, is one which is not sufficiently enclosed from the wind and sea.

ROADER, or **ROADSTER**, a vessel riding at anchor in a road, bay, or river. If a vessel under sail strike against any roader and damage her, the former is obliged by law to make good the damages sustained by the latter; roaders are careful to anchor at a competent distance from each other, so as not to intercept each other's departure.

ROASTING, in Metallurgy, the separation of volatile bodies from those which are more fixed.

ROBANDS, or **ROPE BANDS**, pronounced **ROBINS**, short flat pieces of rope, having an eye worked in one end: they are used in pairs to tie the upper edges of the square sails to their respective yards; the long leg passing over the yard two or three times round, and the short leg coming under is tied to it upon the yard.

ROBBERY, is a felonious taking away of another man's goods from his person or presence against his will, putting him in fear in order to steal the same. The value is immaterial.—If a man force another to part with his property, for the sake of preserving his character from the imputation of having been guilty of an unnatural crime, it will amount to a robbery, even though the party was under no apprehension of personal danger. If any thing is snatched suddenly from the head, hand, or person of any one, without any struggle on the part of the owner, or without any evidence of force or violence being exerted by the thief, it does not amount to robbery. But if any thing be broken or torn in consequence of the sudden seizure, it would be evidence of such force as would constitute a robbery; as where a part of a lady's hair was torn away by snatching a diamond pin from her head, and an ear was torn by pulling off an ear-ring; each of these cases was deemed a robbery.

By 7 George II. c. 21. If any person shall with any offensive weapon, assault, or by menaces, or in any forcible or violent manner, demand any money or goods, with a felonious intent to rob another, he shall be guilty of felony and shall be transported for seven years.

If any person being out of prison shall commit any robbery, and afterwards discover two or more persons who shall commit any robbery, so as two or more shall be convicted, he shall have the king's pardon for all robberies he shall have committed before such discovery.

Highway robbery differs from robbery only in this, that there is a reward of £40 for the apprehending of the offender, and the horse which the robber rides is forfeited.

ROBERVAL, GILES PERSONNE, an eminent French mathematician, was born in 1602, and died in 1675, at the age of 73.

ROBINS, BENJAMIN, a distinguished English mathematician, was born at Bath, in 1707, and early discovered very superior talents, particularly for mathematical and philosophical subjects, which he afterwards pursued with great success.

ROBUR CAROLINUM, the *Royal Oak*. See **CONSTELLATION**.

ROCK, a stony mass, forming a part of the substance of this globe. Rocks are divided into five classes: namely, 1. Primitive rocks.—2. Rocks of transition.—3. Stratified or secondary rocks.—4. Alluvial depositions.—5. Volcanic rocks.

A Half Tide Rock, a rock which appears above water at half ebb.

ROCK WORK, any sort of work or design which is formed of fragments of rocks, or large stones, in gardens or pleasure grounds.

Rock Butter, in Mineralogy, a saline mineral formed in the fissures of rocks of alum slate. It is a kind of native alum, and feels greasy to the touch, and hence its name.

Rock Cork, a flexible and somewhat elastic mineral, found in mineral veins. It is very soft, cracks when handled, but breaks with difficulty; it is so light as to swim, and is almost infusible with the blowpipe, so that it somewhat approximates to asbestos.

Rock Crystal, the purest variety of the crystallized quartz.

Rock Salt, a natural salt, of the same kind as common table salt. This useful mineral forms large beds and masses in many parts of the world, and even composes entire mountains. In this country, the salt mines of Cheshire are found very productive.

ROCKET, SKY. See FIREWORKS.

ROCKET, Congreve's. This is a new species of war rockets, deriving their name from the inventor, Sir William Congreve. They differ from the common rocket, as well in their magnitude and construction, as in the powerful nature of their composition; which is such, that without the incumbrance of any ordnance, (the rocket containing the propelling power wholly within itself,) balls, shells, caseshot, and carcasses, may be projected to the distance of from 1000 to 3000 yards, which renders them a most efficacious species of artillery; as they may not only be employed in every case, and for every purpose, of the usual light and heavy ordnance, but they are available also in a variety of instances, in which the nature of the ground, or other impediments, prevent the effectual introduction of that arm. These rockets are of various dimensions, as well in length as in calibre, and are differently armed according as they are intended for the field, or for bombardment and conflagration; carrying, in the first instance, either shells or caseshot, which may be exploded at any part of their flight, spreading death and destruction amongst the columns of the enemy; and in the second, where they are intended for the destruction of buildings, shipping, stores, &c. they are armed with a peculiar species of composition, which never fails of destroying every combustible material with which it comes in contact. The latter are called carcass rockets, and were first used at Boulogne, their powers having been previously demonstrated in some experiments made at Woolwich, by Sir William Congreve, in the presence of Mr. Pitt and several of the cabinet ministers, in the month of September, 1805. Sir Sidney Smith was ordered to command the expedition intended for this purpose; but from the lateness of the season, it being near the end of November before the preparations were completed, nothing was done that year. In 1806, Sir William Congreve renewed his proposition for the attack of Boulogne by rockets, which was ordered to be put in execution after Lord Moira, at that time master-general of the ordnance, and Lord Howick, first lord of the admiralty, had satisfied themselves of the efficacious nature of the weapons, from other experiments made again at Woolwich for that purpose. The attack was accordingly made under the command of Commodore Owen, late in October, 1806; having been put off during the summer months, in consequence of the negotiations for peace, at that time pending between the courts of England and France. From this delay, however, instead of being conducted upon the grand scale at first intended, it became a mere desultory attack, in which not more than 200 rockets were fired. The town, however, was set on fire by the first discharge, and continued burning for near two days; it was supposed also that some shipping were destroyed, but the greater part of the rockets certainly went over the basin into the town. After this, their first introduction as a military weapon, the carcass rockets have been used in almost every expedition, and in nearly all under the immediate inspection of their inventor. Their reputation was completely established at Copenhagen, where they did incredible execution; after the siege, they were ordered by Lord Chatham, the master-general of the ordnance, to be reported upon by a committee of field officers of artillery, who

had witnessed their effect in that bombardment, and who pronounced them to be "a powerful auxiliary to the present system of artillery." Indeed, the powers of this weapon are now established upon the best of all testimonies, the best of all criterions, the testimony of the enemy; a striking instance of which occurred at the siege of Flushing, where General Monnet, the French commandant, made a formal remonstrance to Lord Chatham respecting the use of them in that bombardment; then which no better fact need be recorded of the effect they must have produced. If such, therefore, be the acknowledged power of the weapon in such an early stage of its progress, and only when a handful, as it were, were used, merely by way of experiment, under the inventor, with not more than twenty or thirty men to assist him, what may not be expected, when regularly organized in the service, and generally combined with the other implements of bombardment?

ROCKY, composed of abounding in stone, slate, &c. as distinguished from sandy, muddy, &c.

ROD, or **POLE**, a long measure of $16\frac{1}{2}$ linear feet, or square measure of $272\frac{1}{2}$ square feet.

RODDEN CRIBS, in Agriculture, a sort of large wicker-work basket, for containing the hay or other fodder in farm yards.

ROE, the spawn or seed of fish. That of male fishes is usually distinguished by the name of soft roe, or milt, and that of the female by hard roe or spawn.

ROEMER, OLAUS, a celebrated Danish mathematician, was born in Jutland in 1644, but spent several years at Paris, during which time he discovered the progressive motion of light by observations on the eclipses of Jupiter's satellites; to him also we owe the theory of epicycloids, and their application to the teeth of wheels in machinery, which De La Hire afterwards wished to appropriate to himself.

ROESTONE, OOLITE, in Mineralogy, so called, because it is composed of small round globules, supposed to resemble the roes of fishes, imbedded in a calcareous cement. These globules vary in size from a grain of mustard to that of a pea, and are evidently the result of crystallization.

ROGATION WEEK, the week immediately preceding Whit Sunday, thus called from three fasts therein.

ROGUE, in Law, an idle and sturdy beggar, who, by ancient statutes, for the first offence was punished by whipping, and boring through the gristle of the right ear with a hot iron. For the second offence, if above the age of eighteen, he was to be put to death.

Rogue's March, in Military language, a peculiar beat of the drum, accompanied by fifes, when a soldier is drummed out of a regiment, or prostitutes are expelled a camp or garrison.

Rogue's Yarn, a name given to a rope-yarn, which is twisted in a contrary manner to the rest of a rope, and being tarred, if in a white rope, but white if in a tarred rope, is easily discovered; it is placed in the middle of the strand in all cables or cordage made for the king's service to distinguish them from the merchant's cordage.

ROHAULT, JAMES, a French Philosopher, was born in 1630; and very early became a great admirer and advocate of the philosophy of Descartes, in defence of which he wrote his "Physics," which was afterwards translated into Latin by Dr. Clark, with corrections, the best edition of which is 1718.

ROLL, in Law, signifies a schedule or parchment which may be rolled up in the hand into the form of a pipe.

ROLL, or **ROLLER**, is also a piece of wood, iron, brass, &c. of a cylindrical form, used in the construction of several machines, and in several works and manufactures.

ROLLE, MICHEL, a French mathematician, born in 1652, and died in 1685, in his 53d year.

ROLLER, in Gunnery, is a round piece of wood, about nine inches in diameter, and four feet long, used in moving mortars from one place to another when near. Rollers are very numerous, and are applied to various purposes,—in machinery, in agriculture, and in domestic life.

ROLLER, a cylindrical piece of timber fixed either horizontally or vertically in different parts of a ship, so as to revolve about an axis; it is used to prevent the cables, hawsers, and running rigging, from being chafed, by lessening the friction they would otherwise sustain.

ROLLERS, are also moveable pieces of wood of the same figure,

which are occasionally placed under boats, pieces of timber, &c. in order to move them with greater facility.

ROLLING, that motion of a body, which is caused by its rectilinear motion being resisted, by the friction of some surface or otherwise; whereby its several parts come successively in contact with that plane or surface; such is the motion of a carriage wheel upon the ground, &c. See **ROTATION**.

ROLLING, the motion by which the ship rocks from side to side like a cradle, occasioned by the agitation of the sea. Rolling is accordingly a sort of revolution about an imaginary axis passing through the centre of gravity of a ship, so that the nearer the centre of gravity is to the keel, the more violent will be the rolling motion; because the centre about which the vibrations are made, is placed so low in the bottom, that the resistance made by the keel to the volume of water which it displaces in rolling, bears very little proportion to the force of the vibration above the centre of gravity, the radius of which extends as high as the mast-heads. But if the centre of gravity is placed higher above the keel, the radius of vibration will not easily be diminished, but an additional force to oppose the motion of rolling will be communicated to that part of the ship's bottom which is below the centre of gravity. Many fatal disasters have arisen to ships from their violent rolling, as the loss of the masts, loosening the cannon, and straining the decks and sides; it is therefore particularly necessary to guard against it as much as possible, not only in the construction of the bottom, but by causing the centre of gravity of the ship to fall as near the load-water line as possible, which can only be effected by a judicious arrangement of the ballast or cargo.

ROLLING MACHINE, for making the brass mouldings in leaders, and in the brass work of grates. The invention of this machine originated in a cause, which has since operated in producing many others, namely, the reduction of prices at the peace. The usual mode of raising the brass mouldings previous to that period, was by hammering and pressing, which being very laborious as well as tedious, Mr. McKinnon turned his attention to the invention of some other mode by which the operation might be rendered more easy and less expensive. The price of the manufactured article had fallen so low, and the wages of the workmen not having suffered a corresponding depression, rendered this almost necessary; and, accordingly, after some trials, the present machine was constructed, which answers the purpose most perfectly. The invention is entirely his own; but a knowledge of its construction, (which is abundantly simple,) having been communicated to some individuals through the medium of workmen who had been with him, it is now generally known to manufacturers in the line, and we therefore consider it unnecessary to withhold it from the public.

Description of the Machine.—Fig. 1. A the bottom, and B B the sides or uprights of the frame; g g, two moveable rollers, and d d guides, of which there are two on each side of the

Fig. 2.

Fig. 1.

rollers; see Fig. 2. When the machine is to be used, it is placed on an iron stand, two feet and a half high, and fastened to the floor. The screws c c are then screwed upwards, to separate

the rollers so as to admit the flat plate of brass to be moulded. The end of the plate being then inserted between the rollers, the screws c c are screwed down, and the rollers turned by handles attached to the square projecting ends A A. By this motion, the brass will acquire the same moulding as is formed upon the rollers, of which there are a great variety of patterns. Should the moulding be not completely formed after having gone once through, it is only necessary to screw the rollers tighter together, and pass it through until the accurate form be obtained. The rollers in the drawing are used chiefly for the ornamental brass work of grates. When fenders are to be made, one of the uprights, B, at the left hand, Fig. 1, is to be removed to the end of the sole plate, to admit the fenders. The operation of making these, being in every respect the same as described above, it is unnecessary to be more minute.

ROLLING MILL, in Metallurgy, is a mill for reducing masses of iron, copper, or other metals, into even parallel bars, or thin plates. This is effected by passing the metal, whilst red hot, between two cylindrical rollers of steel, put in motion by the mill, and being so mounted in a strong metal frame that they cannot recede from each other, they can press the metal which is passed between them, and reduce it to a thickness equal to the space between their surfaces. Rolling mills have not been in general use until within about ninety years.

ROLLING Tackle, a purchase occasionally fixed on the weather quarter of a yard, in order to confine it, and prevent its chafing when a ship rolls heavily.

ROMAIN, in Agriculture, the name of a plant cultivated in the fields, and called by English farmers French vetches.

ROMAN CATHOLICS, in Church History, a name given to those Christians who believe the doctrines and submit to the discipline of the church of Rome. They are also called Papists, from *papa*, father, the pope.

ROMANCE, a fabulous relation of certain intrigues and adventures in love and gallantry, invented to entertain the frivolous and fickle among readers. Sometimes they are instructive, but more generally they are delusive, by representing as true, what has no real existence.

ROOD, a square measure, the fourth of an acre. See **MEASURE**.

ROOF. See **HOUSE**.

ROOK, in Ornithology, a well-known bird of the crow kind. Many curious particulars belong to their natural history.

ROOKERY, in rural economy, a term applied to a nursery of rooks, where they build their nests and collect in large numbers. Rookery is also applied, in cant language, to a house in which females of abandoned character associate.

ROOM, at Sea, a name given to some particular apartment in a ship, as, the *Cook Room*. See the article **GALLERY**. The *Bread Room*, is in the aftermost part of the hold, being partitioned off and properly lined, to receive the bread, and keep it dry. *Gua Room*; *Light Room*. *Steward Room*, the apartment where the steward weighs, measures, and serves out the provisions to the ship's company; it is usually situated on the orlop deck, adjoining to the bread-room. *Sail Rooms*, are places on the orlop deck, enclosed for the reception of the sails: they are distinguished according to their relative situation, as, the fore-sail room, the after sail-room.

Spirit Room, a space in the after part of a ship's hold, set apart for the reception of wine, brandy, &c.

Ward Room, a room over the gun-room in ships of war, where the lieutenants and other principal officers sleep and mess.

ROOT, in Arithmetic and Algebra, denotes a quantity, which being multiplied a certain number of times into itself, produces another number, called a power, and of which power the original quantity is called the root. Roots are distinguished into square roots, cube roots, biquadratic roots, &c. or into 2d, 3d, 4th, 5th, &c. roots, which depend upon the number of multiplications necessary to generate the proposed power. If one multiplication only is necessary, or if two equal factors are multiplied together, it is called the square or second root; if three, the cube or third root; if four, the biquadratic or fourth root, &c.; thus 8 is the square root of 64; 4 is the cube root of 64; 2 is the sixth root of 64, &c. &c. For the extraction of the roots of numbers, see **EXTRACTION**.

Root, in Mathematics, a quantity considered as the basis or foundation of higher power; or one which, being multiplied

into itself any number of times, produces a square, cubic, biquadratic, &c. quantity; called the second, third, fourth, &c. power of the root, or quantity so multiplied into itself.

Root, in vegetable physiology, is an important part of the vegetable body, being the basis of the whole, and what is first produced from the seed when evolved by the process of germination. Its uses are to fix the plant in the ground, and to derive nourishment for its support.

ROPES, are a general name given to all sorts of cordage above one inch in circumference, used in rigging a ship. Ropes are of two descriptions, viz. *Cable-laid*, which are composed of nine strands, the three great strands containing each three small strands; and *Hawse-laid*, which are made with three strands, each composed of a certain number of rope-yarns in proportion to its required thickness.

Rope Yarn, the smallest and simplest part of any rope, being one of the threads of which a strand is composed, so that the size of the latter, and of the rope in which it is twisted, are determined by the number of rope-yarns.

ROQUET, in Zoölogy, the name of a species of American lizard, small in size, of a reddish brown colour, variegated with black and yellow spots. Its eyes are particularly vivid and sparkling.

ROSA, the *Rose*, a fragrant flower, too well known to require any description in this work. The species are exceedingly numerous.

ROSADE, a kind of liquor prepared of pounded almonds and milk, mixed with clarified sugar.

ROSARY, in the Romish church, is a chaplet consisting of five or fifteen decades of beads, to direct the recitation of so many Ave Maria's in honour of the Virgin. It also denotes a particular mass or form of devotion addressed to the Virgin, to which the chaplet of that name is accommodated.

ROSE ENGINE, a machine used for turning articles in wood like a common lathe, with additional properties, by which the surface of the wood that has been turned can afterwards be engraved with a great variety of patterns of curved lines. These, in general, are denominated from the French rosette, from a distant resemblance which they have to a full-blown rose, and hence, the machine is called a rose engine. Its construction is remarkably curious.

ROSEWOOD, *How to make Imitations of*.—Brush the wood over with a strong decoction of logwood, while hot; repeat this process three or four times; put a quantity of iron filings amongst vinegar; then, with a flat open brush, made with a piece of cane, bruised at the end or split with a knife, apply the solution of iron filings and vinegar to the wood, in such a manner as to produce the fibres of the wood required. After it is dry, the wood must be polished with turpentine and bees-wax.

ROSICRUSIANS, a sect of hermetical philosophers, first noticed in Germany in the fourteenth century. An affected secrecy gave them fame, especially as they pretended to have discovered the philosopher's stone. But when it was proved they had nothing to conceal, they sunk into neglect, and finally into contempt.

ROSIN. See **RESIN**.

ROSMARUS, the name of an animal; sometimes called the *Sea Horse*, but more commonly the *Mase*.

ROSMARINUS, **ROSEMARY**, a genus of the monogynia order, in the diandria class of plants, and in the natural method ranking under the 42d order, verticillata. The corolla is unequal, with its upper lip bipartite; the filaments are long, curved, and simple, each having a small dent. There are two species.

ROSOMACHA, in Zoölogy, a name given by the Russians to the glutton. Claus says, they are taken by the hunters chiefly for their skins, which are much esteemed by persons of fortune, for robes, the fur being naturally variegated with bright colours resembling flowers.

ROSTRA, in Antiquity, a part of the Roman Forum, in which orations, pleadings, funeral harangues, &c. were delivered. The Rostrum, taken as a sort of chapel out of the Forum, was furnished with an eminence on which the orators stood to speak, and to this elevation the name was more particularly applied. Hence, the term Rostrum has been transferred to pulpits, platforms, and stages, in the present day.

ROSTRUM, in Ornithology, literally denotes the beak of a

bird, and is applied to the hard and horny edges of the bill, which answer to the mandible in quadrupeds. Hence the word is figuratively applied to the prow or head of a ship. *Rostrum* is also used to designate an instrument with which paper is ruled for musical compositions. *Rostrum*, in Chemistry, signifies the nose or beak of the common alembic, which conveys the liquor distilled into the receiver. In Surgery, *Rostrum* is a sort of crooked scissors used for the dilation of wounds. It likewise means the piece of flesh situated between the margins of a hare-lip. In Botany, *Rostrum* expresses the beak of a seed, or rather the elongation of the apex of a naked seed.

ROT, in rural economy, a sort of putrid decay taking place gradually, in various substances, either from the effects of moisture, or other causes.

ROT, is also a disease incident to sheep and other animals, in which the liver and lungs are affected, and a tendency to dropy is produced. It is chiefly connected with moisture, but its causes have not yet been satisfactorily explored.

ROT, Dry. See **DRY ROT**.

ROT, in hops, is a disease in the crops of this valuable article, very similar to mouldiness.

ROTA, in Mechanics. See **WHEEL**.

ROTA Aristotelica, or *Aristotle's Wheel*, denotes a problem in mechanics proposed by Aristotle concerning the motion of a coach wheel; viz. that the nave of a wheel describes by its motion, (supposing it to roll along a plane,) a line of the same length as the circumference by its motion on the ground; which was long considered paradoxical, nor was it clearly understood till M. Meyran, a Frenchman, sent a satisfactory solution of it to the Academy of Sciences, the principle of which is, that each point of the circumference of the nave, as it approaches the plane, is drawn forward over a space greater than itself, whereas every point and part of the circumference of the wheel passes over a space exactly equal to itself.

ROTATION, the motion of the different parts of a solid body about an axis called the *axis of rotation*, being distinguished from the progressive motion of a body about some distant point or centre; thus the diurnal motion of the earth is a motion of rotation, but its annual motion one of revolution. When a solid body turns round an axis, retaining its shape and dimensions unaltered, every particle is actually describing a circle round this axis, which axis passes through the centre of the circle, and is perpendicular to its plane. Moreover, in any instant of the motion the particle is moving at right angles with the radius vector, or line joining it with its centre of rotation; therefore, in order to ascertain the direction of any particle, we may draw a line from that particle perpendicular to the axis of rotation. This line will be in the plane of the circle of rotation of that particle, and will be its radius vector, and a line drawn from the particle perpendicular to its radius vector, will be a tangent to the circle of rotation, and will represent the direction of the motion of this particle. The whole body being supposed to turn together, it is evident, that when it has made one complete rotation, each point has described the circumference of a circle, and the whole paths of the different particles will be in the ratio of these circumferences, and therefore of their radii; and this is also true of any portion of such circumferences, that is, the velocities of the different particles are proportional to their radii vectores, or to their distances from the axis of rotation. And all these motions are in parallel planes, to which the axis of rotation is perpendicular. Hence it follows, that when we compare the rotation of different bodies in respect of velocity, it is evident that it cannot be done by directly comparing the velocity of any particle in one of the bodies with that of any particle of the other; for as all the particles of each have different velocities, this comparison can establish no ratio. But we may familiarly compare such motions by the number of complete turns which they make in any equal portions of time. Therefore as the length or number of feet described by a body in rectilinear motion is a proper measure of its progressive velocity, so the angle described by any particle of a whirling body is a proper measure of its velocity of rotation; and in this manner may the rotation of two or more bodies be compared, and

this velocity is with propriety called the angular velocity. In what is stated above, we have had principally in view a fixed and permanent axis of rotation, the body not being supposed at liberty to revolve about any other; but it is obvious that if any force is impressed upon a body, or system of bodies, in free space, (unless that force be exerted in a direction passing through the centre of gravity of the system) a rotatory motion will ensue about an axis passing through the centre of gravity of the system; and the centre about which this motion is performed, is called the *centre of spontaneous rotation*. A body may begin to revolve on any line as an axis that passes through the centre of gravity, but it will not continue to revolve permanently about that axis unless the opposite centrifugal forces exactly balance each other. Thus a homogeneous sphere may revolve permanently on any diameter, because the opposite parts of the solid, being in every direction equal and similar, the opposite centrifugal forces must be equal; so that no force has a tendency to change the position of the axis. Hence also a homogeneous cylinder may revolve permanently about the line which is its geometric axis; as it may also about any line that bisects that axis at right angles, but it can revolve permanently about no other line, because then the centrifugal forces could not be equal; and the same is true to any solid of rotation.

In every body, however irregular, there are three permanent axes of rotation, at right angles to each other, on any one of which when the body revolves, the opposite centrifugal force exactly balances, and therefore the rotation becomes permanent. These three axes have also this remarkable property, that the momentum of inertia, with respect to any of them, is either a maximum or a minimum; that is, either greater or less than if the body revolved about any other axis. This curious theorem was first proposed by Segner in 1755, and first demonstrated by Albert Euler, in a memoir presented to the academy of sciences at Paris in 1766.

At present we have considered those cases of rotation that are produced by a force impressed upon a body, either as supported on a fixed axis, about which, therefore, that system must necessarily revolve; or as in free space, in which case the system acquires a spontaneous centre of rotation, and finally a permanent axis of rotation; but there are other circumstances which will produce a rotatory motion, that are not included in either of the above, but which it will be proper to mention before we conclude this article, such are those which arise from a body descending down an inclined plane, having a ribbon or cord wound about it, one end of which is fixed at the upper part of the plane, which by preventing the body sliding freely, causes a rotatory motion: the same effect also follows from the friction of the body against the plane; and the same may be imagined when there is no plane but the body left to fall freely, except so far as the cord wound about it shall produce a rotatory motion in its descent. We shall not attempt the investigation of these cases, but merely state the results that have been obtained, and must refer the reader for the former to the several treatises on dynamics referred to in various parts of this volume, and to the articles **DYNAMICS** and **MECHANICS**.

Let a body have a cord wound about it, either at its circumference or any other part, as BC, having one end fixed at a point above, as at A; then if the body be left to descend by the action of gravity, it will acquire a motion of rotation by the unwinding of the cord; and the space actually descended by the body in this case, will be to the space descended in the same time when falling freely, as CG to CO; O and G representing the centres of oscillation and gyration, when the point of suspension is at C: and the weight of the body will be to the tension of the cord, as CO to CG; and the same ratios have place when the body descends down an inclined plane: the forces which generate the motion being both decreased in the same ratio. The force by which spheres, cylinders, &c. are caused to revolve as they move down an inclined plane (instead of sliding), is the adhesion of their surfaces, occasioned by their pressure against

the plane; this pressure is part of the weight of the body, for this weight being resolved into its component parts, one in the direction of the plane, the other perpendicular to it; the latter is the force of the pressure; and which while the same body rolls down the plane, will be expressed by the cosine of the plane's elevation. Hence, since the cosine decreases, while the arc or angle of elevation arrives at a certain magnitude, the adhesion may become less than what is necessary to make the circumference of a body revolve fast enough, and in this case it will proceed partly by sliding and partly by rolling; but the angle at which this circumstance takes place, will evidently depend upon the degree of adhesion between the surfaces of the body and plane. This, however, will never happen, if the rotation is produced by the unwinding of a ribbon, and it is on this latter supposition that the following particular cases are deduced. Let W be the weight of the body, s the space descended by a heavy body, falling freely, or sliding freely down a plane, then the spaces described by rotation in the same time, by the following bodies, will be in these proportions.

1. A hollow cylinder, or cylindrical surface $S = \frac{1}{2}s$, tension $= \frac{1}{2}W$. 2. A solid cylinder $S = \frac{2}{3}s$, tension $= \frac{1}{3}W$. 3. A spheric surface $S = \frac{2}{3}s$, tension $= \frac{1}{3}W$. 4. A solid sphere $S = \frac{2}{5}s$, tension $= \frac{1}{5}W$.

ROTATORY MOTION, when produced by a reciprocating motion, requires some contrivance to render it uniform, or nearly so. The usual method of equalizing is, by attaching a fly wheel to some part of the machinery; but Mr. Arthur Woolf has invented an apparatus to be substituted for the fly in steam-engines, which possesses the advantage of equalizing the motion, with the property of being stopped, and set to work at any part of the stroke.

In fig. 1, A represents part of the engine beam; B, the connecting rod; C, the crank arm; D, a cog wheel, working into another cog wheel E, of half the size; F, a crank arm on the shaft of the small wheel; G, a cylinder closed at bottom, in which a solid or unperforated piston moves, leaving a vacuum beneath. This acts simply instead of a weight on the crank F, by the constant pressure of the atmosphere; and the diameter of the piston must be such as nearly to equal one-third of the power of the engine.

In fig. 2, the outer circle is the line described by the crank; the circumference of the inner circle is equal to twice the diameter of the outer, and the square has the same circumference: this last exhibits the inequality still remaining, which by this method is reduced to about one-fifth; but by the assistance of a small fly on the second motion, the effect will become nearly the same as that of a rotative engine, with the advantages here mentioned. The same motion may be applied to a pump, but in this case the two cranks must be horizontal at the same time.

ROTONDO, or **ROTUNDO**, in Architecture, an appellation given to any building that is round both within and without, whether it is a church, a saloon, or the like.

ROTTEN STONE, a decomposed stone used for polishing.

ROUBBIE, a coin of Turkey, value 1s. 5jd. sterling.

ROUCOU, otherwise called **ANNOTTO**, is a red dye formed in masses from the pellicles of the seeds of an American tree. That which we commonly have is moderately hard and dry, of a brown colour on the outside, and of a dull red within. Labat informs us, that the Indians prepare a dye of this article far superior to that which we have. It is of a bright shining red colour, almost equal to carmine.

ROUCEN, in Agriculture, a term that signifies aftergrass, or the hay made from it.

ROUGH CAST WASH, in rural economy, is a sort of liquid wash laid over the surfaces of outside walls, or buildings, to preserve and ornament them. It consists of four parts of pounded lime, three of sand, two of pounded wood ashes, and one of the scoria of iron, mixed intimately together, and made sufficiently thin to be applied by a brush. When dry, it gives the wall the appearance of new Portland stone, and affords an excellent protection against the severity of the weather.

ROUGH TREE, a name given in merchant ships to any mast, yard, or boom, placed as a rail or fence above the ship's side, from the quarter deck to the fore-castle; it is, however, with more propriety applied to any mast, &c. which remaining rough and unfinished, is placed in that situation.

ROUND, in a Military sense, signifies a walk which some officer, attended by a party of soldiers, takes in a fortified place around the ramparts, in the night-time, in order to see that the sentries are watchful, and that every thing is in order.

ROUND HOUSE, a name given in East Indiamen, and other large merchant ships, to a cabin or apartment built on the after part of the quarter deck; and having the poop for its roof, this apartment is frequently called the coach, in ships of war.

ROUND House, is also a name given on board ships of war to certain necessities built near the head, for the use of the mates, midshipmen, and warrant officers.

ROUNDELAY, an antiquated kind of poem, of peculiar metre, at present but little known in this country.

ROUNDING, old ropes wound firmly and closely about that part of a cable which lies in the hawse, or athwart the stem &c. It is used to prevent the cable from being chafed.

ROUNDING IN, generally implies the act of pulling upon any slack rope which passes through one or more blocks in a direction nearly horizontal, and is particularly applied to the braces as, "Round in the weather braces." It is apparently derived from the circular motion of the rope about the sheave or pulley through which it passes. *Rounding up*, is used nearly in the same sense, only that it is expressed of a tackle which hangs in a perpendicular direction, without sustaining or hoisting any weighty body, and is opposed to over-hauling. *Round Turn*, the situation of the two cables of a ship, which when moved has swung the wrong way three times successively. *Round Turn*, is also the passing a rope once round a timber head, &c. in order to hold on.

ROUSE, To, is to pull together upon a cable, &c. without the assistance of tackles, capstans, or other mechanical powers.

ROUT, in Law, is an assemblage of more than three persons going forcibly to commit an unlawful act, even though they do not actually execute their intentions. To make advances towards it, is a rout; to execute their designs, is a riot.

ROVER, a pirate or freebooter.

ROW CULTURE, in Agriculture, is that method in which the crops are sown in drills, and afterwards cultivated according to that system.

ROW, To, to impel a boat or vessel along the surface of the water by oars, which are managed in a direction nearly horizontal.

Row Dry, the order to those who row, not to splash water into the boat with their oars.

Row Locks, those parts of a gunwale, or upper edge of a boat's side, whereon the oars rest in the exercise of rowing.

Row Galley, a long, low, flat-built vessel, sometimes furnished with a deck, and navigated with sails and oars particularly in the Mediterranean.

ROWED of All, the order for the rowers to cease and to lay their oars in the boat.

ROWERS, the persons by whom the oars are managed.

Row Ports, little square holes cut in the sides of small vessels of war, parallel to the surface of the water, for the purpose of rowing them in a calm.

ROWETY WOOL, a term applied to the young wool of some sheep, which rises below the old fleece.

ROWLEY RAG, in Mineralogy, a basaltic stone from Rowley, near Dudley, in Staffordshire. It is used for polishing some of the manufactures of Birmingham, and has been strongly recommended for grinding the specula of reflecting telescopes.

ROWING, JOHN, an ingenious English mathematician, was born about the year 1700, and died in 1771.

ROYAL, the name of a sail spread immediately above the top-gallant sail, to whose yard-arms the lower corners of it are attached: it is sometimes termed top-gallant royal, and is never used but in fine weather.

ROYAL EXCHANGE, the bourse or meeting-place of the merchants in London. It was built in 1566, at the charge of Sir Thomas Gresham, and in a solemn manner by herald, with sound of trumpet, in the presence of Queen Elizabeth, proclaimed "The Royal Exchange." Prior to this time the merchants met in Lombard-street. In the great fire in 1666, it was totally consumed, but was soon raised again with still greater magnificence, at an expense of £50,000.

ROYAL Society, in London, is an academy, or body of persons eminent for learning and scientific knowledge, instituted by Charles II. for the promoting of natural knowledge.

RUBIFYING, in Chemistry, the act of turning any thing red by the force of fire. Thus, red arsenic is common white arsenic rubified by a mixture of sulphur and copper.

RUBIGO, a disease in corn when growing, commonly called mildew. For this, various causes have been assigned, but the real source of this agricultural malady still remains partially unexplored.

RUBIN of ANTIMONY, in Chemistry, is a kind of liver of antimony, made with equal parts of crude antimony and nitre detonated together, to which is afterwards added an equal quantity of common salt.

RUBLE, a Russian coin, those of 1764, value 3s. 3d.; and of 1801, value 2s. 9½d. sterling.

RUBRIC, in the Canon Law, signifies a title or article in certain ancient law books; thus called because written, as the titles of the chapters of our ancient Bibles are, in red letters. Rubrics also denote the rules and directions given at the beginning and in the course of the liturgy, for the order and manner in which the several parts of the office are to be performed. There are general rubrics, special rubrics, a rubric for the communion, &c. In the Romish missal and breviary are rubrics for matins, for lauds, for translations, beatifications, &c.

RUBUS, the *Raspberry*, a genus of the polygamia order, in the icosandria class of plants; and in the natural order ranking under the 35th order, senticosæ. The calix is quinquefid, the petals five: the berry consisting of monospermous acini, or pulpy grains. There are 32 species.

RUBY, a genus of precious stones of various colours; as 1. Of a deep red colour, inclining a little to purple; the carbuncle of Pliny. 2. The spinell, of the colour of a bright corn poppy flower. 3. The balass, or pale red, inclining to violet. 4. The rubi cell, of a reddish yellow.

RUCTATION, in Medicine, belching, an involuntary discharge of flatus from the stomach. This is a symptom of indigestion. Persons liable to this complaint should carefully avoid fermentive food, in which class all vegetables are included.

RUDDER, in Navigation, a piece of timber turning on hinges in the stern of the ship, and which, opposing sometimes one side to the water and sometimes another, turns or directs the vessel this way or that. See **HELM**.

RUDDOCK, the name of a well-known bird, *Robin red breast*.

RUDIMENTS, the first principles or grounds of any art or science, sometimes called elements.

RUDOLPHINE TABLES, a celebrated set of astronomical tables published by Kepler, and thus entitled in honour of the emperor, Rudolph, or Rudolphus.

RUE, in Medicine, a plant well known, the leaves of which have a strong ungrateful odour, and a bitter, hot, penetrating taste. If much handled, they are so acrid as to irritate and inflame the skin. In the *Materia Medica* rue is of great value, being used in many ways, and applied to various purposes.

RUININE OIL, the oil of the Palma Christi, which is very common in the West Indies, and is used by the common people in lamps. It is delicate, sweet, and transparent; its leaves are one of the grand remedies among the negroes; and when bruised and applied to the head, they are thought to be an infallible cure for the head-ache.

RUINS, a term more particularly applied to magnificent buildings fallen to decay; such as Babylon, Persepolis, &c.

RULE, or **RULER**, an instrument of wood or metal with several lines delineated on it, of great use in practical mensuration.

RULE OF THREE, in Arithmetic, called by some authors the *Golden Rule*, is an appellation of the doctrine of proportion to arithmetical purposes, and is divided into two cases, *simple* and *compound*; now frequently termed *Simple* and *Compound Proportion*.

Simple Rule of Three, or *Simple Proportion*, is, when from three given quantities, a fourth is required to be found, that shall have the same proportion to the given quantity of the same name, as one of the other quantities has to that of the same name with itself. This rule is, by some authors divided into two cases; viz. *The Rule of Three Direct*, and *The Rule of Three Inverse*; but this distinction is unnecessary, and the two cases are now generally given under one head by all our best modern authors; but as they are still retained by others, it will not be amiss to point out the distinction.

The Rule of Three Direct, is when more requires more, or less requires less, as in this example: If 3 men will perform a piece of work, as for instance, dig a trench 48 yards long in a certain time; how many yards will 12 men dig in the same time? where it is obvious, that the more men there are employed, the more work will they perform, and therefore, in this instance, more requires more. Again, if 6 men dig 48 yards in a given time, how much will 3 men dig in the same time? Here less requires less, for the less men there are employed, the less will be the work that is performed by them; and all questions that are in this class are said to be in the Rule of Three Direct.

The Rule of Three Inverse, is, when more requires less, or less requires more. As in this, if 6 men dig a certain quantity of trench in 14 hours; how many hours will it require for 12 men to dig the same quantity? Or thus, if 6 men perform a piece of work in 7 hours; how long will three men be in performing the same work? These cases are both in the Inverse Rule, for in the first more requires less, that is, 12 men being more than 6 they will require less time to perform the same work; and in the latter, the number of men being less, they will require a longer time. All questions of this class are said to be in the Rule of Three Inverse. These two cases, however, as we before observed, may be classed under one general rule, as follows:—

Rule.—Of the three given terms, set down that which is of the same kind with the answer towards the right hand; and then consider, from the nature of the question, whether the answer will be more or less than this term. Then if the answer is to be greater, place the less of the other two terms on the left, and the remaining term in the middle; but if it is to be less, place the greater of these two terms on the left, and the less in the middle; and in both cases, multiply the second and third terms together, and divide the product by the first term for the answer, which will always be of the same denomination as the third term. **Note 1.** If the first and second terms consist of different denominations, reduce them both to the same; and if the third term be a compound number, it is generally more convenient to reduce it to the lowest denomination contained in it.—**Note 2.** The same rule is applicable whether the given quantities to be integral, fractional, or decimal.

Central Rule. See **CENTRAL RULE**.

Sliding Rule, a mathematical instrument serving to perform computations in gauging, measuring, &c. without the use of compasses, merely by the sliding of the parts of the instrument one by another, the lines and divisions of which give the answer or amount by inspection. This instrument is variously contrived, and applied to different authors, particularly Gunter, Partridge, Hunt, Everard, and Coggeshall, but the more usual and useful ones are those of the two latter.

Everard's Sliding Rule, is chiefly used in cask gauging. It is commonly made of box, 12 inches long, 1 inch broad, and $\frac{1}{4}$ of an inch thick. It consists of three parts, viz. the stock just mentioned, and two thin slips of the same length, sliding in small grooves in two opposite sides of the stock; consequently when both these pieces are drawn out to their full extent, the instrument is 3 feet long. On the first broad face of the instrument are four logarithmic lines in numbers, for the properties, &c. of which, see **GUNTER'S LINE**. The first marked A, consisting of two radii 1, 2, 3, 4, 5, 6, 7, 8, 9, 1; and then 2, 3, 4, 5, &c. to 10. On this line are four brass centre pins, two in each radius: one in each of them being marked M B. for malt bushel, is set at 2150.42, the number of cubic inches in a

malt bushel; the other two are marked with A, for ale gallon, at 282, the number of cubic inches in an ale gallon. The 2d and 3d lines of numbers are on the sliding pieces, and are exactly the same with the first; but they are distinguished by the letter B. In the first radius is a dot marked S 1, at .707, the side of a square inscribed in a circle whose diameter is 1. Another dot marked Sc. stands at .886, the side of a square equal to the area of the same circle. A third dot, marked W, is at 231, the cubic inches in a wine gallon. And a fourth marked C, at 314, the circumference of the circle, whose diameter is 1. The fourth line of numbers, marked M D, to signify malt depth, is a broken line of two radii, numbered 2, 10, 9, 8, 7, 6, 5, 4, 3, 2, 1, 9, 8, 7, &c.; the number 1 being set directly against M B on the first radius.

On the second broad face marked *c d*, are several lines; as first a line marked D, and numbered 1, 2, 3, &c. to 10. On this line are four centre pins, the first marked W G, for wine gage, is at 17.15, the gage point for wine gallons being the diameter of a cylinder whose height is one inch, and content 231 cubic inches, or a wine gallon. The second centre pin marked A G, for ale gage, is at 18.95, the like diameter for an ale gallon. The third mark M S, for malt square, is at 46.3, the square root of 2150.42, or the side of a square whose content is equal to the number of inches in a solid bushel. And the fourth marked M R, for malt round, is at 52.32, the diameter of a cylinder or bushel, the area of whose base is the same 2150.42, the inches in a bushel. 2dly. Two lines of numbers upon the sliding piece, on the other side marked C. On these are two dots, the one marked c, at .0795, the area of a circle whose circumference is 1; and the other marked d, at .785, the area of the circle whose diameter is 1. 3dly. Two lines of segments, each numbered 1, 2, 3, to 100, the first for finding the ullage of a cask, taken as the middle frustum of a spheroid, lying with its axis parallel to the horizon; and the other for finding the ullage of a cask standing. Again, on one of the narrow sides noted c, are first a line of inches, numbered 1, 2, 3, &c. to 12, each subdivided into 10 equal parts. 2dly. A line by which, with that of inches, we find a mean diameter for a cask in the figure of the middle frustum of a spheroid; it is marked spheroid, and numbered 1, 2, 3, &c. to 7. 3dly. A line for finding the mean diameter of a cask, in the form of the middle frustum of a parabolic spindle, which gaugers call the second variety of casks; it is therefore marked second variety, and is numbered 1, 2, 3, &c. 4thly. A line by which is found the mean diameter of a cask of the third variety, consisting of the frustums of two parabolic conoids, abutting on a common base, it is therefore marked third variety, and is numbered 1, 2, 3, &c. On the other narrow face marked f, are, 1st, a line divided into one hundred equal parts, marked F M. 2ndly. A line of inches, like that before mentioned, marked I M. 3dly. A line for finding the mean diameter of the fourth variety of casks, which is formed of the frustums of two cones, abutting on a common base. It is numbered 1, 2, 3, &c. and marked F C, for frustum of a cone. On the back side of the two sliding pieces is a line of inches, from 12 to 36, for the whole extent of the 3 feet, when the pieces are put endways; and against that, the correspondent gallons and 100th parts that any small tub or the like open vessel will contain at 1 inch deep. For the various uses of this instrument, see the authors mentioned above, and most writers on gauging.

Coggeshall's Sliding Rule, is chiefly used in measuring the superficies and solidity of timber, masonry, brick-work, &c.

This consists of two parts, each a foot long, which are united together in various ways. Sometimes they are made to slide by one another like glaziers' rulers: sometimes a groove is made in the side of a common two-foot rule, and a thin sliding piece on one side, and Coggeshall's lines added on that side; thus forming the common or carpenter's rule; and sometimes one of the two rulers is made to slide in a groove made in the side of the other. On the sliding side of the rule are four lines of numbers, three of which are double, that is, are lines of two radii, and the fourth is a single broken line of numbers. The first three marked A, B, C, are figured 1, 2, 3, &c. to 9; then 1, 2, 3, &c. to 10; the construction and use of them being the same as those on Everard's sliding rule. The single line called the girt line, and marked D, whose radius is equal to two radii of any of the other lines, is broken for the easier measuring of

timber, and figured 4, 5, 6, 7, 8, 9, 10, 20, 30, &c. From 4 to 5 it is divided into 10 parts, and each 10th subdivided into 2, and so on from 5 to 10, &c. On the back side of the rule, are, 1st. a line of inch measure, from 1 to 12, each inch being divided and subdivided. 2ndly. A line of foot measure consisting of one foot divided into 100 equal parts, and figured 10, 20, 30, &c. The back side of the sliding piece is divided into inches, halves, &c. and figured from 12 to 24; so that when the slide is out, there may be a measure of 2 feet. In the carpenter's rule the inch measure is on one side, continually all the way from 1 to 24, when the rule is unfolded, and subdivided into 8th or half quarters; on this side are also some diagonal scales of equal parts. And upon the edge, the whole length of two feet is divided into 200 equal parts or 100ths of a foot.

RULES of COURT, in Law, are certain orders made from time to time, in the courts of law, which attorneys are bound to observe in order to prevent confusion; and both the plaintiff and defendant are, at their peril also bound to pay obedience to rules made in court relating to the cause depending between them.

RUM, a species of vinous spirit, distilled from sugar-canes.

RUMEN, in comparative Anatomy, the paunch or first stomach of such animals as chew the cud, thence called ruminant animals.

RUMI, in the *Materia Medica*, a name given to mastic of the finer kind.

RUMINANT, in Natural History, is applied to an animal that chews over again what it has eaten before: this is popularly called, "chewing the cud." *Ruminatio*, in Medicine, and *Rumination*, in Natural Philosophy, are terms of the same family, and of kindred import.

RUN, the foremost part of a ship's bottom, where it grows extremely narrow as the floor approaches the stern-post. *Run*, is also the distance sailed by a ship. *Run*, is also used among sailors, for the agreement to work a single passage from one place to another; as, from Jamaica to England, &c. *To Run down a Coast*, is to sail along by it. *To Run down a Vessel*, is to pass over her by running against her end-on, so as to sink her. *To Run out the Guns*, is, by means of the tackles, to force their muzzles out of the port-holes. *To Run out a Warp*, is to carry the end of a hawser out from the ship in a boat, and fasten it to some distant place to remove the ship towards that place, or to keep her steady whilst her anchors are lifted, &c. *To let Run a Rope*, is to let it quite loose. *A Run Man*, implies a deserter from a ship of war.

RUNDLET, or **RUNLET**, a small vessel containing an uncertain quantity of any liquor, from three to twenty gallons.

RUNG HEADS, a name sometimes given by shipwrights to the upper ends of the floor-timbers, which are otherwise more properly called floor-heads.

RUNIC, a term applied to the language and letters of the ancient Goths, Danes, and other northern nations. Many inscriptions in Runic characters are to be found in this country in old churches, and on monumental stones.

RUNIC Shafts, were a kind of calendars used in the north of Europe, marked out by lines upon short pieces of boards or smooth sticks, some of which bear the marks of great antiquity.

RUNNER, a thick rope used to increase the mechanical power of a tackle. The runner passes through a large block, and has usually a hook attached to one of its ends, and one of the tackle blocks to the other: in applying it, the hook of the runner, as well as the lower block of the tackle, is fixed to the object intended to be removed.

RUNNING FIGHT, a battle in which the enemy endeavours to escape, while the victor continues to pursue within gun-shot.

RUNNING Rigg, all that part of a ship's rigging which passes through blocks, &c. and is used in contradistinction to standing rigging. *The Running part of a Tackle*, is synonymous with the Fall, and is that part on which the power is applied to produce the intended effect.

RUPEE, a coin of different parts of the East Indies, of the sterling value of 2s. or a little more or less.

RUPERT'S Drops, a sort of glass-drops with long and slender tails, which burst to pieces on the breaking off of those tails in any part, said to have been invented by Prince Rupert, and therefore called after his name. This surprising phenomenon is supposed to rise from hence, that while the glass is in

fusion, or in a melted state, the particles of it are in a state of repulsion; but being dropped into cold water, it so condenses the particles in the external parts of their superficies, that they are easily reduced within the power of each other's attraction, and by that means they form a sort of hard case, which keeps confined the before-mentioned particles in their repulsive state, but when this outer case is broken, by breaking off the tail of the drop, the said confined particles have then a liberty to exert their force, which they do by bursting the body of the drop, and reducing it to a very peculiar form of powder.

RUPELLENSIO SAL, *Rochelle Salt*, a name given to a peculiar kind of salt invented by an apothecary of Rochelle, and much esteemed as a valuable medicine. Its composition was, for a long time, kept a profound secret, but it is now well known to most chemists.

RURAL ECONOMY, is a term which comprehends whatever tends to the improvement of land for the purposes of grazing or agriculture, either by renovating the soil by manure, the arrangement of crops, or the management of the produce.

RUSH. See **JUNCUS**.

RUSH, *Sumach*, a genus of the trigynia order, and in the pentandria class of plants, and in the natural method ranking under the 43d order, *dumosæ*.

RUSMA, a mineral substance, which, mixed with quicklime, takes off the hair. It was well known to the Egyptians and the Greeks.

RUSPONO, a coin of Tuscany value £1. 8s. 6d. sterling.

RUST, in Corn. See **RUBIGO**.

RUST, in Metal, the partial decomposition of iron and steel: all metallic bodies are liable to rust, even gold is not excepted in some situations. Water is the great agent in producing rust; and when air is assigned as its cause, the aqueous particles it contains is the efficient instrument. Oil, and fat substances, will best preserve metal from corrosion.

RUSTIC, that which is unpolished, partaking more of the simplicities of nature than the refinements of art. The term is applied to men, to their employment, their habitations, and the works they perform.

RUT, in rural economy, a track or narrow opening formed in a road or field by the wheel of a cart, or other carriage, when the rim is narrow.

RUTA BAGA, a plant of the turnip kind, that has lately been introduced into this country from Sweden, and is now cultivated with great success. It opportunely comes into use between the turnip and the grass seasons, on which account its value is considerable. Cattle, sheep, and hogs, eat it with great avidity.

RUTA, *Rue*, a genus of the monogynia order, in the decandria class of plants; and in the natural method ranking under the 26th order, *multisiliquæ*. The calyx is quinquepartite; the petals concave; the receptacle surrounded with ten melliferous pores; the capsule is lobed. In some flowers, a fifth part of the number is excluded. There are seven species.

RUTHERFORD, WILLIAM, an English philosopher, was born in 1712, and died in 1771. He is principally distinguished by "A System of Natural Philosophy," published in 1748.

RUTHILA, an ore found in Hungary, Italy, and France. It is generally crystallized.

RUTILE, an oxide of *titanium*. It is of a dark blue red colour, inclining to brown, with a degree of metallic splendour. The longitudinal fracture is foliated, the cross fracture conchoidal and unequal. It is opaque, or slightly translucent, and sometimes sufficiently hard to scratch quartz.

RUTULUS, in Roman History, the barrier of the caves, or place where the wild beasts used in amphitheatrical sports were confined. It was made of iron bars, which turned upon hinges, and flew open when required with great swiftness.

RYE, a species of grain much cultivated in some of the northern districts of England. It approaches nearer to wheat than any other grain now in cultivation. There are several varieties. In many places it is used for bread, but unadmixed with wheat, it is dry and poor. By gingerbread bakers much rye is consumed, but the distilleries absorb the greater quantity.

RYELAND SHEEP, a breed of fine-woolled sheep, originally reared to the greatest perfection in a district of Herefordshire, called the Ryelands, from which the name has been derived.

S.

S, the eighteenth letter of our alphabet: in abbreviations, stands for societas or socius; as R. S. S. for regis societatis socius, i. e. fellow of the Royal Society. In medicinal prescriptions, S. A. signifies secundum artem, i. e. according to the rules of art; and in the notes of the ancients, S. stands for sextas; S P. for spurius; S. C. for senatus consultum; S. P. Q. R. for senatus populusque Romanus; S. S. for stratum super stratum, i. e. one layer above another alternately; S. V. B. E. E. Q. V. for, si vales bene est, ego quoque valeo; a form used in Cicero's time, in the beginning of letters. Used as a numeral, S. anciently denoted seven; in the Italian music, S. signifies solo; and in books of navigation, S. stands for south; S. E. for south-east; S. W. for south-west; S. S. E. for south-south-east, &c.

SABAISM, supposed to be the first system of idolatry that ever appeared in the world. It prevailed much in the days of Moses, and is still retained in the East. Sabaism consists of the worship of the stars, or, as the scriptures term it, "the host of heaven."

SABBATARIANS, a sect of Christians, who observe the Jewish or Saturday Sabbath.

SABBATH, the seventh day of the week, held sacred among the Jews, to commemorate the completion of creation. The word is pure Hebrew, and signifies cessation or rest. Philo calls it the world's birth-day. Under the Christian system, it has been transferred to the first day of the week, to commemorate the resurrection of Christ.

SABBATH Day's Journey, about two-thirds of an English mile.

SABELLIANS, a Christian sect, who reduced the three persons in the Trinity to three states or relations; or rather reduced the whole Trinity to the one person of the Father, making the *Word* and *Holy Spirit* to be only emanations or virtues.

SABINITES LAPIS, a name given to a stone, in which are preserved the leaves of the common savin.

SABLE, in Zoölogy, the name of a small animal of the weasel kind, the fur of which is highly valued. In Heraldry, *Sable* is the black colour in the arms of a family.

SABRE, a kind of sword, or scimeter, with a very broad and heavy blade, thick at the back, and a little falcatoid or crooked towards the point. In the use of this weapon the Turks are said to be so exceedingly dexterous, as to cleave a man quite down with a single stroke. Damascus was formerly famous for its manufacture of sabres.

SACCHARINE ACID. See *OXALIC Acid*.

SACCHAROMETER, in the Arts, an instrument for ascertaining the value of worts, and the strength of different kinds of malt liquors. The name signifies a measurer of sweetness.

SACCHARUM, *SUGAR*, or the *Sugar Cane*, a genus of the digynia order, in the triandria class of plants; and in the natural method ranking under the fourth order, gramina. The calix is two-valved; the corolla is also bivalved. There are eleven species. See *SUGAR*.

SACCOLATS, salts formed from the sacclactic acid, and but little known.

SACERDOTAL, something belonging to the priesthood.

SACK or *WOOL*, a quantity of wool containing just twenty-two stone, and every stone fourteen pounds. In Scotland, a sack is twenty-four stone, each stone containing sixteen pounds.

SACK of Cotton Wool, a quantity from one hundred and a half to four hundred weight.

SACKS of Earth, in Fortification, are canvass bags filled with earth. They are used in making entrenchments in haste, to place on parapets, or the head of breaches, &c. or to repair them when beaten down.

SACKBUT, a musical instrument of the wind kind, being a sort of trumpet, though different from the common trumpet both in form and size: it is fit to play a bass, and is contrived to be drawn out or shortened according to the tone required, whether grave or acute.

SACLACTIC ACID, an acid obtained from gum and arabic, and other mucilaginous substances.

SACRAMENT, in general, denotes a sign of something holy or sacred. In the Christian church, baptism and the Lord's supper claim this term; and it has been defined in the ritual of the Establishment to mean, an outward and visible sign of an inward and spiritual grace. Few subjects have been made the occasion of more fierce and unholy contentions than this symbol of peace, good will, and brotherly love.

SACRE, or *SAKER*, in Ornithology, a species of falcon, exceedingly strong, bold, and active. Ray says, that it will seize upon the largest birds, and even young goats, for food.

SACRIFICE, an offering made to God on an altar. The institution is so ancient as to be deemed nearly coeval with human nature. In some form or other, its adoption seems to be universal. Among Christians, the term is generally restricted to the death of Christ, and the offerings by which that event was typified.

SACRILEGE, is church robbery, or a taking of things out of a holy place, as where a person steals any vessels, ornaments, or goods of the church.

SADAR, the Arabian name of the medicinal lotus, described by Dioscorides and many other ancient writers.

SADDLE, is a seat upon a horse's back, contrived for the convenience of the rider. The ancient Romans are supposed not to have made use of saddles and stirrups, and it has been thought that they did not come into use till the time of Constantine the Great, but this is a great error.

SADDLE, a small cleat or block of wood nailed upon the lower yard arms, to retain the studding sail booms in a firm and steady position; for this purpose the cavity on the lower part of the saddle conforms to the cylindrical surface of the yard to which it is attached, and in like manner the hollow on the upper side answers to the figure of the boom, and serves as a channel whereby it may run out or in along the yards, as occasion requires.

SADDLE, is also a name given to several circular pieces of wood, as the saddle of a bowsprit, saddle of a boom, &c.

SADDLER, one who makes saddles, and furnish necessities for equestrian equipment. The Saddlers' Company, in London, was incorporated in 1272.

SADDUCEES, an ancient Jewish sect, who denied the resurrection, and the existence of angels and spirits. They were the freethinkers of Israel, highly liberal in principles, but dreadfully cruel in practice.

SAFETY LAMP. To obviate the destructive effects of carburetted hydrogen gas, Sir Humphrey Davy turned his attention to the construction of a lamp which would prevent explosion; and upon the knowledge of the fact, that flame cannot pass through apertures of small diameter, he constructed what the miners have since, in gratitude, called the Davy. See *LAMP*.

SAFFRON, a well-known plant, much cultivated in Cambridgeshire and Essex, and also imported from France, Spain, and Sicily, but that of our own country, when unadulterated, is always preferred. It should be chosen not above a year old, in close, tough, compact cakes, moderately moist, staining the hands when rubbing it, and of the same colour within as on the outside. The cultivation of saffron is attended with much trouble, and requires extraordinary care, and no small degree of patience.

SAFFRON, *Meadow*, a poisonous plant, having a bulbous root, somewhat resembling that of a tulip. Under certain modifications, it has been recommended as a remedy for the gout; but we hear of more mischief than advantage resulting from its cultivation.

SAFFRON Tree, an East Indian shrub, which grows about two feet high. The flowers, which resemble those of the jessamine, never open but in the night, and seldom continue more than three or four days. They have no smell, but exhibit the colour of saffron, and their cordial virtues are much the same.

SAFFRON, is also a name given to several chemical preparations, from their resemblance in colour to vegetable saffron.

SAGAPENUM, a medicinal gum resin, whose smell resembles that of a pine.

SAGARA, in Hindoo Mythology, is a personification of the ocean.

SAGATHEE, a slight kind of woollen stuff, serge, or ratteen, sometimes mixed with a little silk.

SAGDA, the name of a particular stone of a green colour, having the property of attracting wood.

SAGE. See **SALVIA**.

SAGENE, a Russian long measure, five hundred of which make a verst, equal to seven English feet.

SAGGING to **LEEWARD**, the movement by which a ship makes a considerable lee-way, or is driven far to leeward of the course whereon she apparently sails. It is generally expressed of heavy sailing vessels, as opposed to keeping well to windward, or, in the sea phrase, holding a good wind.

SAGITTA, the *Arrow*, one of the northern constellations. See **CONSTELLATION**.

SAGITTA, in Trigonometry, is the same as the versed sine of any arch, and is so called, because it resembles a dart or arrow standing on the chord of an arc.

SAGITTA, in Geometry, is used by some old authors, to denote the absciss of any curve.

SAGITTARIUS, the *Archer*, γ , is the last of the autumnal, and the third of the southern signs, agreeably to the fixed zodiac; and the sun accordingly enters it on the 22d of November. But reckoning by the visible and moveable zodiac, Sagittarius is actually in possession of the first winter sign, for the sun enters it about the 7th of December, as is obvious by reference to the Celestial Globe.

Boundaries and Contents.—Sagittarius is bounded on the north by Scutum Sobieski and Antinous; east by Capricornus and Microscopium; south by Corona Australis, Indus, and Telescopium; and west by Scorpio. It contains sixty-nine stars, viz. five of the third magnitude, nine of the fourth, &c. One of the largest stars in this sign, and δ , is situated by the middle of the bow, and rises on the south-east by S. $\frac{1}{4}$ E. point of the horizon, at London. Its declination is $29^{\circ} 54' 33''$ south; its right ascension $272^{\circ} 21' 57''$; and it rises and culminates as in the following table, for the first day of every month in the year: Meridian altitude $8^{\circ} 34' 27''$.

MONTH.	RISES. ho. mi.	CULM. ho. mi.	MONTH.	RISES. ho. mi.	CULM. ho. mi.

SAGO, a simple brought from the East Indies, of considerable use in diet, as a restorative. It is produced from the pith of a kind of palm which grows in the East Indies, called the cycas circinalis.

SAGOUIN, in Zoology, the name of a beautiful species of monkey.

SAGUM, the name of a military garment worn by the Greeks, Romans, and Gauls, in the manner of a cloak or cassock.

SAGWIRE, a liquor in the East Indies, drawn from a tree of the palm kind, of the same nature as toddy or palm wine. It is refreshing, wholesome, but inebriating.

SAIC, a sort of Grecian ketch, which has no top-gallant sail nor mizzen sail.

SAIC, an assemblage of several breadths of canvass, or other texture, sewed together, and extended on or between the masts, to receive the wind, and impel the vessel through the water. The edges of the cloths or pieces of which a sail is composed are generally sewed together with a double seam, and the whole is skirted round at the edges with a cord called the bolt-rope.

SAICK, a Turkish vessel rigged in a peculiar manner, and well adapted for the conveyance of merchandise.

SAIGA, in Zoology, a species of antelope, the characters of which are, that the horns are pale, and almost transparent, distant at their bases, and bent in form of a lyre. It inhabits Poland, Moldavia, the Carpathian mountains, Caucasus, and may be found on the borders of the Caspian and Euxine sea. Its resi-

dence is generally in the open desert, in which salt springs abound, and its food is saline, acrid, and aromatic vegetables.

SAILS, are all contained either between three or four sides; or, as they are otherwise termed, they are either triangular or quadrilateral. The former of these are sometimes spread by a yard, as lateen sails, or by a stay, as stay sails, or by a mast, as shoulder of mutton sails; in all which cases the foremost leech or edge is attached to the yard, mast, or stay, throughout its whole length. The latter, or those which are four-sided, are either extended by yards, as the principal sails of a ship, or by yards and booms, as the studding sails, drivers, ringtails, and all those sails which are set occasionally; or by gaffs and booms, as the main-sails of sloops and brigantines. The principal sails of a ship are the courses or lower sails; the top sails, which are next in order above the courses, and the top gallant sails, which are extended above the top sails. The courses are, the main-sail, fore-sail, and mizzen; the sprit-sail, main stay-sail, fore stay-sail, and mizzen stay-sail: but more particularly the three first. The main stay-sail is rarely used, except in small vessels. In all the quadrilateral sails, the upper edge is called the head, the sides or skirts are called leeches, and the bottom or lower edge is termed the foot; if the head is parallel to the foot, the two lower corners are denominated clues, and the upper corners earings. In all triangular sails, and in those four-sided sails wherein the head is not parallel to the foot, the foremost corner at the foot is called the tack, and the after lower corner the clue: the foremost head is called the fore leech, and the hindmost the after-leech. The heads of most four-sided sails, and fore-leeches of lateen sails, are attached to their respective yard or gaff by a number of small cords called robands, or by a lacing, and the upper extremities are made fast by earings. The stay-sails, are extended upon stays between the masts, whereon they are drawn up or down occasionally, as the curtain slides on its rod, and their lower parts are stretched out by a tack and sheet. The main-sail and fore-sail have a rope and a large single block made fast to each clue; the ropes called tacks lead forward to the chess trees and bunnings, and the block receives a thick rope from aft, which is termed the sheet. The clues of the top-sails are drawn out to the extremities of the lower-yards, by two large ropes called top-sail sheets, and the clues of the top-gallant sails are in like manner extended upon the top-sail yard-arms by ropes called top-gallant sheets. The royals are set above the top-gallant sails, and the studding sails beyond the leeches or skirts of the main-sail and fore-sail, and of the top-sails and top-gallant sails, their upper and lower edges being extended by small yards, and by poles run out beyond the extremities of the yards for this purpose. These sails are, however, only used in moderate weather. All sails derive their name from the mast, yard, or stay, upon which they are extended. Thus the principal sail extended upon the main-mast is called the main-sail; the next above, which stands upon the main-top-mast, is termed the main-top sail; that which is spread across the main-top gallant mast, is named the main-top-gallant sail; the sail above it is called the main-royal. In the same manner there are the fore-sail, fore-top sail, fore-top-gallant sails, and fore-royal; the mizzen, mizzen-top sail, mizzen top-gallant sail, and mizzen royal. Thus also there are the main-stay sail, main top-mast-stay sail, main top-gallant-stay sail, and a middle stay sail, which stands between the two last; all these stay-sails are between the main and fore mast; the stay sails between the main and mizzen masts are the mizzen stay sail, the mizzen top-mast stay sail, the mizzen top-gallant stay sail, and sometimes a mizzen royal-stay sail. The sails between the fore-mast and the bowsprit are the fore stay-sail, the fore top-mast-stay sail, the jib, and sometimes a flying jib; and even a middle jib: there are besides two and sometimes three square sails extended by yards under the bowsprit and jib-booms, one called the sprit-sail, the second the spirit-sail top-sail, and the third the sprit-sail top-gallant sail; the studding sails being extended upon the different yards of the main-mast and fore-mast, are also named, according to their stations, the lower top-mast, or top-gallant studding-sails. The ropes by which the lower yards of a ship are hoisted up to their proper height on the masts are called the jears; in all other cases the ropes employed for this purpose are called halliards; hence the sails are expanded by halliards,

tacks, sheets, and bow lines; and are drawn up together, or trussed up, by bunt-lines, clue-lines, leech-lines, reef-tackles, slab-lines, and spilling-lines, the higher studding-sails, and the stay-sails are drawn down so as to be taken in by down-hauls, and the courses, top-sails, and top-gallant sails, are wheeled about the mast so as to suit the various directions of the wind by braces.

After SAILS, are those that belong to the main mast and mizzen. They keep the ship to windward, on which account ships sailing on a quarter wind require a head-sail and an after sail, one to countermand the other.

Netting SAIL, is only a sail laid over the nettings.

SAIL, is also applied to a vessel seen at a distance under sail, as "We saw three sail in the north-east."

To *Set SAIL*, is to expand the sails in order to begin the action of sailing. To *loose Sails*, is to unfurl them, and to let them hang loose to dry. To *make Sail*, is to extend an additional quantity of sail, so as to increase the ship's velocity. To *shorten Sail*, is to reduce or take in part of the sails. To *strike Sail*, is to lower it suddenly, which is particularly used in saluting or doing homage to a superior force, or to one whom the law of nations acknowledges as superior in certain regions. Thus all foreign vessels strike to an English man-of-war in the British seas. See the article *SALUTE*.

SAILING, in Navigation, denotes the act of conducting a vessel from one port to another, by means of the action of the wind upon her sails, being otherwise expressed by the most significant term, Navigation.

SAILING, is distinguished into different cases, according to the principles upon which the computations are founded, as *Plane Sailing*, *Middle Latitude Sailing*, *Mercator Sailing*, *Globular Sailing*, &c.

Plane SAILING, is that which is performed on a supposition of the earth being an extended plane surface, and by means of plane charts, in which case the meridians are considered as parallel lines, the parallels of latitude at right angles to the meridians, and the lengths of the degrees on the meridians, equator, and parallels of latitude, as every where equal. Here the principal terms are the latitude, distance, and departure; difference of latitude and rhumb, longitude having no place in plane sailing. It is obvious, however, that calculations conducted on these principles must be too erroneous to be depended upon in any case, and therefore it would be but wasting the reader's time to enter farther into an explanation of this case, which is now nearly if not wholly disused by navigators.

Traverse SAILING, may be defined compound plane sailing, being the method of working, or calculating traverse or compound courses so as to reduce them into one. This is used when a ship, having to sail from one port to another, is by reason of contrary winds, or other obstacles, obliged to tack and sail upon different courses, which are then to be brought into one; and hence the difference of latitude, departure, and other circumstances, determined as in plane sailing.

Globular SAILING, is the method of estimating a ship's motion and run, upon principles drawn from the globular figure of the earth. In this its most extended sense, globular sailing comprehends *Parallel*, *Mercator*, *Middle Latitude*, and *Great Circle Sailing*; for a definition of each see the following articles.

Parallel SAILING, is the sailing on a parallel of latitude, or parallel to the equator, of which there are three cases.

1. Given the distance and difference of longitude; to find the latitude, which is performed by the following rule:—As the difference of long.: the distance:: the radius: the cosine of the latitude.

2. Given the latitude and difference of longitude; to find the distance. Rule. As radius: the cosine of the latitude:: the difference of longitude: the distance.

3. The latitude and distance being given to find the difference of longitude. Rule: As cosine of latitude: radius:: the distance: the difference of longitude.

Middle Latitude SAILING, is a method of resolving the cases of globular sailing, by means of the middle latitude between that departed from and that come to. This method is not accurate, being founded on the principles of plane and globular sailing conjointly; viz. on a supposition that the departure is reckoned as a meridional distance in that latitude, which is the middle

parallel between the latitude sailed from and the latitude come to: which would be correct, if the cosine of a middle latitude was an arithmetical mean between the cosine of two extreme latitudes; and the departure between two places on an oblique rhumb, equal to the meridional distance in the middle latitude; but neither of these cases obtain. Yet when the parallels are near the equator, or near to each other, in any latitude, the error is not considerable. This method seems to have been invented on account of the easy manner in which the several cases may be resolved by the traverse table; and when a table of meridional parts is not at hand, the computations may be made as follows; viz. Take half the sum of the two given latitudes for the middle latitude, then say,

1. As cosine of mid. lat.: the radius:: the departure: diff. of longitude.

2. As cosine of mid. lat.: tan. of course:: diff. of lat.: diff. of longitude.

Right SAILING, is when a voyage is performed on some one of the four cardinal points. If a ship sail under the meridian on the north or south points, she varies not in longitude. If she sail under the equinoctial on the east or west points, she changes only the longitude. If from any place she sails directly east or west, she only alters the longitude.

Oblique SAILING, though in many cases the bearing and distances of places are determined by the solution of right-angled triangles, yet at sea there are several in which oblique positions can be observed. The doctrine of plane triangles is also applicable to the method of sailing by windward. It may be observed, in general, that when the wind is directly or partly against the ship's direct course to the place whither she is bound, she reaches her port by a kind of zigzag or z-like course, which is made by sailing with the wind first on one side of the ship and then on the other. The windward or weather-side of a ship is that side on which the wind blows, the other being called the leeward or lee side. When a ship sails the same way the wind blows, and the wind is said to be right aft, or right astern, her course is then sixteen points from the wind. When a ship sails with the wind blowing directly across her, she is said to have the wind on the beam, and her course is eight points from the wind. When a ship endeavours to sail towards that point of the compass from whence the wind blows, she is said to sail on the wind, or to ply to windward. A vessel sailing as near as she can to the point from whence the wind blows, is said to be close hauled: most ships will lie within about six points of the wind, but sloops and some other vessels will lie much nearer. When a ship sails on a wind, the windward tacks are always hauled forwards and the leeward sheets aft. The starboard tacks are aboard when the starboard side is to windward, and the larboard to leeward; the larboard tacks are aboard when the larboard side is to windward, and the starboard to leeward. In order to know how near the wind a ship will lie, observe the course she goes on each tack, when she is close-hauled; then half the number of points between the two courses will shew how near the wind that ship will lie. The most common cases in turning to windward may be constructed by the following precepts. Having drawn the meridian and parallel of latitude (or east and west line) in a circle representing the horizon of the place, mark in the circumference of the place of the wind; draw the rhumb passing through the place bound to, and lay thereon the distance of that place from the centre. On each side of the wind, lay off in the circumference the points of degrees, shewing how near the wind the ship can lie, and draw these rhumbs; the first course will be on one of these rhumbs, according to the tack the ship leads with; draw a line from the place bound to, parallel to the other rhumb, and meeting the first, and this will shew the course and distance on the other tack.

Mercator's SAILING, is the art of resolving the several cases of globular sailing by plane trigonometry, with the assistance of a table of meridional parts, or of logarithmic tangents. Meridional parts, miles, or minutes, are the parts by which the meridians in a Mercator's Chart increase, as the parallels of latitude decrease. The cosine of the latitude of any place being equal to the radius or semi-diameter of that parallel; therefore, in the true sea-chart, or nautical planisphere, this radius being the radius of the equinoctial, or whole sine of ninety degrees,

the meridional parts at each degree of latitude must increase as the secants of the arch contained between that latitude and the equinoctial decrease. The manner of working with the meridional parts, and logarithmic tangents, will appear from the two following cases.

1. Let the latitudes of two places be given, and the meridional difference of latitude between them be required. By the meridional parts, when they are on the same side of the equator, say the difference; when on different sides, the sum of the meridional parts answering to each latitude will give the meridional difference of latitude required. By logarithmic tangents, when they are on the same side of the equator, say the difference of the logarithmic tangents; when on different sides, the sum of the logarithmic co-tangents, abating the index of the half co-latitudes, divided by 12,63, will give the meridional difference of longitude required.

2. Let the latitude of one place and the meridional difference of latitude between that and another place be given, and the latitude of the other place be required. The sum of the meridional parts of the given latitude, and the given meridional difference of latitude, when they have like names, found in the table of meridional parts, will give the latitude sought. Or, multiply the given meridional differences of latitude by 12,68, and in the former case subtract, but in the latter case add the product to the logarithmic tangent of the given half co-latitude, the degrees corresponding to the tangent of the remainder, or of the sum, being doubled, will give the co-latitude required.

Circular, or Great Circle SAILING, is the art of finding what places a ship must go through, and what courses to steer, so that her track shall be in the arc of a great circle, or nearly so, passing through the place sailed from, and that bound to. This method of sailing has been proposed, because the shortest distance between two places on the sphere is an arc of a great circle intercepted between them, and not the spiral or rhumb passing through them, unless that rhumb coincides with a great circle which can only be on a meridian or on the equator. As the solutions of the cases in Mercator's sailing are performed by plane triangles, in this method of sailing they are resolved by the means of spheric triangles. To bring sailing to certain rules, M. Renau computes the force of the water against the ship's rudder, stern, and side, and that of the wind against her sails. In order to this, he, 1. considers all fluid bodies, as the air, water, &c. as composed of little particles, which when they act upon or move against any surface, do all move parallel to one another, or strike against the surface after the same manner. 2. That the motion of any body, with regard to the surface on which it is to strike, must be either perpendicular, parallel, or oblique. The author then proceeds to illustrate his observations with several examples.—Another author on this subject observes, when a ship changes her state of rest into that of motion, as in advancing out of a harbour, or from her station at anchor, she acquires her motion very gradually, as a body which arrives not at a certain velocity till after an infinite repetition of the action of its weight. The first impression of the wind greatly affects the velocity, because the resistance of the water might destroy it, since the velocity being but small at first, the resistance of the water which depends upon it will be very feeble, but as the ship increases her motion the force of the wind on her sails will be diminished; whereas, on the contrary, the resistance of the water on the bow will accumulate in proportion to the velocity with which the vessel advances. Thus the repetition of the degrees of force which the action of the sails adds to the motion of the ship, is perpetually decreasing, while, on the contrary, the new degrees added to the effort of resistance on the bow, are always augmenting. The velocity is then accelerated in proportion as the quantity added is greater than that which is subtracted; but when the two powers become equal, when the impression of the wind upon the sails has lost so much of its force as only to act in proportion to the opposite impulse of resistance on the bow, the ship will then acquire no additional velocity, but continue to sail with a constant uniform motion. The great weight of the ship may indeed prevent her from acquiring her greatest velocity, but when she has attained it, she will advance by her own intrinsic motion, without gaining any new degree of velocity, or lessening what she has acquired. She moves then by her own proper force,

in *vacuo*, without being afterwards subject either to the effort of the wind on the sails, or to the resistance of the water on the bow. If at any time the impulsion of the water on the bow should destroy any part of the velocity, the effort of the wind on the sails will revive it, so that the motion will continue the same. It must, however, be observed, that this state will only subsist when these two powers act upon each other in direct opposition, otherwise they will mutually destroy one another. The whole theory of working ships depends on this counter-action, and the perfect equality which should subsist between the effort of the wind and the impulsion of the water.

Order of SAILING, the general disposition of a fleet of ships when proceeding on a voyage or an expedition. It is generally found most convenient for ships of war to be formed in three parallel lines or columns.

SAIL-LOFT, a large apartment in dock-yards, where the sails are cut out and made.

SAILMAKER, a subaltern officer on board ships of war, who, with his mates, has the care of repairing or altering the sails, according to the captain's directions.

SAILOR, a person trained in the exercise of fixing the machinery of a ship, and managing her either at sea, or in a road or harbour.

SAINTFOIN, in Agriculture, a species of plant, of the artificial grass kind, frequently raised as food for cattle, both green and dried: it is sometimes called holy-hay, or wholesome hay, from its peculiar nutritive qualities. It rises in the stem from one to two feet high, and has tufts of red flowers from three to five inches in length. It was originally brought into this kingdom from France, or the Low Countries.

SAKER, a name formerly used for a small species of cannon, of which there were three sorts.

SAL AMMONIAC, in Chemistry, a salt composed of marine acid and ammonia, or the volatile alkali. This substance, highly refined, is called spirits of hartshorn.

SAL AMMONIAC, in the Materia Medica, is an inodorous salt, of a bitterish, acid, and cool taste; persistent in the air, and not easily reduced to powder.

SALACASE, the name given to a bird in the Philippine islands, by whose flight the inhabitants pretend to foretell future events.

SALAD HERBS, in Gardening, esculent plants, from which salads are collected. These are of various kinds, and are now procured at all seasons of the year.

SALAGRAMA, a stone found in the river Nepal, and considered by many sects of Hindoos as sacred, and containing something mystical.

SALAMANDER, a name given to several species of lizards. Of this creature many strangely fabulous accounts have been published.

SALARY, a stipend allowed to any person, in consideration of his industry and services, in another man's business.

SALYASIR, a small species of duck, not larger than a pigeon, inhabiting the marshes of the Philippine islands. It is most beautifully coloured.

SALE OF GOODS. If a man agrees for the purchase of goods, he shall pay for them before he carries them away, unless some term of credit is expressly agreed upon by the parties. If a man, upon the sale of goods, warrants them to be good, the law annexes to this contract a tacit warranty, that if they be not so, he shall make compensation to the purchaser: such warranty, however, must be on the sale. But if the vendor knew the goods to be unsound, and has used any art to disguise them, or if in any respect they differ from what he represents them to be to the purchaser, he will be answerable for their goodness, though no general warranty will extend to those defects that are obvious to the senses. If two persons come to a warehouse, and one buys, and the other, to procure him credit, promises the seller, "If he do not pay you, I will;" this is a collateral undertaking, and void without writing, by the statutes of frauds; but if he say, "Let him have the goods, I will be your paymaster," this is an absolute undertaking as for himself, and he shall be intended to be the real buyer, and the other to act only as his servant. The question in these cases is always, which party was originally trusted? For if the party to whom the goods are delivered was ever considered responsible, the an-

gagement of the other is void, unless it is in writing; after earnest is given, the vender cannot sell the goods to another without a default in the vender, and therefore, if the vendee does not come and pay, and take the goods, the vender ought to give him notice for that purpose: then if he does not come and pay, and take away the goods in convenient time, the agreement is dissolved, and he is at liberty to sell them to any other person.

SALEP, or SALOP. See SAGO.

SALET, in War, a light covering for the head, anciently worn by the light horse. It was little more than a bare cap, but would resist a heavy blow.

SALIENT, in Fortification, projecting; as, a salient angle.

SALIC, or SALIQUE LAW, *lex calica*, an ancient and fundamental law of the kingdom of France, usually supposed to have been made by Pharamond, or at least by Clovis, in virtue of which males only are to inherit. The ancient Romans allowed no sovereign women.

SALIVA. The fluid secreted in the mouth, which flows plentifully during a repast, is known by the name of saliva.

SALIVATION, in Medicine, a promoting of the flux of saliva by means of medicines, chiefly by mercury.

SALIX, the Willow, a genus of the diandria class of plants, and in the natural method ranking under the 50th order *amentaceae*. There are 63 species.

SALLYPORT, a large port on each quarter of a fireship, out of which the officers and crew make their escape into the boats as soon as the train is fired.

SALMO, the Salmon, in Natural History, a genus of fishes of the order abdominales. Gmelin enumerates fifty five species, and Shaw sixty-two, of which we shall notice the following: The common salmon. This abounds principally in the northern seas, which it quits at particular periods, to ascend rivers to a very considerable height, and deposit its spawn in them. In order to gain the favourite spots in rivers for this purpose, which are sometimes at the distance of several hundred miles from the ocean, these fishes will overcome difficulties of surprising extent, stemming the most rushing currents, and leaping with astonishing activity over various elevations. It is related that the same individual fishes will return to the same spot for a succession of seasons: in this respect exhibiting preferences similar to those of birds in similar circumstances.—The common trout is found in almost all the European streams, at least such as are cool and clear.—The red char is about a foot long, very similar in form to the common salmon, but more slender. It abounds in the rivers of Siberia, and the lakes of Germany; and in this country, in the lakes of Cumberland and Westmoreland. It is considered as one of the highest delicacies, and has the most brilliant colours and finest flavour, when inhabiting the coldest waters.—The smelt is about seven inches long, highly elegant, of a tapering form, and semi-transparent appearance.—The Greenland salmon. These abound off the coast of Greenland, where they are taken in vast quantities and dried, not only for the use of man but of cattle, for which they constitute a valuable food in winter. It is about the size of a smelt.—The grayling is about a foot and a half long, and abounds in the mountainous rivers in Europe and Asia. It resembles the trout in form. In some of the rivers of England, it is found in great perfection.

SALON, or SALOON, in Architecture, a very lofty spacious hall, vaulted at top, and sometimes comprehending two stories or ranges of windows.

SALSOLA, saltwort, kali, &c. a genus of the class and order pentandria digynia, and in the natural method ranking under the 12th order, *holoraceae*. The species are thirty-one. This plant when burnt produces harilla.

SALT, Common. The preparation of that kind of salt which is used for culinary and economical purposes (muriate of soda) depends upon the well-known fact, that the salt contained in the sea water or brine springs, being a fixed body, will not rise with the vapour of the water. All therefore that is wanted is to expose any water containing salt to evaporation.

SALT Marsh, such pasture lands as lie near the sea, and are sometimes overflowed with the tides.

SALTPETRE. See NITRE.

SALTPITS, reservoirs on a coast, to contain sea-water for

the purposes of making salt. The saltiness of the sea, lakes, &c. is a thing that has long puzzled and perplexed philosophers to account for. The honourable Mr. Boyle believes it to be supplied not only from rocks and masses of salt, which at the beginning were, or in some countries may yet be found, either at the bottom of the sea, or at the sides, where the water can reach them, but also from the salt which the rivers, rains, and other waters, dissolve in their passage through divers parts of the earth, and at length carry with them into the sea. Buffon, and most modern philosophers, acquiesce in this opinion.

SALTS, in Chemistry, are all the crystallizable acids, or alkalies, or earths, or combination of acids with alkalies, earths, or metallic oxides.

SALUTATION, the act or ceremony of saluting, greeting, or paying respect or reverence to any one. In their modes of salutation, most nations have something peculiar.

SALUTE, a testimony of respect or of homage rendered by the ships of one nation to those of another, or by ships of the same nation to a superior or an equal. This ceremony is variously performed, according to the circumstances, rank, or situation of the parties: it consists in firing a certain number of cannon or volleys of small arms, in striking the colours or topsails, or in three general shouts of the whole ship's crew mounted upon the yards and rigging for that purpose.

SALUTE, the principal regulations with regard to salutes in the royal navy are as follow:—When a flag-officer salutes the admiral and commander-in-chief of the fleet, he is to give him fifteen guns; but when captains salute him, they are to give him seventeen guns; the admiral or commander-in-chief of the fleet, is to return two guns less to flag-officers, and four less to captains. Flag-officers saluting their superior or senior officer, are to give him thirteen guns. Flag-officers are to return an equal number of guns to flag-officers bearing their flags on the same mast, and two guns less to the rest, as also to captains. When a captain salutes an admiral of the white or blue, he is to give him fifteen guns; but to vice and rear admirals, thirteen guns. When a flag-officer is saluted by two or more of his majesty's ships, he is not to return the salute till all have finished, and then to do it with such a reasonable number of guns as he shall judge proper. In case of the meeting of two squadrons, the two chiefs only are to exchange salutes. And if single ships meet a squadron consisting of more than one flag, the principal flag only is to be saluted. No salutes shall be repeated by the same ships, unless there has been a separation of six months at least. None of his majesty's ships of war, commanded only by captains, shall give or receive salutes from one another in whatsoever part of the world they meet. A flag-officer, commanding in chief, shall be saluted upon his first hoisting his flag, by all the ships present, with such a number of guns as is allowed by the first, third, or fifth articles. When any of his majesty's ships shall meet with any ship or ships belonging to any foreign prince or state, within his majesty's seas, (which extend to Cape Finisterre,) it is expected that the said foreign ships do strike their topsail, and take in their flag, in acknowledgment of his majesty's sovereignty in those seas; and if any shall refuse, or offer to resist, it is enjoined to all flag-officers and commanders, to use their utmost endeavours to compel them thereto, and not suffer any dishonour to be done to his majesty. And if any of his majesty's subjects shall so much forget their duty, as to omit striking their topsail in passing by his majesty's ships, the name of the ship and master, and from whence, and whither bound, together with affidavits of the facts, are to be sent up to the secretary of the admiralty, in order to their being proceeded against in the admiralty court. And it is to be observed, that in his majesty's seas, his majesty's ships are in no ways to strike to any; and that in no other parts, no ship of his majesty is to strike her flag or topsail to any foreigner, unless such foreign ship shall have first struck, or at the same time strike her flag or topsail, to his majesty's ship. The flag-officers and commanders of his majesty's ships are to be careful to maintain his majesty's honour, upon all occasions, giving protection to his subjects, and endeavouring, what in them lies, to secure and encourage them in their lawful commerce; and they are not to injure, in any manner, the subjects of his majesty's friends and allies. If a foreign admiral meets with any of his majesty's ships and salutes them, he shall re-

ceive gun for gun. If he be a vice-admiral, the admiral shall answer with two guns less. If a rear-admiral, the admiral and vice-admiral shall return two less; but if the ship be commanded by a captain only, the flag-officers shall give two guns less, and captains an equal number. When any of his majesty's ships come to an anchor in a foreign port or road, within cannon-shot of its forts, the captain may salute the place with such a number of guns as have been customary, upon good assurance of having the like number returned, but not otherwise. But if the ship bears a flag, the flag-officer shall first carefully inform himself how flags of like rank belonging to other crowned heads have given or returned salutes, and to insist upon the same terms of respect. It is allowed to the commanders of his majesty's ships in foreign parts, to salute the persons of any admirals, commanders-in-chief, or captains of ships of war of foreign nations, of foreign noblemen, or strangers of quality; as also the factories of the king's subjects, coming on board to visit the ship; and the number of guns is left to the commander, as shall be suitable to the occasion and the quality of the persons visiting; but he is nevertheless to remain accountable for any excess in the abuse of this liberty. If the ship visited be in company with other ships of war, the captain is not to make use of the civilities allowed in the preceding articles, but with leave and consent of the commander-in-chief, or the senior captain. Merchant-ships, whether foreigners or belonging to his majesty's subjects, saluting the admiral of the fleet, shall be answered by six guns less; when they salute any other flag-ships, they shall be answered by four guns less; and if they salute men-of-war commanded by captains, they shall be answered by two guns less. If several merchant-ships salute in company, no return is to be made till all have finished, and then by such a number of guns as shall be thought proper; but though the merchant-ships should answer, there shall be no second return. None of his majesty's ships of war shall salute any of his majesty's forts or castles in Great Britain or Ireland, on any pretence whatsoever.

SALVAGE, a third part of the value of any thing recovered from the enemy, after having remained in his possession twenty-four hours, or of any thing dragged up from the bottom of the sea.

SALVAGE-Money, is a reward allowed by the civil and statute law, for the saving of ships or goods from the danger of the sea, pirates, or enemies. When any ship is in danger of being stranded or driven on shore, justices of the peace are to command the constables to assemble as many persons as are necessary to preserve it; and, on its being preserved by their means, the persons assisting therein shall, in thirty days after, be paid a reasonable reward for the salvage, otherwise the ship or goods shall remain in the custody of the officers of the customs as a security for the same.

SALVER, a flat dish, commonly of silver or other precious metal, used to set glasses on to serve wine and other liquors.

SALVIA, *SAGE*, a genus of the monogynia order, in the dyginia class of plants, and in the natural method ranking under the 42d order, verticillatæ. There are 79 species.

SALVING SHEEP, in rural economy, the dressing of them with tar and grease, against the scab and other diseases.

SAMARITANS, an ancient sect among the Jews, still subsisting in some parts of the Levant, under the same name.

SAMARRA, a garment worn by heretics condemned by the Inquisition to be burned. It is a kind of frock made of sack-cloth, of a saffron colour, and painted with flames pointing downwards. Sometimes the unhappy victim's picture is drawn on it, with devils dragging him to perdition.

SAMBUCUS, *ELDER*, a genus of the trigynia order, in the pentandria class of plants, and in the natural method ranking under the 43d order, dumosæ. The species are only five.

SAMIA TERRA, in the *Materia Medica*, an earth of the marl kind, found in the island of Samos, and much used both in medicine, and in the pottery of the ancients.

SAMIEL, the Arabian name of a hot wind peculiar to the desert of Arabia.

SAMP, a name given in some parts of America to a sort of bread, made of maize or Indian corn. It has been said, that those who feed on this sort of bread are never subject to the stone, and that they also escape many other disorders.

SAMPHIRE, a *Sea Weed*, found on land in the vicinity of the sea shore, and which is troublesome and difficult to extirpate.

SAMPHIRE, for pickling, is a herb generally found growing on cliffs near the sea. The vicinity of Dover is supposed to produce some of the best.

SAMPLE, of grain, seed, merchandise, &c. is a small portion of any such articles as are to be sold, taken to market, or other places, for inspection, and as a specimen of the quality of the whole. The sample should never be superior to the aggregate which it represents.

SAMSON'S POST, a sort of pillar erected in a ship's hold, between the lower deck and the keelson, under the edge of a hatchway, and furnished with several notches, which serve as steps to ascend or descend. This post, being firmly driven into its place, not only serves to support the beam and fortify the vessel in that place, but also to prevent the cargo, or materials contained in the hold, from shifting to the opposite side by the rolling of the ship in a turbulent and heavy sea.

SAMSON'S POST, is also the name of a strong piece of timber used on board ships of war, which being placed in a sloping position, with the upper end resting against a beam, serves, by means of a single block lashed near its middle, to form a return for a tackle-fall, and therefore affords space for a greater number of hands to clap on.

SANATADOS, a name given by the natives of Sicily to the spongy excrescence found on the stalk of the dog-rose. This, dried, and reduced to a powder, they use as an antidote against the effects of venomous bites. When a viper has inflicted a wound, the place having been scarified, is sprinkled over with this powder, and large doses are taken internally in strong wine. Softened into a poultice with oil, it is said to be efficacious in the bite of a mad dog; the powder, mixed with broth or weak fluids, being at the same time taken internally. In favour of this specific, the opinion is very old. Pliny says that the root of the wild rose, from the stalk of which this substance grows, was revealed in a dream, for the curing of this dreadful malady. The application is at least worth trying, the substance being very common, and to be procured without expense or difficulty.

SANCTUARY, among the Jews, was the holiest and most retired place in the temple, in which was preserved the ark of the covenant, and into which no one was permitted to enter, except the high priest, and he only once a year.

SANCTUARY, in our ancient customs, denotes an asylum or place, privileged by the prince, for the security of persons guilty of capital offences.

SAND, in Natural History, a genus of fossils, of great use in the glass manufacture: the white writing sand being employed for making the white glass, and a coarse greenish looking sand for the green glass. In agriculture it seems to be the office of sand to make unctuous earths fertile, and fit to support vegetables, &c. See *HUSBANDRY*.

SAND Bags, in the art of War, are bags filled with earth or sand, holding each about a cubic foot; their use is to raise parapets in haste, or to repair what is beaten down.

SAND Flood, a terrible mischief incident to the lands of Suffolk, and some other parts of England; which are frequently covered with vast quantities of sand, rolling in upon them like a deluge of water from sandy hills in their neighbourhood. The flowing of sand, though far from being so tremendous and hurtful as in Arabia, is of very bad consequences in this country, as many valuable pieces of sand has thus been entirely lost. The best mode of stopping these ravages is to plant the arundo arenaria, and other plants which take firm root in the sand.

SANDAL, a rich kind of slipper, made of gold, silk, or other precious stuff, and worn chiefly by the Greek and Roman ladies. It consisted of a sole, having an opening at one extremity to embrace the ankle, but leaving the upper part of the foot bare. Sandals are still worn in many countries, under many variations.

SANDAL Wood, a beautifully coloured wood, hard, and fragrant in smell. It grows chiefly in India, and is valued for its medicinal virtues, and for inlaying in cabinet work.

SANDARACH, in Natural History, a very beautiful native fossil.

SANDARACH Gum, a resinous juice, which exudes from the trunks and thick branches of several kinds of juniper, in warm climates, and particularly on the coast of Africa, from incisions made in the bark. It has a light agreeable smell, and is sometimes used medicinally, but more generally in making varnishes.

SANDERLING, a small sprightly bird, found chiefly on the sea coasts. They are numerous on the shores of Cornwall.

SANDIVER, a whitish salt, continually cast up from the metal, as it is called, whereof glass is made; and swimming on its surface, is skimmed off.

SANDSTONE, in Mineralogy, is essentially composed of grains or particles of sand, either united by a mixture with other mineral substances, or adhering without any visible cement. The grains of sandstones are generally quartz, sometimes intermixed with felspar or slate.

SANGUIFICATION, in Physiology, the conversion into blood of the materials which supply the losses experienced by that fluid in nutrition, growth, secretion, and the other vital processes to which it is subservient.

SANGUINARIA, in Botany, a name suggested by the blood-coloured juice of the plant. Others, however, have derived the name from its efficacy in stopping hemorrhages.

SANGUINE, warm, bold, brisk, daring, abounding in blood.

SANGUINE Stone, a kind of jasper, brought from New Spain, of a dark brown colour, marked with spots of a blood-red. It is sometimes called blood-stone from its supposed virtue to stanch blood, either when applied to the affected part, having been first dipped in water, or by the patient grasping it in his hand.

SANHEDRIM, among the ancient Jews, the supreme council court, or court of judicature, in which were despatched all great affairs both of religion and civil policy.

SANIDIUM, in Natural History, a genus of fossils in the class of the selenitar.

SANIES, in Medicine, a serous putrid matter, issuing from wounds; it differs from pus, which is thicker and white.

SANQUA, in Botany, a shrub nearly resembling tea, and found in Japan. Its leaves, when dried, yield a fragrant smell. The Japanese females use the decoction for washing their hair. Thunberg says, the leaves are sometimes mixed with tea, to increase its odour.

SANTEO, in Botany, a name given by the people of Guinea to an herb, which being boiled in water, communicates a virtue to the fluid, that cures diseases in the eyes when washed with it.

SAP. The sap of plants, in general, is very compound in its nature; and contains most saccharine, mucilaginous, and albuminous matter in the album; and most tannin and extract in the bark. The cambium, which is the mucilaginous fluid found in trees between the wood and the bark, and which is essential to the formation of new parts, seems to be derived from these two kinds of sap; and probably is a combination of the mucilaginous and albuminous matter of one with the astringent matter of the other, in a state fitted to become organized by the separation of its watery parts.

SAP, or **SAPP**, in the art of War, is the digging deep under the earth of the glacis, in order to open a covered passage into the moat.

SAP-Colours, a name given to various expressed juices of a viscid nature, which are inspissated by slow evaporation for the use of painters; as saggreen, gamboge, &c.

SAPANARIA, a name given to several plants, because the leaves being bruised yields a substance producing a lather like soap.

SAPPHIRE. Telesia of Hany and corundum of Bournon. A valuable mineral of a beautiful blue or red colour, sometimes white, green, and yellow. After the diamond it is the hardest substance in nature. The constituents of the blue sapphire, according to Klaproth, are 92.5 alumina, 6.5 lime, and oxide of iron.

SAPINDUS, or **INDIAN SOAP**, the acrid rind of the fruit serving instead of soap, but not without hazard of injuring the texture of the cloth.

SAPONACEA TERRA, is a kind of native alkali, of the nitre found on the surface of the earth, mixed with dirt, &c. in the vicinity of Smyrna; and hence sometimes called Smyrna earth. It boils up apparently out of the ground, and presents

itself as a fine whitish salt. With other ingredients it is made into soap, and applied to other purposes.

SARABANDE, a dance said to be originally derived from the Saracens. The tune of the sarabande is both expressive and majestic.

SARCASM, in Rhetoric, a keen bitter expression, which has the true point of satire, by which the orator scoffs and insults his enemy; such was that of the Jews to our Saviour, "He saved others, himself he cannot save."

SARCOCOLL, a vegetable substance intermediate between sugar and gum, partaking in some measure of the properties of each, but certainly approaching nearer to sugar than to gum.

SARCOPHAGUS, a sort of stone coffin or grave, in which the ancients interred those whom they did not burn. The stone of which these receptacles were originally made, resembled a reddish pumice-stone. It had a saltish taste, and was reported to decompose every portion of the body, excepting the teeth, in about forty days.

SARDACHATES, a species of agate, frequently found on the margins of rivers in the East Indies.

SARDIAN, a precious stone, of a blood colour, semitransparent, and sometimes called carnelian.

SARDOA, a poisonous plant, which grows plentifully in Sardinia, sometimes called water crowfoot.

SARDONYX, a precious stone consisting of a mixture of the chalcedony and carnelian, sometimes in strata, but at other times blended together.

SARISSA, a long spear used by the Macedonians.

SARON, in Greek Mythology, the particular god that presided over sailors.

SAROS, a period of 223 lunar months.

SARPLAR OF WOOL, a quantity of wool, called sometimes a pocket, or half sack. A sack contains eighty tods, a tod two stones, and a stone fourteen pounds.

SARRASIN, in Fortification, a kind of portcullis, otherwise called a herse, hung with ropes over the gates of a town or fortress, and let fall in case of a surprise.

SARSAPARILLA, in Pharmacy, the root of the rough smilax of Peru, consisting of a great number of long strings hanging from one head; these long roots, the only parts made use of, are about the thickness of a goose quill, or thicker, flexible, and composed of fibres running their whole length; they have a bitterish, but not ungrateful taste, and no smell; and as to their medicinal virtues, they are sudorific and attenuant, and should be given in decoction, or by way of diet-drink.

SASHES, in Military language, are badges of distinction worn by officers, either over the shoulders or round the waist. They are made of crimson silk.

SASSAFRAS, in Pharmacy, the wood of an American tree of the laurel kind, imported in large straight blocks; it is said to be warm, aperient, and corroborant; and is frequently employed, with good success, for purifying the blood, for which purpose an infusion, in the way of tea, is a very pleasant drink; its oil is very fragrant, and possesses most of the virtues of the wood.

SASSOLIN, in Mineralogy, concrete native boracic acid, so called from being found on the banks of a hot spring at Sasso, in Italy.

SATELLITIAN MACHINE, a machine by which the motions of the satellites, or secondary planets, are produced by wheel work, in the same way that the motions of the primaries are effected by a planetarium. Several such machines have been invented.

SATELLITE, a secondary planet moving round another planet, as the moon round the earth.

SATIN SPAR, fibrous limestone.

SATIN, a kind of silken stuff, very smooth and shining. The wool is coarse, and hidden underneath the warp, which is fine, and stands out, and on this depends its gloss and beauty, which give its value and price. The finest satins are said to be at Florence and Genoa. Chinese satins, richly embroidered, were once in high estimation, but our own manufactures are at present equal in most respects to the foreign. The colours and flowers are various, and the price is regulated accordingly.

SATIRE, any discourse in which a person is reprehended; but more particularly a poem in which the follies and vices of persons are wittily exposed in order to their reformation.

SATISFACTION, in Law, a recompense made for an injury done, or the payment of money due on bond, judgment, or bill.

SATRAPA, or **SATRAPES**, in Persian Antiquity denotes an admiral, but more commonly the governor of a province.

SATURATION. Some substances unite in all proportions. Such, for example, as acids in general, and some other salts with water; and many of the metals with each other. But there are likewise many substances which cannot be dissolved in a fluid, at a settled temperature, in any quantity beyond a certain proportion. Thus water will dissolve only about one-third of its weight of common salt, and, if more be added, it will remain solid. A fluid which holds in solution as much of any substance as it can dissolve, is said to be saturated with it. But saturation with one substance does not deprive the fluid of its power of acting on and dissolving some other bodies, and in many cases it increases this power. For example, water saturated with salt will dissolve sugar; and water saturated with carbonic acid will dissolve iron, though without this addition its action on this metal is scarcely perceptible. The word saturation is likewise used in another sense by chemists: the union of two principles produces a body, the properties of which differ from those of its component parts, but resemble those of the predominating principle. When the principles are in such proportion that neither predominates, they are said to be saturated with each other; but if otherwise, the more predominant principle is said to be sub-saturated or under-saturated, and the other super-saturated or over-saturated.

SATURN. See **ASTRONOMY**.

SATURNALIA, feasts celebrated among the Romans, in honour of Saturn, in which riot and debauchery prevailed among all ranks. M. Dacier observes, that the Saturnalia were not merely to honour Saturn, but to keep in remembrance the golden age, when all mankind were on a level.

SATYR, in Mythology, a fabulous kind of demigod, who, with the fawns and sylvans, presided over groves and forests, under the direction of Pan.

SAUCER of a CAPSTAN, is a socket of iron let into a wooden stock or standard, called the step, resting upon and bolted to the beams. Its use is to receive the spindle or foot on which the capstan rests and turns round.

SAUCISSE, in the Military art, is a long train of powder sewed up in a roll of pitched cloth or leather, serving to set fire to mines. To every mine there are generally two, that if one fail, the other may take effect. Their length is determined by circumstances.

SAUCISSON, in Fortification, a kind of faggot made of thick branches of trees, bound together, to cover the men while exposed to the enemy's fire, when on some hazardous employment. It is also used to repair breaches, stop passages, and make traverses over wet ditches.

SAVINE. See **JUNIPER**.

SAVIOUR, Order St. a religious order in the Romish church, founded by St. Bridget, about the year 1345; and so called from its being pretended that our Saviour himself dictated to the foundress its constitutions and rules.

SAVORY, in Botany, a plant, of which the leaves are warm aromatic, of a grateful smell, and pungent to the taste. There are two kinds, the winter and summer savory.

SAW, an instrument which serves to cut into pieces several solid matters; as wood, stone, ivory, &c.

SAW MILLS, constructed for the purpose of sawing either timber or stone, are moved by animals, by water, by wind or, by steam. They may be divided into two kinds: 1st, those by which the motion of the saw is reciprocating; and 2dly, those in which the saws have a rotatory motion. Reciprocating saw mills for cutting timber, and moved by water, do not exhibit much variety in their construction. Fig. 1, in the plate shows the sectional elevation of a saw mill taken from Gray's Experienced Millwright. A A the shaft or axle, upon which is fixed the wheel B B, of 17½ or 18 feet diameter, containing 40 buckets to receive the water which impels it round. C C a wheel fixed upon the same shaft containing 96 teeth, to drive the pinion No. 2, having 22 teeth, which is fastened upon an iron axle or spindle, having a coupling box on each end, that turns the cranks, as D D, round. One end of the pole E is put on the crank, and its other end moves on a joint or iron bolt at F in the lower end

of the frame G G. The crank D D being turned round in the pole E moves the frame G G up and down, and these having saws in them, by this motion cut the wood. The pinion No. 2, may work two, three, or more cranks, and thus move as many frames of saws. No. 3, an iron wheel having angular teeth, which one end of the iron K takes hold of, while its other end rolls on a bolt in the lever H H. One end of this lever moves on a bolt at I, the other end may lie in a notch in the frame G G, so as to be pushed up and down by it. Thus the catch K pulls the wheel round, while the catch L falls into the teeth, and prevents it from going backwards. (See **UNIVERSAL LEVER**.) Upon the axle of No. 3, is also fixed the pinion No. 4, taking into the teeth in the under edge of the iron bar that is fastened upon the frame T T, on which the wood to be cut is laid; by this means the frame T T is moved on its rollers S S, along the fixed frame U U; and of course the wood fastened upon it is brought forward to the saws as they are moved up and down by reason of the turning round of the crank D D. V V, the machine and handle to raise the sluice when the water is to be let upon the wheel B B to give it motion. By pulling the rope at the longer arm of the lever M, the pinion No. 2, is put into the hold or grip of the wheel C C, which drives it; and by pulling the rope R, this pinion is cleared from the wheel. No. 5, a pinion containing 24 teeth driven by the wheel C C, and having upon its axle a sheave, on which is the rope P P, passing to the sheave No. 6, to turn it round; and upon its axle is fixed the pinion No. 7, acting on the teeth in an iron bar upon the frame T T, to roll that frame backwards when empty. By pulling the rope at the longer arm of the lever N, the pinion, No. 5, is put into the hold of the wheel C C; and by pulling the rope O it is taken off the hold. No. 8, a wheel fixed upon the axle No. 9, having upon its periphery angular teeth, into which the catch No. 10, takes: and being moved by the lever attached to the upper part of the frame G, it pushes the wheel No. 8, round; and the catch No. 11, falls into the teeth of the wheel, to prevent it from going backwards, while the rope rolls in its axle, and drags the logs or pieces of wood in at the door Y, to be laid upon the moveable frames T T, and carried forward to the saws to be cut. The catches No. 10, 11, are easily thrown out of play when they are not wanted. The gudgeons in the shafts, rounds of the cranks, spindles and pivots, should all turn round in cuds or bushes of brass. Z a door in one end of the mill-house, at which the wood is conveyed out when cut. W W, walls of the mill-house. Q Q, couples or framing of the youth. X X X, &c. windows to admit light to the house.

2. Sawmills for cutting blocks of stone are generally, though not always, moved horizontally; the horizontal alternate motion may be communicated to one or more saws by means of a rotatory motion, either by the use of cranks, &c. or in some such way as the following. Let the horizontal wheel A, B, D, C. fig. 2, drive the pinion O p N, this latter carrying a vertical pin P, at the distance of about ¼ of the diameter from the centre. This pinion and pin are represented separately in fig. 3. Let the frame W S T V, fig. 2, carrying four saws, marked 1, 2, 3, 4, have wheels V, T, W, W, each running in a groove or rut, whose direction is parallel to the proposed direction of the saws; and let a transverse groove P R, whose length is double the distance of the pin P from the centre of the pinion, be cut in the saw frame to receive that pin. Then as the great wheel revolves, it drives the pinion, and carries round the pin P; and this pin, being compelled to slide in the straight groove P R, while by the rotation of the pinion on which it is fixed its distance from the great wheel is constantly varying, it causes the whole saw frame to approach to and recede from the great wheel alternately, while the grooves in which the wheels run confine the frame so as to move in the direction T t, V v. Other blocks of stone may be sawn at the same time by the motion of the great wheel, if other pinions and frames running off in the directions of the respective radii E B, E A, E C, be worked by the teeth at the quadrantal points B, A, and C. And the contrary efforts of these four frames and pinions will tend to soften down the jolts, and equalize the whole motion. The same contrivance of a pin fixed at a suitable distance from the centre of a wheel, and sliding in a groove, may serve to convert a reciprocating into a rotatory motion; but it will not be preferable to the common conversion by means of a crank.

Fig 1

3. When saws are used to cut blocks of stone into pieces having cylindrical surfaces, a small addition is made to the apparatus. See figs. 4 and 5. The saw, instead of being allowed to fall in a vertical groove as it cuts the block, is attached to a lever or beam FG, sufficiently strong: this lever has several holes pierced through it, and so has the vertical piece ED, which is likewise moveable towards either side of the frame in grooves in the top and bottom pieces AL, DM. Thus the length KG of the radius can be varied at pleasure, to suit the curvature of NO; and as the saw is moved to and fro by proper machinery in the direction CB, BC, it works lower and lower in the block, while being confined by the beam FG, it cuts the cylindrical portion from the block P as required.

When a completely cylindrical pillar is to be cut out of one block of stone, the first thing will be to ascertain in the block the position of the axis of the cylinder; then lay the block so that such axis shall be parallel to the horizon, and let a cylindrical hole of from one to two inches diameter be bored entirely through it. Let an iron bar whose diameter is rather less than that of this tube, be put through it, having just room to slide freely to and fro as occasion may require. Each end of this bar should terminate in a screw, on which a nut and frame may be fastened; the nut frame should carry three flat pieces of wood or iron, each having a slit running along its middle nearly from one end to the other, and a screw and handle must be adapted to each slit; by these means the frame work at each end of the bar may readily be so adjusted as to form equal isosceles or equilateral triangles; the iron bar will connect two corresponding angles of these triangles, the saw to be used two other corresponding angles, and another bar of iron and of wood the two remaining angles, to give sufficient strength to the whole frame. This construction, it is obvious, will enable the workmen to place the saw at any proposed distance from the hole drilled through the middle of the block; and then by giving the alternating motion to the saw frame, the cylinder may at length be cut from the block, as required. This method was first pointed out in the Collection of Machines approved by the Paris academy. If it were proposed to saw a conic frustum from such a block, then let two frames of wood or iron be fixed to those parallel ends of the block which are intended to coincide with the bases of the frustum, circular grooves being previously cut in these frames, to correspond with the circumferences of the two ends of the proposed frustum; the saw being worked in these grooves will manifestly cut the conic surface from the block. This, we believe, is the contrivance of Sir George Wright.

The best method of drilling the hole through the middle of the proposed cylinder seems to be this: on a carriage running upon four low wheels let two vertical pieces (each having a hole just large enough to admit the borer to play freely) be fixed two or three feet asunder, and so contrived that the pieces and holes to receive the borer may, by screws, &c. be raised or lowered at pleasure, while the borer is prevented from sliding to and fro by shoulders upon its bar, which are larger than the holes in the vertical pieces, and which, as the borer revolves, press against those pieces: let a part of the boring bar between the two vertical pieces be square, and a grooved wheel with a square hole of a suitable size be placed upon this part of the bar, then the rotatory motion may be given to the bar by an endless band which shall pass over this grooved wheel and a wheel of a much larger diameter in the same plane, the latter wheel being turned by a winch handle in the usual way. As the boring proceeds, the carriage with the borer may be brought nearer and nearer the block, by levers and weights, in the same manner as is described under the article *Boring of* ORDNANCE.

4. Circular saws, acting not by a reciprocating but by a rotatory motion, have been long known in Holland, where they are used for cutting wood wanted in veneering. They were introduced into this country, we believe, by General Benthham, and are now used in the dock-yard at Portsmouth, the Royal Arsenal, Woolwich, and in a few other places: but they are not, as yet, so generally adopted as might be wished, considering how well they are calculated to abridge labour, and to accomplish with expedition and accuracy what is very tedious and irksome to perform in the usual way. Circular saws may be made to turn either in horizontal, vertical, or inclined planes;

and the timber to be cut may be laid upon a plane inclined in any direction; so that it may be sawn by lines making any angle whatever, or at any proposed distance from each other. When the saw is fixed at a certain angle, and at a certain distance from the edge of the frame, all the pieces will be cut of the same size, without marking upon them by a chalked line, merely by causing them to be moved along and keeping one side in contact with the side of the frame; for then, as they are brought one by one to touch the saw revolving on its axle, and are pressed upon it, they are soon cut through.

Mr. Smart, of Ordnance Wharf, Westminster-bridge, has several circular saws, all worked by a horse in a moderate sized walk: one of these, intended for cutting and boring tenons used in this gentleman's hollow masts, is represented in fig. 6. NOPQR is a hollow frame, under which is part of the wheel-work of the horse-mill.—A, B, D, C, E, F, are pulleys, over which pass straps or endless bands, the parts of which out of sight run upon the rim of a large vertical wheel: by means of this simple apparatus, the saws S, S', are made to revolve upon their axles with an equal velocity, the same band passing round the pulleys D, C, upon those axles; and the rotatory motion is given to the borer G by the band passing over the pulley A. The board I is inclined to the horizon in an angle of about 30 degrees; the plane of the saw S' is parallel to that of the board I, and about $\frac{1}{4}$ of an inch distant from it, while the plane of the saw S is vertical, and its lowest point at the same distance from the board I. Each piece of wood K out of which the tenon is to be cut is four inches long, an inch and a quarter broad, and $\frac{1}{4}$ of an inch thick. One end of such piece is laid so as to slide along the ledge at the lower part of the board I; and as it is pushed on by means of the handle H, it is first cut by the saw S', and immediately after by the saw S: after this the other end is put lowest, and the piece is again cut by both saws; then the tenon is applied to the borer G, and as soon as a hole is pierced through it, it is dropped into the box beneath. By this process, at least 30 tenons may be completed in a minute, with greater accuracy than a man could make one in a quarter of an hour, with a common handsaw and gimblet. The like kind of contrivance may, by slight alterations, be fitted for many other purposes, particularly all such as may require the speedy sawing of a great number of pieces into exactly the same size and shape. A very great advantage attending this sort of machinery is, that, when once the position of the saws and frame is adjusted, a common labourer may perform the business just as well as the best workman.

Mr. Brunel, a well-known civil engineer, took out a patent for saw-machinery, in May, 1805. The following is an abridgement of his specification. The saws are circular, and turn upon an axis passing through their centre. When they are too large to be made with sufficient strength of only one piece of steel, they may be constituted of two, four, eight, &c. pieces, and the joining edge of one plate must be hollow, to receive the sharp edge of that which is to be fitted into it. To augment the strength of the plates, flanches may be closely fitted to them, several pieces of leather or of paper being interposed, by means of which, and screws duly applied, the whole may be made very firm and strong. The improvements in the machinery for sawing timber easily and expeditiously, consist in the modes of laying and holding the piece of wood in the carriage or drag, in the facility of shifting the saw from one cut to another, and in the practicability of sawing both ways either towards or from the saw or saws. Each circular saw is adjusted upon a cylindrical spindle, which turns within rodings; the motion being communicated by means of a strap or band turning about a proper drum-wheel, and moved by any of the usual actuating powers, as wind, water, steam, animals, &c. The piece of timber being placed upon a drag or carriage, is held fast by means of clamps; and the carriage is moved towards and from the saw by a handle or crank communicating, by the assistance of cog-wheels, to a pinion which engages in a horizontal rack running under the frame of the carriage. This carriage is furnished with rollers serving to ease its longitudinal motion, and is intended to be moved by hand, so that its velocity may be varied at pleasure: the length of this carriage must obviously be proportionate to the size of the timber generally cut by the saw. After the saw has performed one cut, instead of moving

the timber, the saw itself is moved sidewise, that is, in the direction of its axle, by means of screws, after a method which may be easily conceived, till it is brought to the proper position for the next cut, when an adjusting or fixing screw prevents any lateral motion, and the rotary motion of the saw, and the rectilinear motion of the wood, may be resumed. Circular wedges are used, being intended to revolve by the motion of the log to follow the cut opened by the saw, and by that means to ease the friction, and steady the piece of timber. Sometimes an instrument composed of several parallel plates of metal may be employed instead of the circular wedges. When several saws are adjusted on one spindle, a piece of timber may be converted into planks by being drawn once through under the saws. In that case the flanches of the saws are fixed upon an iron drum, and kept firmly in their relative parallel positions by four bolts. In order to lower the saws as they wear away, the side rails sustaining their axles may be depressed by means of wedges. The log of wood is not to lie close upon the carriage or drag, but upon some transverse pieces, which may be moved if requisite when they come near the saw. Some very complete and extensive saw-mills have been recently erected by Mr. Brunel, in the carriage department of the Royal Arsenal, Woolwich, under the superintendence of Major-General Cuppage and Colonel Miller. Among the numerous purposes for which saws are employed, is that of cutting off the tops of piles. When these are below water, some additional mechanism is necessary to cause the saws to work in a horizontal plane at a suitable depth. Different contrivances for this purpose, with illustrative engravings, are described by M. Hachette, *Traité des Machines*, p. 252—275.

Saw-Mills are of greater antiquity than is generally supposed. So early as the fourth century, a saw-mill was erected on the small river Roer, in Germany: it is probable, however, that this was but a rude contrivance, as we find writers of more modern times, speaking of saw-mills as new and uncommon. The old construction had therefore very likely been lost, or the improvement was so great, as to cause the more modern to be looked upon as new inventions. Saw-mills have been in use more than four hundred years, for upon the discovery of Madeira in 1420, mills were erected there for sawing the various excellent timber with which the island abounded. The city of Breslaw had a saw-mill in 1427, which produced a yearly rent of three marks. Erfurt had a saw-mill in 1490. In Norway the first saw-mill was built in 1530. Soon after, the first saw-mill was built in Holstein, another at Joachimstall. In 1555, the Bishop of Ely, ambassador from Queen Mary to the court of Rome, having seen a saw-mill at Lyons, it was thought worthy of a particular description. It was not, however, until the sixteenth century that saw-mills received the great improvement of having several different saw blades, by which a piece of timber was cut into many planks at the same time. At Saardam, in Holland, were erected a number of saw-mills, where a great many still remain, notwithstanding more than a hundred have been given up of late years. The largest saw-mill ever constructed is in Sweden, where a water-wheel, twelve feet in breadth, drives, at the same time, no less than seventy-two saws. In the seventeenth century, saw-mills were introduced into England, attended with the most violent opposition from the sawyers, who apprehended that they would be the means of depriving them of their subsistence. Some that were undertaken were abandoned at the onset, and others were destroyed by the populace. The saw-mills of the present day are of two distinct kinds; the circular, those that cut by a continuous rotary motion, and the reciprocating, which operate as the common pit or frame saw. The circular saw-mills are for the most part used for cutting up timber of small dimensions; and the reciprocating for large timber, in forming beams, rafters, planks, &c. out of large timber. The most important machinery of the kind was erected by Brunel, under the joint co-operation of Dr. Gregory, at Portsmouth.

Eastman's Improved Saw-Mill.—Some important improvements have recently been made by Robert Eastman, of Brunswick Maine, United States, in sawing machines; the distinguishing features of which consist in a rotary saw of a superior construction to the common circular saw, and in the improved manner in which the logs are sawn. Instead of a continued

series of teeth round the periphery of the plate like other circular saws, Eastman's has only eight, or rather only four cutting instruments (each containing two teeth) placed at equal distances on the circumference, and projecting from it; these instruments are called section teeth. The saving of labour is calculated at full three-fourths, and the surface of the timber is smoother than when cut by the full-teethed saw. On the saw plate are fixed instruments called sappers, which being placed nearer to the centre, do not enter the wood so deeply as the saw, and are adjusted so as merely to cut off the extraneous sap part, rendering the edges of the planks uniformly straight, and all the cuts of equal dimensions. To understand which, it is, perhaps, necessary here to explain to the reader that the logs are by this machinery cut up lengthwise, not through the log, but from the circumference or exterior to the centre, as the radii of a circle; it having been ascertained that planks cut in this manner possess more durability, strength, and elasticity, than by the common method.

Fig. 7, in the plate, represents a side view of the machine, with a log in it ready for working. Fig. 8, is an end view of the same, exhibiting the log partly cut into sections. Fig. 9, is the saw, with its section teeth L L L L, and its sappers M M. Fig. 10, shews the shape of the sapper, with a groove, or slit, to admit of its being set according to the intended width of the plank.

A, fig. 7, is a strong frame of timber, about twenty-four feet long by five broad, the ends of which are seen at A A, fig. 8 B, fig. 7, is the carriage, about twelve feet long and four broad, the ends of which are seen at B B, fig. 8; it travels upon iron truck-wheels, grooved on their circumferences, and run upon iron slides, as shewn at K K, fig. 8. C, figs. 7 and 8, gives two views of the log under operation. The log is fixed into the carriage by means of iron centres, upon which it also revolves after each succeeding cut. At D D, figs. 7 and 8, is seen part of the saw. At E E, figs. 7 and 8, are situated the feed pulley and shifting gear. F, regulating pulleys. G, is an index for regulating the dimensions of the cuts. H, revolving levers and pins. I, the pin and fulcrum of the levers. J J, the stirrup screws and pins. Nearly in the middle of the frame is fixed the main shaft, (of cast iron,) which runs upon friction rollers, supported by stands on the floor. On this shaft is the saw with its sappers and section teeth. The motion is given by a band passing round the main pulley, and round a drum that runs under it; which may be driven by horse, steam, or water power. The method by which the saw is fed with the wood to be cut, and the return of the carriage for the succeeding cut, is too similar to our own to need a particular description. Its various arrangements are ingeniously contrived, and it may be justly termed a self-acting machine, for when once set in motion, no other aid, than the power which drives it, is requisite to its cutting a whole series of boards of uniform dimensions all round the log, having their thin-edged sides attached to the centre piece. These boards being removed, a second series of boards may be cut in like manner to the former, provided the log is big enough.

This machine furnishes a new method of manufacturing lumber for various useful purposes. Though the circular saw had previously been in operation in this country, and in Europe, for cutting small stuff, it had not, with the knowledge of the writer been successfully applied to solids of great depth; to effect which, the use of section teeth are almost indispensable. In his first attempts to employ the circular saw for the purpose of manufacturing clap boards, Eastman used one nearly full of teeth, for cutting five or six inches in depth into fine logs. The operation required a degree of power almost impossible to be obtained with the use of a band; the heat caused the plate to expand, and the saw to warp, or as it is termed, 'to get out of true.' To obviate these difficulties, he had recourse to the use of section teeth, and the improvement completely succeeded. The power required to perform a given quantity of work by the other method, was by this diminished at least three-quarters. The work, formerly performed by seventy or eighty teeth, was, by the last method, performed by eight teeth; the sawdust, which before had been reduced to the fineness of meal, was coarser, but the surface of the lumber much smoother than when with the full-teethed saw. The teeth are made in the

form of a hawk's bill, and cut the log up, or from the circumference to the centre. The saw may be carried by an eight-inch band, and when driven a proper speed (which is from ten to twelve hundred times per minute) will cut nine or ten inches in depth into the hardest white oak timber with the greatest ease. The sappers at the same time cut off from one to two inches of the sap, and straighten the thick edges of the lumber. The facility with which this saw will cut into such hard materials, may be supposed to result from the well-established principle, that where two substances in motion come in contact, their respective action on each other is in direct proportion to their respective velocities; thus a circular plate of iron put into a quick rotary motion, will with great ease penetrate hardened steel, or cut through a file when applied to its circumference; and the same principle is applicable to a saw for cutting wood. The requisite degree of velocity is obtained by the continuous motion of the circular saw; by which also it has greatly the advantage of one that has but a slow motion on account of dulling, as the teeth are but little affected, and being only eight in number, but a few moments' labour is required to sharpen them. If the velocity of the saw were slackened to a speed of but forty or fifty times per minute, it would require at least four such bands to carry it through a log as above described. One machine will cut from eighteen to twenty hundred of square feet of pine timber per day, and two of them may be driven by a common tub wheel, seven or eight feet in diameter, having six or seven feet head of water, with a cog-wheel and trundle-head, so highly geared as to give a quick motion to the drums, which should be about four feet in diameter. The machine is so constructed as to manufacture lumber from four to ten feet in length, and from two to ten inches in width, and of any thickness. It has been introduced into most of the New England states, and has given perfect satisfaction. The superiority of the lumber has for three years past been sufficiently proved in Brunswick Maine, where there have been annually erected from fifteen to twenty wooden buildings, and for covering the walls of which this kind has been almost universally used. The principal cause of its superiority to mill-sawed lumber, is in the manner in which it is manufactured, viz. in being cut towards the centre of the log, like the radii of a circle; this leaves the lumber feather-edged in the exact shape in which it should be, to set close on a building, and is the only way of the grain, in which weather-boards of any kind can be manufactured to withstand the influence of the weather, without shrinking, swelling, or warping off the building. Staves and heading, also, must be rived the same way of the grain, in order to pass inspection. The mill-sawed lumber, now universally used in the middle and southern states, and in the West Indies, for covering the walls of wooden buildings, is partly cut in a wrong direction of the grain, which is the cause of its cracking and warping off, and of the early decay of the buildings by the admission of moisture. That such is the operation, may be inferred by examining a stick of timber which has been exposed to the weather; the cracks caused by its shrinking all tend towards the heart or centre, which proves that the shrinking is directly the other way of the grain. It follows that lumber cut through or across the cracks, would not stand the weather in a sound state, in any degree to be compared with that which is cut in the same direction with them. One half the quantity of lumber manufactured in this way, will cover and keep tight and sound the same number of buildings for a hundred years, that is now used and consumed in fifty years. Add to this the reduction of expense in transportation, and of labour in putting it on, and we think every one must be convinced that the lumber manufactured in this improved way is entitled to the preference. In manufacturing staves and heading, a great saving is made in the timber, particularly as to heading, of which at least double the quantity may be obtained by this mode of sawing, to what can be procured in the old method of riving it; nor is the straight-grained, or good rift, indispensable for the saw, as it is for the purpose of being rived. The heading, when sawed, is in the form it should be, before it is rounded and doweled together, all the dressing required being merely to smooth off the outsides with a plane. Timber for staves ought to be straight in order to truss, but may be manufactured so exact in size, as to require but little labour to fit them for setting up.

Both articles are much lighter for transportation, being nearly divested of superfluous timber, and may be cut to any thickness required for either pipes, hogsheds, or flour barrels.

SAY, or SAYE, in Commerce, a kind of serge or woollen stuff, much used abroad for linings, and by the religious for shirts. It is often dyed green, and used for workmen's aprons.

SCAFFOLD, a timber work raised in the manner of an amphitheatre, to afford a good view of the object or company.

SCAFFOLD, is also the name of a stage raised for the execution of criminals. It is likewise an elevated temporary assemblage of poles and boards, to enable builders to attend to their work, in the erection of walls, roofs, &c.

SCAGLIOLA, an imitation of marble of any sort. It is hard, and when finished bears a fine polish. It is laid on brickwork like stucco, and worked off with iron tools. The Pantheon, in Oxford-street, London, had all its columns formed of this material; and when first done, they could scarcely be distinguished from real marble. If preserved from accident, this composition will retain its lustre for many years, without any considerable change of colour, or diminution of beauty.

SCALDED CREAM, in rural economy, such cream as is raised by a gentle heat. It is usually called clotted or clouted cream, and is chiefly made in Devonshire and Cornwall, in which counties it is much esteemed. The process is simple. The milk is put into a wide shallow pan, and after standing in it a few hours, the pan is placed over a clear but gentle fire. The cream then collects on the surface, and as the milk gets near boiling, it is taken off and left to cool. The cream is then skimmed off, and preserved for butter or other uses.

SCALE, a mathematical instrument, consisting of several lines, drawn on wood, brass, silver, &c. and variously divided according to the purposes it is intended to serve; whence it acquires various denominations, as the plain scale, diagonal scale, plotting scale, Gunter's scale, &c.

SCALE, in Music, the denomination first given to the arrangement made by Guido, of the six syllables, ut, re, mi, fa, sol, la; also called Gamut.

SCALES, in Natural History, the covering of fishes, serpents, lizards, &c. They are of various kinds, and seem to possess properties analogous to the horns and hoofs of animals. This is indicated by their properties being analyzed, their being cut, and their smell when burned.

SCALES, in Commerce, boards or metallic plates, suspended at the extremities of a beam, for weighing various articles, in order to ascertain their specific gravity and value.

SCALENE, a triangle, whose sides and angles are all unequal.

SCALING, the act of cleaning the inside of a ship's cannon by the explosion of a small quantity of powder.

SCALLION, a species of onion that never forms any bulb at the root. It is generally used green in the spring, before the real onions are ripe.

SCALPING, a barbarous custom among Indian warriors, of taking off the enemies' scalps with the hair on. These are preserved as trophies of prowess and victory; and those who produce the greatest number, receives from the chief the highest honours, and most ample rewards.

SCALY DISEASES, are such as affect the skin, the cuticle dividing into small detached white laminae. The elephantiasis, or leprosy, is of this description.

SCAMMONY, in the Materia Medica, a concreted vegetable juice of a plant of the same name.

SCANDALUM MAGNATUM, is the special name of a statute, and also of a wrong done to any high personage of the land, as prelates, dukes, marquesses, earls, barons, and other nobles; and also the chancellor, treasurer, clerk of the privy seal, steward of the house, justice of one bench or other, and other great officers of the realm, by false news, or horrible or false messages, whereby debates and discord between them and the commons, or any scandal to their persons, might arise. 2 Richard II. c. 5. This statute has given name to a writ granted to recover damages thereupon. It is now clearly agreed, that though there be no express words in the statute which give an action, yet the party injured may maintain one on this principle of law, that when a statute prohibits the doing of a thing, which if done might be prejudicial to another, in this case he may have an action on that very statute for his damages.

SCANDENS, in Botany, is a climbing stem, whether supported by tendrils like the vine, and the others like ivy, or its own procreant stems like the climbing nasturtium and the ivy-leaved fig.

SCANTLING, in Poetry, the measure of a verse by feet, in order to see whether or not the quantities regularly served. The term is chiefly used in regard to the Greek and Latin verses. Thus an hexameter verse is scanned by resolving it into six feet, a pentameter, by resolving it into five feet, &c.

SCANT, is a term applied to the wind when it becomes unfavorable to a ship's course, after having been fair. It is distinguished from a foul wind, as in the former a ship is still enabled to sail on her course, although her progress is considerably retarded, but in the latter she is obliged to deviate from it.

SCANTLING, the dimensions of any piece of timber with regard to its breadth and thickness.

SCANTLING, a measure, size, or standard, by which the dimensions of things are determined. The term is now chiefly applied to timbers, &c. in buildings.

SCAPE GOAT, in Jewish antiquities, the goat which was set at liberty on the day of solemn expiation, typically to bear away the sins of the people.

SCAPEMENT, among Watchmakers, denotes the general contrivance by which the pressure of the wheels which move always in one direction, and the reciprocating motion of the pendulum or balance, are accommodated to one another; when a tooth of a wheel has given the balance or pendulum a motion in one direction, it must quit it, that it may get an impulsion in the opposite direction; and it is this escaping of the tooth of the wheel from the balance or pendulum, or of the latter from the former, whichever we choose to call it, that has given rise to the general term. From the nature of a pendulum, it follows, that it need only to be removed from the vertical, and then let go, in order to vibrate and measure time. Hence it might seem that nothing is wanted but a machinery so connected with the pendulum as to keep a register, as it were, of the vibration. It could not be difficult to contrive a method of doing this, but more is wanted; the air must be displaced by the pendulum. This requires some force, and must therefore employ some part of the momentum of the pendulum. The pivot on which it swings occasions friction; the thread, or thin piece of metal by which it is hung, in order to avoid this friction, occasions some expenditure of force by its want of perfect flexibility or elasticity. These, and other causes, make the vibrations become more and more narrow by degrees, till at last the pendulum is brought to rest. We must, of course, have a contrivance in the wheelwork which will restore to the pendulum the small portion of force which it loses in every vibration. The action of the wheels, therefore, may be called a maintaining power, because it keeps up the vibrations. But this may affect the regularity of vibration. If it be supposed that the action of gravity renders all the vibrations isochronous, we must grant that the additional impulsion by the wheels will destroy that isochronism, unless it be so applied that the sum total of this impulsion and the force of gravity may vary so with the situation of the pendulum as still to give a series of forces, or a law of variation, perfectly similar to that of gravity. This cannot be effected, unless we know both the law which regulates the action of gravity, producing isochronism of vibration, and the intensity of the force to be derived from the wheels in every situation of the pendulum. Thus it appears that considerable scientific skill, as well as mechanical ingenuity, may be displayed in the construction of scapements; and the judicious consideration of them becomes of great importance to the artist; yet, notwithstanding this, no material improvement was made in them from the first application of the pendulum to clocks till the days of Mr. George Graham; nothing more was attempted before his time than to apply the impulse of the swing-wheel in such manner as was attended with the least friction, and would give the greatest motion to the pendulum. Dr. Halley discovered, by some experiments made at the Royal Observatory at Greenwich, that by adding more weight to the pendulum it was made to vibrate larger arcs, and the clock went faster; by diminishing the weight of the pendulum, the vibrations became shorter, and the clock went slower; the result of these experiments being diametrically opposite to

what ought to be expected from the theory of the pendulum, probably first raised the suspicion of Mr. Graham, who was not only skilled in practice, but in mathematical science, and was well qualified to examine the subject scientifically. He soon made such further trials as convinced him that this seeming paradox was occasioned by the retrograde motion, which was given to the swing-wheel by every construction of scapement that was at that time in use; and his great sagacity soon produced a remedy for this defect, by constructing a scapement which prevented all recoil of the wheels, and restored to the clock pendulum, wholly in theory, and nearly in practice, all its natural properties in its detached simple state. This scapement, with a few others of the most approved construction, will now be briefly described.

1. The scapement which has been in use for clocks and watches ever since their first appearance in Europe is extremely simple; and its mode of operation is too obvious to need much explanation. In fig. 1, see Plate, XY represents a horizontal axis, to which the pendulum P is attached by a slender rod, or otherwise. This axis has two leaves C and D attached, one near each end, and not in the same plane, but so that when the pendulum hangs perpendicularly, and at rest, the piece C inclines a few degrees to the right hand, and D as much to the left. They commonly make an angle of from 70 to 90 degrees; they are called by the name of pallets. AFB represents a wheel turning round on a perpendicular axis EO, in the order of the letters AFE B. The teeth of this wheel are cut into the form of the teeth of a saw, leaning forward, in the direction of the motion of the rim. As they somewhat resemble the points of an old-fashioned royal diadem, this wheel has got the name of the crown-wheel. In watches it is often called the balance-wheel. The number of the teeth is generally odd, so that when one of them B is pressing on a pallet D, the opposite pallet C is in the space between two teeth A and I. The figure represents the pendulum at the extremity of its excursion to the right hand, the tooth A having just escaped from the pallet C, and the tooth B having just dropped on the pallet D. It is plain, that as the pendulum now moves over to the left, in the arch PG, the tooth B continues to press on the pallet D, and thus accelerates the pendulum, both during its descent along the arch PH, and its ascent along the arch HG. It is no less evident, that when the pallet D, by turning round the axis XY, raises its point above the plane of the wheel, the tooth B escapes from it, and I drops on the pallet C, which is now nearly perpendicular. I presses C to the right, and accelerates the motion of the pendulum along the arch GP. Nothing can be more obvious than this action of the wheel in maintaining the vibrations of the pendulum. We can easily perceive also, that when the pendulum is hanging perpendicularly in the line XH, the tooth B, by pressing on the pallet D, will force the pendulum a little way to the left of the perpendicular, and will force it so much the further as the pendulum is lighter; and, if it be sufficiently light, it will be forced so far from the perpendicular, that the tooth B will escape, and then I will catch on C, and force the pendulum back to P, where the whole operation will be repeated. The same effect will be produced in a more remarkable degree, if the rod of the pendulum be continued through the axis XY, and a ball Q put on the other end to balance P. And, indeed, this is the contrivance which was first applied to clocks all over Europe, before the application of the pendulum. They were balance clocks. The force of the wheel was of a certain magnitude, and therefore able, during its action on a pallet, to communicate a certain quantity of motion and velocity to the balls of the balance. When the tooth B escapes from the pallet D, the balls are then moving with a certain velocity and momentum. In this condition, the balance is checked by the tooth I catching on the pallet C. But it is not instantly stopped. It continues its motion a little to the left, and the pallet C forces the tooth I a little backward. But it cannot force it so far as to escape over the top of the tooth I; because all the momentum of the balance was generated by the force of the tooth B; and the tooth I is equally powerful. Besides, when I catches on C, and C continues its motion to the left, its lower point applies to the face of the tooth I, which now acts on the balance by a long and powerful lever, and soon stops its further motion in that direction; and now, continuing to press on C, it

Scapements.

Page 216.

urges the balance in the opposite direction. Thus we see that in a scapement of this kind the motion of the wheel must be very hobbling and unequal, making a great step forward, and a short step backward, at every beat. This has occasioned the contrivance to get the name of the recoiling scapement, or the scapement of recoil. In this scapement the vibrations are quicker than if the balance or pendulum vibrated freely: for the recoil shortens the ascending part of the vibration, by contracting the extent of the arc, and the re-action of the wheel accelerates the descending part of the vibration. In this scapement, too, if the maintaining power be increased, the vibration will be performed in larger arcs, but in less time: because the greater pressure of the crown-wheel on the pallet will cause the balance to vibrate through larger arches; and the time will be less increased on this account than it will be diminished by the acceleration that pressure gives to the balance and the diminution of the time of recoil.

2. The preceding scapement not being well adapted to such vibrations as are performed through arcs of a few degrees only, another construction has been made, which has been in constant use for about a century in clocks, with a long pendulum beating seconds. In fig. 2, AB represents a vertical wheel called the swing-wheel, having thirty teeth. CD represents a pair of pallets connected together, and moveable in conjunction with the pendulum on the centre or axis F. One tooth of the wheel, as shewn in the figure, rests on the inclined surface of the inner part of the pallet C; on which its disposition to slide tends to throw the point of the pallet further from the centre of the wheel, and consequently assists the vibration in that direction. While the pallet C moves outwards and the wheel advances, the point of the pallet D of course approaches towards the centre in the opening between the two nearest teeth; and when the acting tooth of the wheel slips off, or escapes from the pallet C, another tooth on the opposite side immediately falls on the exterior inclined face of D, and by a similar operation tends to push that pallet from the centre. The returning vibration is thus assisted by the wheel, while the pallet C moves towards the centre, and receives the succeeding tooth of the wheel, after the escape from the point of D. Thus may the alternation be conceived to go on without limit. In this scapement, as well as the former, the vibrating part is constantly under the influence of the maintaining power, except during the interval of the drop, or actual escape of the wheel from one pallet to the other. One principal recommendation of this scapement seems to have been the facility with which it affords an index for seconds in the face of the clock. Though the pendulum, according to this construction, is constantly connected with the maintaining power in a clock, yet the variations of that power have not the same mischievous effect as in a watch, because the momentum of the pendulum, compared with the impulse of the maintaining power, is prodigiously greater in the former of these instruments. A very considerable change in the maintaining power of a clock with a long pendulum will only cause a variation of a few seconds in the daily rate.

3. Mr. Graham's scapement, already spoken of, was a considerable improvement upon that just described. He took off part of the slope furthest from the points of the pallets; and instead of that part he formed a circular or cylindrical face, having its axis in the centre of motion. Pallets of this kind are shewn at the lower part of fig. 2, at E and G, having H for their centre or axis. A tooth of the wheel is seen resting upon the circular inner surface of the pallet G, which therefore is not affected by the wheel, excepting so far as its motion, arising from any other cause, may be affected by the friction of the tooth; and this resistance is exceedingly minute, not amounting to one-eighth of the pressure on the arch. Nay, we think it appears from the experiments of Coulomb, that, in the case of such minute pressure on a surface covered with oil, there is no sensible retardation analogous to that produced by friction, and that what retardation we observe arises entirely from the clamminess of the oil. If the vibration of the pendulum be supposed to carry G outwards, the slope surface will be brought to the point of the tooth, which will slide along it, and urge the pallet outwards during this sliding action. When the tooth has fallen from the point of this pallet, an opposite tooth will be received on the circular surface of E, and will not affect the

variation, excepting when the slope surface of E is carried out so as to suffer the tooth to slide along it. This contrivance is known by the name of the dead beat, or the dead scapement; because the seconds index stands still after each drop, whereas the index of a clock with a recoiling scapement is always in motion, hobbling backward and forward.

In this scapement, an increase of the maintaining power renders the vibrations larger and slower: because the greater pressure of the tooth on the edge of the pallet throws it round through a greater arch: and its increased pressure on both surfaces of the pallet retards its motion.

4. The effect of the escapement which has been called horizontal, because the last wheel in watches of this construction has its plane parallel to the rest of the system, is similar to that of the dead beat scapement of Graham. In fig. 5, the horizontal wheel is seen with twelve teeth, upon each of which is fixed a small wedge supported above the plane of the wheel, as may be seen at the letters A and B. On the verge of the balance there is fixed part of a hollow cylinder of steel or other hard material, the imaginary axis of which passes through the pivots of the verge. C represents this cylindrical piece, into which the verge D may be supposed to have fallen. While the vibration causes the cylindrical piece to revolve in the direction which carries its anterior edge towards the axis of the wheel, the point of the wedge will merely rub the internal surface, and no otherwise affect the vibration of the balance than by retarding its motion. But when the return of the vibration clears the cylinder of the point of the wedge D, the wheel will advance, and the slope surface of the wedge acting against the edge of the cylinder will assist the vibration of the balance. When the edge of the cylinder arrives at the outer point of the wedge D, its posterior edge must arrive at the position denoted by the dotted lines of continuation; immediately after which the wedge or tooth E will arrive at the position e, and rest on the outer surface of the cylinder, where it will produce no other effect than that of retardation from friction, as was remarked with regard to the wedge D, until the course of the vibration shall bring the posterior edge of the cylinder clear of the point of the wedge. In this last situation, the wedge will act on the edge of the cylinder, and assist the vibration, as in the former case, until that edge shall arrive at the outer or posterior point of the wedge, immediately after which the leading point will fall on the inner surface of the cylinder in the first position, as was shewn in the wedge D.

Horizontal watches were greatly esteemed during the last thirty years, until lately, when they gave place to those constructions which are known by the name of detached or free scapements. In the common scapement, fig. 1, an increase of the maintaining power increases the recoil, and accelerates the vibration; but with the horizontal scapement there is no recoil; and an increase of the maintaining power, though it may enlarge the arc of vibration, will not necessarily diminish or alter the time. It is accordingly found, that the experiment of altering the maintaining power by the application of the key does not alter the rate in the same perceptible manner as in common watches.

5. Fig. 6, represents the free scapement of our best portable time-pieces. Fig. 4, exhibits the scapement on a large scale. On the verge of the balance is fixed a circular piece of sapphire, or of hard steel, E L, out of which a sectoral piece is cut. H G is a straight spring fixed near its extremity H, and having at the other extremity a pin G, against which one of the teeth of the wheel D rests when the train is at rest. This spring has a slight tendency towards the centre of the wheel, but is prevented by the stop K from throwing the pin further inwards than just to receive the point of the tooth. I is a very slender spring fixed at the end I, and pressing very slightly against the pin G, in a direction tending to throw it from the wheel D, but which on account of the greater power of H G it cannot effect. It may be observed that the spring I proceeds a little beyond the pin G.—F is a lever proceeding from the verge of the balance directly opposite the end of the spring I, and long enough to strike it in its vibration. The action is as follows:—From the pressure of the main spring, the wheel (fig. 4.) is urged from D towards F, but is prevented from moving by the pin G. Let the balance be made to vibrate, and the lever F will move through

the arc Ff , strike the inner extremity of the spring, I , and displace the pin G . At this instant the face E , which may be called the pallet, will have arrived at the position e , against which the tooth of the wheel will fall, and communicate its impulse through about 15° or 16° of the vibration. But F quits the spring I sooner than the wheel quits the pallet E , and consequently the pin G will have returned to its first station before the wheel can have advanced a whole tooth, and the spring or detent $H G$ will receive the wheel as before, immediately after its escape from the pallet. The returning vibration of the balance will be made with the piece $E L$ perfectly at liberty between two teeth of the wheel, as in the sketch, and the back stroke of the lever F against the tender spring I will have no effect whatever on the pin G ; this spring being like the back spring of the jacks of the harpsichord, active in one direction only. The third vibration of the balance will unlock the detent as before: the impulse will again be given, and the whole process will be repeated; and in this manner, the balance, though it may vibrate through the greatest part of the entire circle, will be entirely free of the works, except during the very small time of the drop of the wheel.

It is hardly necessary to make any remark on this scapement. It requires little or no oil, and when all the parts, particularly the pendulum spring, are duly adjusted, it is found that a very great variation in the first mover will remarkably alter the arc of vibration without affecting the rate. The piece $E L$ might have consisted of a single pallet or arm, instead of a portion of a circle or cylinder; but such a piece would have been rather less convenient to make in sapphire, or ruby, as in the best time-pieces, and would also have been less useful. For if by any accident or shock, the pin G should be displaced for an instant, the wheel D will not run down, because it will be caught upon the circular surface $E L$. It is, indeed, very easy to observe, that the piece $E L$ would operate without the detent, though with much friction during the time of repose. The tooth of the wheel would in that case rest upon its circular face.

6. In the two last scapements we have seen the variable effects of the maintaining power almost entirely removed, as far as can be practically discerned. Fig. 7, exhibits the scapement of Mudge; in which the balance is perfectly detached from the train of wheels, except during the extremely short interval of striking out the parts which serve the purpose of detents. $O N E B Q$ is the circumference of the balance, vibrating by the action of a spiral spring as usual on its axis $C A D H$ passing through the centre C : the axis is bent into a crank, $A X Y D$, to make room for the other work. $L M, Z W$, are two rods fixed to the crank at the points L and Z , parallel to $X Y$ $c d e f r s$ are fixed parts of the machine. $T R$ is an axis concentric with that of the balance, and carrying an arm $G o$ nearly at right angles to it, and a small auxiliary spring u , which is wound up whenever the arm $G o$ is moved in the direction $o h$. p is a curved pallet fixed to the axis $T R$, which receives the tooth of the balance wheel near the axis. The tooth, proceeding along the curved surface, by the force of the main spring turns the axis and its arm $G o$, and winds up the spring u . A small projection at the extremity of the curved surface of the pallet p prevents the further progress of the tooth, when the arm $o G$ has been turned through an arc $o h$, of about 27° ; and consequently the spring u has been wound up through the same angle or arc, $o G h = 27^\circ$.— $F S$ is another axis exactly similar to $T R$. It carries its arm $I o$, and spring v , and the tooth of the balance-wheel $l m$ winds up the spring v , by acting on the pallet q , and is detained by a projection, after having carried it through an angle of 27° , exactly as in the former case. The arcs passed through by the arms $G o$ and $I o$, and marked in the figure, are also denoted by the same letters on the rim of the balance.

The effect of this scapement may be thus explained: let the balance be in the quiescent state, the main spring being unwound, and the branch or crank in the position represented in the figure. If the quiescent points of the auxiliary springs coincide with that of the balance-spring, the arm $G o$ will just touch the rod $L M$, and in the like manner the arm $I o$ will just touch the rod $W Z$; the two arms $G o$ and $I o$ in this position are parallel to the line $C O$. This position of the balance and auxiliary springs remains as long as the main spring of the ma-

chine continues unwound: but whenever the action of the main spring sets the balance wheel in motion, a tooth thereof meeting with one or other of the pallets p or q , will wind up one of the auxiliary springs; suppose it should be the spring u . The arm $G o$ being carried into the position $G h$, by the force of the balance wheel acting on the pallet p , remains in that position as long as the tooth of the balance-wheel continues locked by the projection at the extremity of the pallet p ; and the balance itself not being at all affected by the motion of the arm $G o$, nor by the winding up of the spring u , remains in its quiescent position; consequently no vibration can take place except by the assistance of some external force to set the balance in motion. Suppose an impulse to be given sufficient to carry it through the semi-arc $O B$, which is about 135° in Mr. Mudge's construction.

The balance, during this motion, carries with it the crank $A X Y D$, and the affixed rods $L M, Z W$. When the balance has described an angle of about $27^\circ =$ the angle $o C A$, or $o G h$, rod $L M$ meets with the arm $G h$, and by turning the axis $T R$, and the pallet p in the direction of the arc $O A$, releases the tooth of the balance wheel from the projection at the extremity of the pallet p : the balance wheel immediately revolves, and the lower tooth meeting with the pallet q , winds up the auxiliary spring v , and carries the arm $I o$ with a circular motion through the angle $o I k$, about 27° , in which position the arm $I o$ remains as long as the tooth of the balance-wheel is locked by the pallet q . While the spring v is winding up through the arc $o k$, the balance describes the remaining part of the semi-arc $k E$, and during this motion the rod $L M$ carries round the arm $G h$, causing it to describe an angle $k C B$, or $k G B$, which is measured by the arc $k B = 108^\circ$. When the balance has arrived at the extremity of the semi-arc $O B = 135^\circ$, the auxiliary spring u will have been wound up through the same angle of 130° , that is to say, 27° , by the force of the main spring acting on the pallet p , and 108° by the balance itself, carrying along with it the arm $G o$ or $G h$, while it describes the arc $k B$. The balance therefore returns through the arc $B O$, by the joint action of the balance-spring and the auxiliary spring u ; the acceleration of both springs ceasing the instant the balance arrives at the quiescent point o . When the balance has proceeded in its vibration about 27° beyond the point O , to the position $C k$, the rod $Z W$ meets with the arm $I k$, and by carrying it forward releases the tooth of the balance-wheel from the pallet q . The balance-wheel accordingly revolves, and the upper tooth meeting with the pallet p winds up the auxiliary spring u as before. The balance with the crank proceeding to describe the remaining semi-arc $k E$, winds up the spring v through the further angle $k C E = 108^\circ$, and returns through the semi-arc $E o$, by the joint action of the balance-spring and the auxiliary spring v , both of which cease to accelerate the balance the instant it has arrived at O .

It may be remarked, in this curious scapement, that the motion of the balance in its semi-vibration from the point of quiescence is opposed through an arc of no more than 108° , but is accelerated in its return through the whole arc of 135° , and that the difference is what maintains the vibrations; and moreover, that the force from the wheel being exerted to wind up each auxiliary spring during the time it is totally disengaged from the balance, this last organ cannot be effected by its irregularities, except so far as they may render it more difficult to disengage the rim of the pallet from the tooth. The balance describes an arc of about 8° during this disengagement.

Count Bruhl, in his pamphlet "On the Investigation of Astronomical Circles," after describing Mudge's scapement, proceeds thus: "By what has been said, it is evident, that whatever inequality there may be in the power derived from the main-spring (provided the latter be sufficient to wind up these little pallet-springs), it can never interfere with the regularity of the balance's motion, but at the instant of unlocking the pallets, which is so instantaneous an operation, and the resistance so exceedingly small, that it cannot possibly amount to any sensible error. The removal of this great obstacle was certainly never so effectually done by any other contrivance, and deserves the highest commendation as a probable means to perfect a portable machine that will measure time correctly. But this is not the only, nor indeed the principal advantage

which this time-keeper will possess over any other; for as it is impossible to reduce friction to so small a quantity as not to affect the motion of a balance, the consequence of which is, that it describes sometimes greater and sometimes smaller arcs, it became necessary to think of some method by which the balance might be brought to describe those different arcs in the same time. If a balance could be made to vibrate without friction or resistance from the medium in which it moves, the more expanding and contracting of the pendulum-spring would probably produce the so much wished for effect, as its force is supposed to be proportional to the arcs described; but as there is no machine void of friction, and as from that cause, the velocity of every balance decreases more rapidly than the spaces gone through decrease, this inequality could only be removed by a force acting on the balance, which assuming different ratios in its different stages, could counterbalance that inequality. This very material and important remedy, Mr. Mudge has effected by the construction of his scapement; for his pallet springs having a force capable of being increased almost at pleasure, at the commencement of every vibration, the proportion in their different degrees of tension may be altered till it answers the intended purpose. This shews how effectually Mr. Mudge's scapement removes the two greatest difficulties that have hitherto baffled the attempts of every other artist, namely, the inequalities of the power derived from the main spring, the irregularities arising from friction, and the variable resistance of the medium in which the balance moves."

7. Fig. 8, is the sketch of an adaptation of Mudge's scapement to a clock. LM is a part of the periphery of the wheel. GA, GB, are two arms separately moveable on the same axis, and terminating in the pallets A, B. These pallets have inclined faces, with a claw or detent at the lower part of each. GO, IO, are tails proceeding from each pallet piece respectively, and the dark spot at N represents a pin proceeding from the pendulum rod, and capable of moving either of the tails according to the course of the vibration. The dotted circles *u* and *v* represent weights which are stuck upon two pins, and may be changed for others, greater or smaller, until the most suitable quantity is found. Suppose the wheel to be urged from L towards M, and the pendulum made to vibrate by external impulse; the pin N proceeding towards L will strike the tail GO, raise the pallet A, and set the wheel at liberty: which sliding along the inner surface of the pallet B, will raise it, and stop against the claw at its lower end. IO will consequently be carried into the position IP; and the pallet A in its return will be opposite to a vacancy, which will permit the tail GO to follow the pin N as far as the perpendicular situation. The pendulum will therefore be assisted by the weight *u* through a longer arc in its descent, than it was impeded by it in its ascent. In the opposite semi-vibration toward M, the pendulum will proceed unopposed by *v*, while it passes through the angle OIP, when it will raise B, and permit the wheel to elevate the pallet A. In the motion on this side of the perpendicular, it is also clear that the descent will be more assisted than the ascent was impeded. Whence it follows, that the clock will continue to go: and no variation of the force of the wheel LM, which raises the pallets in the absence of the pendulum will affect the vibration, except so far as it may afford a variable resistance at the detent or claw.

8. Mr. Mudge has also given another detached scapement, which he recommends for pocket watches, and executed entirely to his satisfaction in one made for the queen. A dead-beat pendulum scapement is interposed between the wheels and the balance. The crutch E D F (fig. 3. has a third arm DG standing outwards from the meeting of the other two, and of twice their length. This arm terminates in a fork AG B. The verge V has a pallet C, which, when all is at rest, would stand between the points A, B, of the fork. But the wheel by its action on the pallet E, forces the fork into the position B g b, the point A of the fork being now where B was before, just touching the cylindrical surface of the verge. The scapement of the crutch E D F is not accurately a dead-beat scapement, but has a very small recoil beyond the angle of impulsion. By this circumstance the branch A (now at B) is made to press most gently on the cylinder, and keeps the wheel locked, while the balance is going round in the direction B H A. The point A gets a motion from A to B by means of a notch in the cylinder, which turns

round at the same time by the action of the branch AG on the pallet C; but A does not touch the cylinder during this motion, the notch leaving free room for its passage. When the balance returns from its excursion, the pallet C strikes on the branch A (still at B), and unlocks the wheel. This now acting on the crutch-pallet F, causes the branch b of the fork to follow the pallet C, and give it a strong impulse in the direction in which it is then moving, causing the balance to make a semi-vibration in the direction A H B. The fork is now in the situation A g a, similar to B g b, and the wheel is again locked on the crutch pallet E.

The intelligent reader will admit this to be a very steady and effective scapement. The lockage of the wheel is procured in a very ingenious manner; and the friction on the cylinder, necessary for effecting this, may be made as small as we please, notwithstanding a very strong action of the wheel; for the pressure of the fork on the cylinder depends entirely on the degree of recoil that is formed on the pallets E and F. Pressure on the cylinder is not indispensably necessary, and the crutch-scapement may be a real dead-beat. But a small recoil, by keeping the fork in contact with the cylinder, gives the most perfect steadiness to the motion. The ingenious inventor, a man of approved integrity and judgment, declares that her majesty's watch was the best pocket-watch he had ever seen. We are not disposed to question its excellency.

9. Another scapement, in which a considerable degree of ingenuity is united with comparative simplicity, is that of Mr. De Lafons. The inventor's description and some of his observations, as presented to the Society of Arts, are as follows:—Although the giving an equal impulse to the balance has been already most ingeniously done by Mr. Mudge and Mr. Halloy (from whose great merit we would not wish to detract,) yet the extreme difficulty and expense attending the first, and the very compound locking of the second, render them far from completing the desired object. The perfections and advantages arising from my improvements on the remontoire detached scapement for chronometers, which gives a perfectly equal impulse to the balance, and not only entirely removes whatever irregularities arise from the different states of fluidity in the oil, from the train of wheels, or from the main spring, but does it in a simpler way than any with which I am acquainted. I trust it will not be thought improper in me to answer some objections made at the examinations before the committee, as I am fully persuaded the more mathematically and critically the improvements are investigated, the more perfect they will prove to be. It was first observed that my method did not so completely detach the train of wheels from the balance as another scapement then referred to. I beg leave to remark, that the train of wheels in mine is prevented from pressing against the locking by the whole power of the remontoire-spring: so that the balance has only to remove the small remaining pressure, which does away that objection, and also that of the disadvantage of detents, as this locking may be compared to a light balance turning on fine pivots, without a pendulum spring; and has not only the advantage of banking safe at two turns of the balance, and of being firmer and less liable to be out of repair than any locking where spring work is used, but likewise of unlocking with much less power.—It was then observed, it required more power to make it go than usual. Permit me to say, it requires no more power than any other remontoire-scapement, as the power is applied in the most mechanical manner possible.—And, lastly, it was said, that it set or required the balance to vibrate an unusually large arch before the piece would go. This depends on the accuracy of the execution, the proportionate diameter and weight of the balance, the strength of the remontoire-spring, and the length of the pallets. If these circumstances are well attended to, it will set but little more than the most generally detached scapements. A, fig. 9, shews the scape wheel; B, the lever-pallet, on an arbor with fine pivots, having at the lower end, C, the remontoire or spiral-spring fixed with a collar and stud, as pendulum-springs are; D the pallet of the verge, having a roller turning in small pivots for the lever pallet to act against; E pallets to discharge the locking, with a roller between, as in fig. 10; F, the arm of the locking-pallet continued at the other end to make it poise, having studs and screws to adjust and bank the quantity of

motion; *a*, and *b*, the locking pallets, being portions of circles fastened on an arbor turning on fine pivots; *G*, the triple fork, at the end of the arm of the locking pallets. The centre of the lever pallet in the draft, is in a right line between the centre of the scape wheel and the centre of the verge, though in the model it is not; but may be made so or not, as best suits the calliper, &c.

The scape-wheel *A*, with the tooth *I*, is acting on the lever-pallet *B*, and has wound up the spring *C*; the verge pallet *D* (turning the way represented by the arrow) the moment it comes within the reach of the lever pallet, the discharging pallet *E*, taking hold of one prong of the fork, removes the arm *F*, and relieves the tooth *p* from the convex part of the lock *a*. The wheel goes forward a little, just sufficient to permit the lever-pallet to pass, while the other end gives the impulse to the balance; the tooth 4 of the wheel is then locked on the concave side of the lock *b*, and the lever-pallet is stopped against the tooth 5, as in fig. 11. So far the operation of giving the impulse, in order again to wind the remontoire spring (the other pallet at *E*, in the return removing the arm *F* the contrary direction), relieves the tooth 3 from the lock *b*. The wheel again goes forward, almost the whole space from tooth to tooth, winds the spiral spring again, and comes into the situation of fig. 1, and thus the whole performance is completed. The end of the lower pallet *B* resting on the point of the tooth 1, prevents the wheel exerting its full force on the lock *a*, as in fig. 1. The same effect is produced by the pallet lying on the tooth 5, by preventing the wheel from pressing on *b*; and thus the locking becomes the tightest possible. This escapement may be much simplified by putting a spring with a pallet made in it as in fig. 12, instead of the lever pallet, and spiral-spring. The operation will be in other respects exactly the same, avoiding the friction of the pivots of the lever-pallet. This method I prefer for a piece to be in a state of rest, as a clock; but the disadvantage from the weight of the spring in different positions, is obvious. The locking may be on any two teeth of the wheel, as may be found most convenient.—*Dr. Gregory's Mechanics.*

Many other ingenious escapements have been contrived by Harrison, Hindley, Ellicott, Lepaute, Le Roy, Berthoud, Arnold, Whitehurst, Earnshaw, Nicholson, &c. But descriptions of them would extend this article to much too great a length. What is here collected will, we trust, furnish some insight into the nature of a few of the most approved escapements.

SCAPHISM, an unseemly torture among the ancient Persians, by which criminals were exposed to be stung to death by wasps.

SCAPOLITE, a mineral found at Arendal in Norway. It is of a pearl colour, and is crystallized in long, four-sided rectangular prisms. Faces longitudinally streaked. Its specific gravity is 3.68, and it is hard enough to scratch glass.

SCARABÆUS, in Natural History, the *Beetle*, a genus of insects of the order coleoptera. In this genus there are several hundred species, in four divisions, which are distinguished by the form of their feelers. The beetle is the most remarkable species, as well in size as in beauty. It is five or six inches long; the wing-shells are of a smooth surface, of a bluish-gray colour, marked with round deep-black spots of different sizes. In this country, the cockchafer is very common. The larva inhabits ploughed lands, and feeds on the roots of corn; and the complete insect makes its appearance during the middle and the decline of summer. The larva of this insect is eagerly sought after and devoured by swine, bats, crows, and poultry; it is said to be two or three years in passing from its first form into that of the perfect insect. A species of great beauty is the golden beetle, about the size of the common or black garden beetle; the colour is most brilliant, varnished, and of a golden green. This is a fine object for the magnifying glass. It is not very uncommon during the hottest parts of summer, frequenting various plants and flowers; its larva is commonly found in the hollows of old trees, or among the loose dry soil at their roots, and sometimes in the earth of ant hills.

SCARFING, a sea term, a particular method of uniting two pieces of timber together by the extremities, so that the end of one goes over the end of the other, being tapered so that the one may be set into the other, and become even, as the keel-pieces. But when the ends of the two pieces are cut square

and put together, they are said to butt to one another, (see the article **BUTT**;) and when another piece is laid on and fastened to both, as is the case in all the frame timbers, this is called scarfing the timbers, and half the piece which fastens the two timbers together is reckoned the length of the scarf.

SCARIFICATION, in Surgery, the operation of making several incisions in the skin by means of lancets, or other instruments, particularly the cupping-instrument.

SCARLET, a beautiful bright red.

SCARP, in Fortification, the interior slope of the ditch with which the fortification is surrounded, and faces the country or campaign.

SCAVAGE, a toll or custom anciently exacted by mayors, sheriffs, and bailiffs of cities and towns-corporate, and of merchant strangers, for wares exposed and offered to sale within their liberties, which was prohibited by 19 Hen. VII. But the city of London still retains this custom.

SCAVENGERS, two officers chosen annually in each parish in London and the suburbs, whose business it is to see that the streets are kept clean, under a penalty of forty shillings for each offence.

SCÉLOTYRBE, a disease characterized principally by a contraction of the limbs. For this, various causes have been assigned.

SCENE, in a primary sense, denotes a theatre, where dramatic pieces, and other public shows, were represented. Its application is now extended to picturesque views of almost every description.

SCENOGRAPHY, in Perspective, the perspective representation of a body on a plane; or a description and view of it in all its parts and dimensions, such as it appears to the eye in any oblique view.

SCENOPEGIA, a grand festival among the Jews, at which all their males of a given age were to attend at their national altar. It is more generally called "the feast of tabernacles."

SCENT, in Hunting, the effluvia thrown off by animals in the chase, and by which they are followed through all their mazes and retreats, by dogs and those who follow them. So acute is the sense of smelling in these hounds, that carcasses buried with lime ten feet under ground, have been known to attract them to the spot. The term scent, in a lax sense, is sometimes applied to things highly offensive to the olfactory nerves, but frequently to aromatics, and agreeable odours.

SCEPTIC, one who embraces scepticism, and sometimes affects to doubt his own existence.

SCEPTICISM, doubt, hesitation, indecision, unbelief. Scepticism professes to weigh every thing, but it determines nothing. It robs the mind of its resting-place, but substitutes nothing in its stead.

SCHEDULE, a scroll of parchment or paper, annexed to a deed, will, or other instrument, containing an inventory of goods, &c. omitted in the body of the will or deed. It is used particularly for the statement of effects delivered by a bankrupt to the commissioners who are appointed to investigate his affairs. It also includes a list of such articles as are the subjects of taxation.

SCHEIK, a name given by the Turks to the prelates of the Mahometan religion, who pretend to be the legitimate successors of Mahomet. Their chief resides at Mecca.

SCHEME, representation of any geometrical or astronomical figure, or problem, by figures sensible to the eye; and also the harmonious result of contrivance and ingenuity.

SCHIECH, in Arabia, an officer of high birth, which can only come by descent, and is peculiar to princes, sovereigns, and independent lords. Among the Bedouins, this title belongs to every noble.

SCHIRROSIS, a name given to a disorder in the eyes, arising from a long continued inflammation, when the flesh increases in bulk, and assumes a livid colour.

SCHISM, literally, a cleft or fissure. In Religion, to which the term is chiefly applied, it means a separation among persons who profess the same general principles of faith, but differ in some subordinate particulars. The Romanists enumerate thirty-four schisms that have taken place in their church, among which, the ecclesiastical revolution that took place in the days of Luther, holds a prominent rank. The Reformation

that took place in this country is called the English schism; and the English church, in its turn, applies the opprobrious epithet to Presbyterians, Independents, Anabaptists, and Methodists; while each of these sects cry out schism against all who secede from their respective communities.

SCHISTUS, in Mineralogy, a name given to several different kinds of stones, but more especially to some of the argillaceous kind.

SCHOLASTIC, something belonging to the schools, or taught in them. Connected with Philosophy, it is a name given to the dialectic of Aristotle. From the fifth until the twelfth century, scholastic philosophy was held in high esteem. The Reformation inflicted on it a deadly wound, so that at present it is little studied, and less regarded.

SCHOLASTICS, persons who study either scholastic philosophy or divinity.

SCHOLIUM, a note, annotation, or remark; occasionally made on some passage or proposition of an old author.

SCHOOL, a public place in which languages, arts, and sciences, are taught. Schools vary in character and degree, according to the subjects introduced, from the elementary principles of words, to the result of academic researches, and the learning inculcated in the most renowned universities. In the management of schools considerable improvements have been made of late years, but more generally in their lower departments. The word *Schola* originally signifies discipline and correction, and it was anciently used to designate all places where persons met together either to study, to converse, or to do any other matter. Among the Hebrews, the synagogues succeeded the schools of the prophets.

The *Charity SCHOOLS* in England are both numerous and opulent, but replete with abuses. Winchester, Eton, and Westminster schools, are royal foundations. All the other grammar schools, as they are termed, are, in fact, charity schools, though of a higher class than the parish schools for the education of our pauper youth.

Sunday SCHOOLS, another species of charity schools, have many advocates, as have also the National Schools; and were they universally adopted, we might expect to see the morality of the nation keep pace with these benevolent institutions. Juvenile offenders, without doubt, are numerous; but our gaols are under no obligations to Sunday Schools for their inmates.

SCHOONER, a small vessel with two masts, whose mainsail and foresail are both suspended by gaffs, like a sloop's mainsail.

SCHORL, a mineral which derives its name from Schorlaw, in Saxony, where by him it was first discovered.

SCIARRI, the matter which runs in burning torrents from the craters of volcanoes.

SCIATHERICUM, a horizontal dial, with a telescope adapted for observing the true time, both by day and by night, to regulate and adjust pendulum clocks, watches, and other time-keepers.

SCIATIC STAY, a strong rope fixed from the main to the foremast heads in merchant ships: when loading or unloading, it serves to sustain a tackle, which travelling upon it, may be shifted over the main or fore hatchways, as occasion requires.

SCIENCE, in Philosophy, a clear and certain knowledge of any thing, founded on demonstration, or self-evident principles.

SCIENCES, *General Enumeration of the.*—**PRINCIPLES** of all things—**ELEMENTS** which these principles originate—**BEINGS** which these elements form—**ORGANS** which these beings develop—**WANTS** which these organs experience—**SIGNS** which these wants excite—**SOCIETIES** which these signs produce—**COUNTRIES** which these societies inhabit—**EARTH** which these countries compose—**PLANETARY SYSTEM** to which this earth belongs. Here the accurate observer will, perhaps, allow the implicit dependence of each succeeding on each preceding head; and if we next shew, that, under these heads, every individual science as naturally arranges itself, he will perhaps also grant, that we have traced the basis of a natural system. We shall, accordingly, place these ten successive and dependent heads in the first column of the following table, and range after each, in the third column, the triple science which it involves.

95-6.

* The subjects of these three lines differ considerably; but under Metaphysics, Physics as here employed, and Mathematics: they are all considered abstractly, and it is in that sense that we apply to them the general term—Principles.

† Extension, Divisibility, &c. are only the first subjects commonly placed under this head. We use the term in a limited sense. It is commonly used in a vague manner.

‡ Including the doctrines of property and money, as well as of population.

SCIENTIFIC, something relating to the pure, sublime sciences, or that abounds in science or knowledge. A work is said to be scientific, when it is founded on the pure reason of the thing, or conducted wholly on their principles.

SCIERIA, a festival kept in Arcadia in honour of Bacchus.

SCILLA, the *Squill*, in Botany, a genus of the monogynia order, in the hexandria class of plants, and in the natural method ranking under the 10th order, coronaria.—22 species.

SCIMPODIUM, an ancient bed or couch, adapted for one person only. It was also used instead of the Lectica, to carry both men and women, not only through the city, but likewise in journeys into the country.

SCINCUS, a species of lizard, sometimes called the Crocodile, and formerly well known in the shops of the druggists as an ingredient in several compositions.

SCIOPTIC BALL, a sphere or globe of wood, with a circular hole or perforation, in which a lens is placed. It is so contrived, that, like the eye of an animal, it may be turned round every way, and is used for making experiments in darkened rooms.

SCIRE FACIAS, is a judicial writ, and properly lies after a year and a day after judgment given; whereby the sheriff is

commanded to summon or give notice to the defendant, that he appear and show cause why the plaintiff should not have execution. 1 Inst. 290.

SCIRRUS, in Surgery, a term that denotes any kind of swelling, accompanied with considerable hardness.

SCIRONES, a species of small lice bred under the skin.

SCIRROPHORION, the last month of the Athenian year. It contained twenty-nine days, and corresponded with the latter part of our May and beginning of June.

SCITAMINEA, in Botany, an important order of plants, the eighth among the Fragmenta of Linnæus.

SCIURUS, the *Squirrel*, in Natural History, a genus of mammalia, of the order gillires. These animals live principally on seeds and fruits. They are extremely active and nimble, climbing trees with great rapidity, and bounding from one to another with a spring truly astonishing. Some are supplied with membranes, which enable them to extend this leap into something approximating to a short flight. Some are subterraneous, and others build in trees. They are sprightly, elegant, and interesting. The sailing squirrel is an inhabitant of Java and the Indian islands, and can spring to an immense distance from tree to tree, by means of a membrane similar to that of the preceding, which is extremely thin in the middle, and thicker towards the extremities. This is the largest of all the flying squirrels, and is eighteen inches long, exclusively of the tail.

SCLEROTICA, in Anatomy, one of the tunics, or coats of the eye.

SCNIPS, a small species of gnat found about the oak, and sustained by the juices of its leaves.

SCOBBS, the raspings of ivory, hartshorn, or other hard substances.

SCOLD, COMMON, a turbulent woman, liable to be indicted, and punished as a public nuisance. In the Saxon laws this punishment was the cucking-stool, now corrupted into the ducking stool.

SCOLEX, a genus of the Vermes intestina class and order.

SCOLIA, a genus of insects of the order hymenoptera.

SCOLIA, songs of the ancient Greeks.

SCOLOPAX, the *Curlew*, in Natural History, a genus of birds of the order grillæ. There are fifty species, of which the following are the chief: The common curlew, generally about two feet long, is to be met with in England throughout the year, either on the coasts or near the mountains. Slugs and worms, which its bill extracts from the ground in the morning and evening, constitute its inland subsistence; and when on the shores of the sea, it feeds on marine animals. These birds are often observed in large flocks, and are used by many for food. Those killed on the coasts, however, are rank and fishy.—The woodcock is about fourteen inches in length, migratory in this country, and supposed to proceed from Sweden.—The snipe, weighs about four ounces, is about twelve inches long, and to be found in nearly every country of the world. Its food consists of worms and insects, which it seeks near small streamlets and in general in wet grounds.—The common godwit, is of the weight of twelve ounces, and ranks in the highest order of delicacies.—The redshank, is not uncommon in this island, and particularly towards the south.

SCOLOPENDRA, in Natural History, centipede, a genus of insects of the order aptera. There are thirteen species found in almost all parts of the world; they live in decayed wood, or under stones, and some of them in fresh and salt water; they prey on other insects. The larger species are found only in the hotter regions of the globe; they are insects of a terrific appearance, and possess the power of inflicting severe pain and inflammation by their bite.

SCOMBER, the *Mackerel*, in Natural History, a genus of fishes of the order thoraci. There are twenty-one species, of which we shall notice the following:—The common mackerel. This is one of the most beautiful of fishes, and inhabits both the European and American seas. The mackerel is a fish highly admired both for its beauty and excellence, and has in every age attracted particular notice and partiality from both these circumstances. The Romans prepared from it a condiment of essence for the table, which was in the highest estimation. The general length of this fish is fifteen inches, but specimens far larger have been occasionally met with.—The tunny is some-

times ten feet long, and on the Scotch coast one was taken which weighed four hundred and sixty pounds. In the Indian ocean it is said to exceed even this enormous size. These fishes are not particularly admired for food in this country, in which, indeed they are rarely seen approaching the British coast only in straggling parties, or rather as solitary individuals. By the ancients, fisheries were established for taking and preserving them, on the coasts of the Mediterranean, in which sea they particularly abound, and there are at present on the same coasts very extensive establishments for this purpose. Indeed, to the inhabitants on those shores, the movements of tunny are watched and expected with as much eagerness as those of the herring or mackerel in the north. The small fishes are generally carried fresh to market, and the large ones are cut up into pieces of a particular size, and preserved in salt in barrels. The tunny is a very voracious fish, and a great persecutor of the common mackerel.

SCOOP, a little hollowed piece of wood employed to throw the water out of a boat, which operation is usually called baling the boat.

SCORE, in Music, the original and entire draught, or its transcript, of any composition.

SCORIA, or *Dross*, is that mass which is produced by melting metals and ores, and when cold is brittle, and not insoluble in water; being properly a kind of glass.

SCORING, the art of forming a score by collecting, and properly arranging under each other, the several detached parts of any composition.

SCORPIO, the *Scorpion*, π , is the eighth sign in the order of the zodiac, and the second of the southern signs. The sun enters it on the 23d of October, according to the fixed and intellectual zodiac of Hipparchus and the moderns; but if we follow this sign in the recession of Aries and his train, we shall find that the sun enters Scorpio about the 20th of November. The ancient poets of Greece tell us, that this is the *Scorpion* which Diana sent to wound Orion for usurping her office. Ovid tells us, that this serpent was produced by the earth, to punish Orion's vanity for having boasted that there was not on the terraqueous globe any animal which he could not conquer. Again, it is said that Autumn, which produces fruits in great abundance, brings with it a variety of diseases; and this season is very fitly represented by a *Scorpion*, which wounds with its tail as it recedes.

Boundaries and Contents.—Scorpio is bounded on the north by Serpentarius and Serpens; east by Sagittarius; south by Lupus, Norma, and Ara; and west by Libra: but the tail of Scorpius does not rise at London. In this sign there are forty-four stars, of which, one is of the first magnitude, one of the second, eleven of the third, eighth of the fourth, &c. *Antares*, called also *Cor Scorpii*, of the first magnitude, rises on the south-east point of the horizon at London. Its declination is $26^{\circ} 1' 10''$ south; its right ascension $244^{\circ} 35' 36''$; and it rises and culminates as in the following table: Meridian altitude $12^{\circ} 27' 50''$.

MONTH.	RISES. ho. mi.	CULM. ho. mi.	MONTH.	RISES. ho. mi.	CULM. ho. mi.

SCORPIO, in Natural History, a genus of insects of the order Aptera. There are ten species, all of which are armed with a slightly pungent sting; and in hot climates some of them are highly dangerous: they prey upon worms, spiders, flies, &c. and even on one another.

SCORPION, in the ancient art of war, an engine chiefly used in the defence of the walls of fortified places by throwing arrows, fireballs, or great stones.

SCOT, a customary contribution laid upon all subjects according to their abilities. Whoever were assessed to any contribution, though not by equal portions, were said to pay scot and lot.

SCOTCH FIR, common fir, or pine tree.

SCOTCHES, in Agriculture, a term signifying scores or notches. It is sometimes employed as a mode of reckoning, by farmers.

SCOTES, a species of duck, sometimes called the black diver. **SCOTIA**, in Architecture, a semi-circular cavity or channel, between the torcs in the bases of columns.

SCOTISTS, a sect of school divines and philosophers, so called from J. Duns Scotus, their founder, who flourished in the fourteenth century, but they are now unknown.

SCOTLAND. By 5 Anne, c. 8, the Union of England and Scotland was effected, and the twenty-five articles of union, agreed to by the parliaments of both nations, were ratified and confirmed as follows: viz. the succession to the monarchy of Great Britain shall be the same as before settled with regard to that of England. The united kingdoms shall be represented by one parliament. There shall be a communication of all rights and privileges between the subjects of both kingdoms, except where it is otherwise agreed. When England raises £2,000,000 by land-tax, Scotland shall raise £48,000. The standards of the coin, of weights and measures, shall be reduced to those of England throughout the united kingdoms. The laws relating to trade, customs, and excise, shall be the same in Scotland as in England. But all the other laws of Scotland shall remain in force, though alterable by the parliament of Great Britain; and particularly, laws relating to public policy are alterable at the discretion of parliament. Laws relating to private right are not to be altered, but for the evident utility of the people of Scotland. Sixteen peers are to be chosen to represent the peerage of Scotland in parliament, and forty-five members to sit in the house of commons. The sixteen peers of Scotland shall have all privileges of parliament, and all peers of Scotland shall be peers of Great Britain, ranking next after those of the same degree at the time of the union, and shall have all privileges of peers, except sitting in the house of lords, and voting on the trial of a peer.—It was formerly resolved by the house of lords, that a peer of Scotland, claiming and having a right to sit in the British house of peers, had no right to vote in the election of the sixteen Scotch peers; and that if any of the sixteen Scotch peers are created peers of Great Britain, they thereby cease to sit as representatives of the Scotch peerage, and new Scotch peers must be elected in their room.

SCOUR, in Military language, is to flank a line in such a manner as to go directly along it, so that a musket ball, entering at one end, may reach to the other, leaving no place of security.

SCOURING, among cattle, is a disease of the flux kind, which frequently proves mortal. Sheep are not exempt from its influence. Scouring, among Farriers, is a gentle purge, to preserve animals from noxious humours.

SCOUTS, in Military language, are generally horsemen sent out either before, or on the wings of an army, at the distance of a mile or two, to discover the enemy, and give some signal of alarm.

SCRAPER, an instrument used in mezzotinto engraving, formed much in the manner of a knife, except towards the point, where it slopes off at an angle from both sides. In common language, the application of the term to numerous utensils is well known.

SCRAPER, *Shipcarpenter's*, is an iron machine, having two or three sharp edges, used to scrape off the dirty surface of the planks on a ship's side, or decks, or to clean the topmasts, &c. When the sides of a ship are thus sufficiently scraped, they are varnished over with turpentine, or a mixture of tar and oil, &c. which prevents the planks from being rent or split by the sun or wind.

SCRATCH, the name of a calcareous, earthy, or stony substance, which separates it from sea water in boiling it for salt. This concretion, which forms itself on the sides and bottoms of the pans to which it adheres, is the same substance that crusts over the inside of our tea-kettles. It is a species of spar sustained more or less in all water, from which it is detached by boiling.

SCRATCHES, a disease in horses, consisting of dry chops, scabs, or rifts, that are generated between the heel and the pastern joint.

SCRATCH Work, a way of painting in fresco. It is rough, but lasting, and is chiefly used to embellish the fronts of magnificent buildings.

SCREEN, in domestic comfort, an instrument for keeping off the wind, or the excessive heat of the fire. In Building, *Screen* is used as a frame of laths, for sifting earth, lime, or sand. In Agriculture, *Screen*, among farmers, is a contrivance made chiefly of wires in a frame, for the purpose of separating grain of various kinds from seeds of weeds with which it was previously mixed.

SCREEN, is the name given to the pieces of canvass, or hammock, hung round a birth for warmth and privacy.

SCREW, one of the mechanical powers. See **MECHANICAL Power**.

Machine for Making an original and perfect Screw.—This machine was invented by Mr. Angus Mackinnon, Glasgow. Fig. 1 is a plan, and fig. 2 is an end view of the machine for constructing the screw. AA is the cast-iron bar, upon which

Fig. 1.

the die-frame BB is made to move; cccc, two strong springs attached to the die-frame, having rollers, dddd, in each end, moving upon the angular parallel edges of the bar AA. E, a small frame for holding the cutter; the cover being removed, to shew the action of the cutter upon the steel cylinder, of which the screw is to be made. F, the steel cylinder; the point of the cutter, (which must be adjusted to an angle, varying according to the pitch of thread wanted,) is seen projecting from the

FIG. 2.

frame E, being pressed forward by the screw G. One end of the cylinder F acts upon the centre in the head-stock I. The journal upon the other end of the cylinder works into the steel collar V. A A A A, four small screws for pressing forward the springs cccc. I I I I, four small eyes in the die-frame, to which cords are attached, passing over the pulleys m m m m; weights

being hooked on at the other ends of the cords, sufficient to overcome the friction of the die-frame. N, the handle to turn the cylinder.

In beginning to make the screw, the two weights to the left are hooked on to the ends of the cords, and the cylinder is turned round by the handle, until the cutter traverses the length of the cylinder, when the weights are removed to the cords on the right hand. By continuing this operation alternately from right to left, an original and perfect screw is produced, as exhibited in fig. 3. In the end view of the machine, fig. 2, *o o* represents one of the feet by which it is fastened to a bench. The same letters refer to the same parts of the machine in both figures, where those parts are exhibited. Having obtained, as already described, one screwed cylinder; this is removed, and another of the same size is put into the machine. The same operation is performed on it as on the last; but it is not screwed to a full thread, the sharp cutter being removed when the spaces and threads are of an equal size, and a square cutter is put in its place, by means of which is obtained what is technically termed a square thread, as shown in fig. 4. In the same manner, a third and a fourth cylinder are screwed, each being successively a degree smaller than the preceding. The small frame holding the cutter is now removed, and replaced with dies, a set of which is to be screwed with each of the above cylinders. When the dies are to be screwed, they are placed in the die-frame with one of the cylinders already made, and pressed against it by the screws *G g*, until they are fully screwed. After this, they are replaced with another cylinder, and another set of dies, which are likewise to be screwed. The same operation is performed with a third and a fourth set; (the first set of dies *only*, having a sharp thread, the other set having square threads,) after which they are to be tempered. The headstock is now removed to the left, to admit the cylinder of which the perfect screw is to be formed, and fastened at any required distance, the machine being constructed to cut a screw above three feet in length. The cylinder being placed

between the sharp dies, which are gently pressed by the screws *G g*, is turned round by the handle, until the die-frame reaches the left hand of the cylinder; it is then turned in the contrary way, and worked in the same manner as when using the cutter. When a square-thread screw is to be made, the sharp dies must be removed after the indentation is sufficiently deep to admit the square dies, which are to be substituted for the former; when these have cut the screw to a considerable depth, a smaller set of square dies is taken in succession, until the screw is finished.

N. B. Figs. 7 and 8 represent a small stock made of steel, and hardened, for holding the cutter while sharpening. Figs. 9 and 10 represent an edge and side view of the cutter. Figs. 5 and 6 represent the dies.

SCRIBE, a principal officer in the Jewish law, whose business it was to write and interpret scripture.

SCRIBING, in Joinery, the joining two pieces of wood together, when the surfaces are irregular, so that the protuberances in the one part shall suit with exactness the indentations of the other.

SCRIPTURE WRITING, the revelation of God to man, as contained in the Bible. All profane scoffing at the holy scripture, or exposing any part thereof to contempt or ridicule, is punishable by fine and imprisonment. 1 Haw. 7.

SCRIVENER, one who lends money out at interest. Also, one who transacts money matters between contracting parties.

SCROFULA, a disease commonly called the *king's evil*. The name *scrofula* was derived from an opinion that swine were particularly subject to this affliction.

SCROLL, in Heraldry, is the ornament placed under the escutcheon, containing a motto or short sentence, alluding sometimes to the bearings, or the bearer's name; sometimes expressing somewhat that is divine or heroic, and sometimes what may be deemed heroic.

SCRUPLE, a weight equal to the third part of a drachm, or to twenty grains.

SCRUTORE, or **SCRUTOIRE**, a kind of cabinet, with a door or lid opening downward, for the convenience of writing.

SCUD, a name given by seamen to the low and thin clouds which are most swiftly wafted along by the wind in dull weather.

SCUDDING, the movement by which a ship is carried precipitately before a tempest, and is either performed with a sail extended on her foremast, or, if the storm is excessive, without any sail, which is then called, *scudding under bare poles*. In sloops and schooners, and other small vessels, the sail employed for this purpose is called the square-sail. In large ships it is either the foresail at large, reefed, or with its goosewings extended, according to the degree of the tempest; or it is the fore-top-sail close reefed, and lowered on the cap, which last is particularly used when the sea runs so high as to become the foresail occasionally, a circumstance which exposes the ship to the danger of broaching-to. As a ship flies with amazing rapidity through the water whenever this expedient is put in practice, it is never attempted in a contrary wind, unless when her condition renders her incapable of sustaining the mutual efforts of the wind and waves any longer on her side, without being exposed to the most imminent danger. The hazards to which this operation subjects a vessel are,—a *pooping sea*, the difficulty of steering to prevent broaching-to, and the want of sufficient sea-room. A sea striking the ship violently, may dash it inwards, by which she must inevitably founder; in broaching-to suddenly, she is threatened with being immediately overset; and for want of sea-room, she is endangered by shipwreck on a lee-shore.

SCULL, among sailors, a kind of short oar, the loom of which is only equal in length to half the breadth of the boat, whereby two may be managed by one man, one on each side. *To Scull*, is to cause a boat to advance by a particular method of managing a single oar over the boat's stern.

SCULLER, a term denoting a boat rowed by one man with two short oars, or rather sculls; it is used in contradistinction to *OARS*, which signifies a boat rowed by two men with oars.

SCULPONE, among the Romans, a kind of shoes worn by slaves. They were hollow blocks of wood, like French sabots.

SCULPTURE, is an art, in which, by means of taking away, or adding to matter, all sorts of figures are formed, either in clay or wax, wood, marble, or other stones, or metal. The art of sculpture, in its most extensive sense, comprehends not only carving in wood, stone, or marble, but also enclaving, engraving in all its kinds, and casting in bronze, or lead, wax, and plaster of Paris, as well as modelling in clay, wax, or stucco.

SCUM, a light excrement arising from liquors when briskly stirred; also called foam, froth, or spume. Scum is also used for the impurities which a liquor by boiling casts up to the surface, and likewise for those taken from metals in a state of fusion. These are also called *tutty* and *scoria*.

SCUMA, the scales of any metal, and particularly applied to the small flakes flying off from hot iron under the hammer.

SCUPPERS, certain channels cut through the water-ways and sides of a ship at proper distances, and lined with sheet-lead, in order to carry the water off the deck into the sea.

SCUPPER-HOSE, a leathern pipe or tube nailed round the outside of the scuppers of the lower decks, and which by hanging down prevents the water from entering when the ship inclines under a pressure of sail. *Scupper-Nails*, have very broad heads, so as to retain a great quantity of the hose under them. *Scupper-Plugs*, are used to stop the scuppers occasionally.

SCURF, small exfoliations of the skin which occur after a slight inflammation, and when a new exterior of skin is forming under that which is thrown off.

SCURRA, an ancient name given to the jackdaw.

SCURVY, a formidable and often fatal disease, arising from salt provisions, imperfect nutrition, and other causes. Seamen, during long voyages, are particularly subject to it; but it is also an endemic of the land. Some have thought that it has an affinity to the leprosy, the degree depending on climate, &c.

SCUTAGE was anciently a tax imposed on such as held lands, &c. by knight's service, towards furnishing the king's army.

SCUTARIUS, among the Romans, a shield-maker; also it denotes a life-guard of the emperor, because his body was covered with armour.

SCUTTLE, in Agriculture, a shallow basket used in barns and in stables for various purposes. The sizes are indefinite.

SCUTTLE, a small hatchway, or hole, cut for some particular purpose through a ship's decks or sides, or through the coverings of her hatchways, and furnished with a lid which firmly encloses it when necessary.

SCUTTLING, the act of cutting large holes through the bottom, sides, or decks of a ship, for various occasions, particularly when she is stranded or overset, and continues to float on the surface, in order to take out the whole or part of the cargo, provisions, stores, &c. *To Scuttle a Ship*, to sink her by making holes through her bottom.

SCUTTLE-BUTT, or **CASK**, is a cask having a square piece sawn out of its bilge, and lashed upon the deck. It is used to contain the fresh water for daily use, whence it is dipped out with a leaden can.

SCUTUM SOBIESKI, or **SOBIESKI'S Shield**, a constellation formed by Hevelius: the stars are seven; but four of these are enumerated in the *Aquila*, in the *Britannic* catalogue.

SCYBOLA, in Medicine, a name given to the contents of the bowels when hard, dry, and formed into small masses resembling the excrement of sheep.

SCYPHUS, among the Romans, a very large drinking cup, which was sometimes called the cup of Hercules.

SCYRA, a fine imposed on such as neglected to attend the *Soyregemot* courts, which all tenants were bound to do.

SCYREGE MOT COURT, a county court, anciently held twice a year, by the bishop of the diocese and the alderman or sheriff, in which both the ecclesiastical and temporal laws were given in charge to the county.

SCYTHE, **SITH**, or **Sythe**, an edge-tool used in mowing, being a crooked blade joined nearly at right angles to a long pole or handle. This instrument is well known, and universally valued.

SEA, is a great collection of water; by sailors, however, this word is variously applied to a single wave, to the agitation produced by a multitude of waves in a tempest, or to their particular progress or direction. Thus they say, we shipped a heavy sea—there is a great sea in the offing—the sea sets to the southward. Hence also a ship is said to head the sea when her course is opposed to the setting or direction of the surges. *A long Sea*, implies a uniform and steady motion of long and extensive waves. *A short Sea*, is when they run irregularly, broken, and interrupted, so as frequently to break over a vessel's bow, side, or quarter.

SEA-Boat, a vessel that bears the sea firmly, without labouring heavily, or straining her masts, or rigging. *Sea-Breeze*, the current of air which blows during the day from the sea upon the shore in warm climates. *Sea-Clothes*, are jackets, trowsers, &c. *Sea-Coast*, the shore of any country, or that part which is washed by the sea. *Sea-Legs*, implies the capacity of walking on a ship's decks when she pitches or rolls about at sea.

SEA Kale, the common name of a highly nutritious and palatable vegetable, now much cultivated, and greatly esteemed.

SEA-Mark, a point or conspicuous object distinguished at sea; they are of various kinds, as promontories, steeples, ruins, trees, &c. and are very beneficial by informing vessels of their situation on the coast.

SEA-Port, a haven near the sea, as distinguished from one which is situated up a river.

SEA-Room, implies a sufficient distance from land, rocks, or shoals, wherein a ship may drive without danger of shipwreck.

SEA-Salt, muriate of soda.

SEA-Weed, a sort of herb or tangles floating on the surface of the sea, or washed upon the sea-coast.

SEAL, a puncheon, or piece of metal, or other matter, usually either round or oval, whereon are engraven the arms, device, &c. of some prince, state, community, magistrate, or private person, often with a legend or subscription, the impression whereof in wax, serves to make acts, instruments, &c. authentic. Before the time of William the Conqueror, the makers of all deeds only subscribed their names, adding the sign of the cross, and a great number of witnesses; but that monarch and the nobility used seals with their arms on them, which example was afterwards followed by others. The colour of the wax wherewith this king's grants were sealed was usually green, to signify that the act continued fresh for ever, and of force. A seal is absolutely necessary in respect of deeds, because the sealing of them makes persons parties thereto, and without being sealed they are void in law.

SEALER, an officer in chancery, appointed by the lord chancellor, or keeper of the great seal, to seal the writs and instruments there made in his presence.

SEALING, in Architecture, the fixing a piece of wood or iron in a wall with plaister, mortar, cement, lead, and other solid binding.

SEAM, or **SEME**, of corn, is a measure of eight bushels.

SEAM of Glass, the quantity of 120 pounds, or 24 stones, each five pounds weight. The seam of wood is a horse-load.

SEAMAN, or **SEAFARING-MAN**, a person trained to the occupation of a mariner or sailor. The principal articles required in a common sailor are, that he should be able to steer, to sound, and to manage the sails, by setting, reefing or furling them; he is then called an able seaman.

SEAMEN, in Law: by various statutes, sailors having served the king for a limited time, are free to use any trade or profession, in any town of the kingdom. By 2 George II. c. 36, made perpetual by 2 George III. c. 31, no master of any vessel shall carry to sea any seaman, his own apprentice excepted, without first entering into an agreement with such seaman for his wages; such agreement to be made in writing, and to declare what wages such seaman is to receive during the whole of the voyage, or for such time as shall be therein agreed upon; and such agreement shall also express the voyage for which such seaman was shipped to perform the same, under a penalty of £10 for each mariner carried to sea without such agreement, to be forfeited by the master to the use of Greenwich Hospital. This agreement is to be signed by each mariner within three days after entering on board such ship, and is, when executed, binding on all parties.

SEAMS, the intervals between the edges of the planks in the decks and sides of a ship, or the places where the planks join together; these are always filled with a quantity of oakum, and covered with pitch, to prevent the entrance of the water. *Seam* also implies that part where two edges of canvass are laid over each other and sewed down.

SEARCH WARRANT, in Law, a kind of general warrant issued by justices of the peace, for searching all suspected places for stolen goods. Proper grounds, however, must be shewn for suspicion, before the warrant can be obtained. The name and place also must be specified, general warrants having long since been declared illegal.

SEARCHER, an officer of the customs, whose business it is to search and examine all ships outward bound, to see whether they have any prohibited or uncustomed goods on board.

SEASONINGS, in the West Indies, a kind of ague which strangers endure on their coming to the islands.

SEASONS, in Cosmography, contain portions of the year distinguished by the signs of the zodiac which the sun enters. Spring, summer, autumn, and winter, are their general denominations.

SEASONS, *Terrestrial Globe, for Illustrating the*.—This terrestrial globe, mounted on a new principle, the invention of Mr. Christie, a teacher of mathematics, is so constructed as familiarly to illustrate the earth's annual and diurnal motions, the diversity of the seasons, the sun's apparent progress in the ecliptic, his increase and decrease of declination, and the comparative lengths of days and nights at different times of the year on the same part of the earth, and at the same time of the year on different parts of the earth; as well as to solve all the problems usually performed on a terrestrial globe. Scarcely a

school, or a private family where there are children to instruct, is without a pair of globes; on the use of which different writers have proposed many problems, which, though simple in themselves, have often become very difficult to learners, from the inadequacy of the common globes to illustrate them. Among these are the greater part, if not all those relating to the sun and earth jointly. Many of the difficulties have probably arisen from the inconsistency of representing a place in motion while its horizon is at rest, which has hitherto been done by globe-makers. To remedy this, some writers have recommended the pole to be elevated as many degrees above the horizon as are equal to the sun's declination, instead of the latitude of the place. But this plan is also defective in some particulars; for, what the learner was taught to call the horizon, and what the author at the very time calls the horizon, ceases to be so when the pole is elevated for the sun's declination: besides, the change in the length of days and nights is, by this method, represented to arise from the alternate motion of the poles backwards and forwards with respect to the sun. To a terrestrial globe, the geographer owes his first correct notion of the earth's form; of the relative sizes and situations of places on its surface; of its natural divisions into continents and islands, oceans and seas; and of its artificial divisions into empires, kingdoms, states, and provinces; and when mounted on this plan, it will greatly assist the teachers of astronomy in illustrating the motion of a planet about the sun.

The inventor was led to this discovery by having frequently found considerable difficulty in giving to his younger pupils correct notions of the earth's annual motion, and the consequent phenomena; nor does it appear that others have found the common globes sufficient for this purpose. Ferguson and Bonnycastle recommended a wire circle to be held or fixed in an oblique position, a candle to be placed in the centre, and a small globe suspended by a twisted thread to be carried round the wire circle by the hand. The untwisting of the thread is intended to represent the earth's diurnal, and the progress along the wire its annual motion. Keith sometimes employs the same method, but says, that it "does not so clearly shew the obliquity of the earth's axis to the plane of its orbit," as one which he describes in his *Treatise on the Use of the Globes*.

The apparatus contrived by Mr. Christie fully supplies these deficiencies; exhibiting a clear and intelligible view of the earth's passing through one side of the zodiac while the sun appears to pass through the opposite. It is neither so complicated nor so expensive as to prevent its being generally introduced, and it will greatly facilitate the pupil's progress in what is called the *use of the globes*. Subjoined is a description of the engraving which will be found in the plate of *Artificial Globes, Celestial and Terrestrial*, fig. 8.

The chief novelties of this mounting are, a lamp covered by a hollow sphere of ground glass, representing the sun, round which a terrestrial globe moves, in a circle, whose plane makes with the horizon an angle of $23\frac{1}{2}^{\circ}$; two parallel levers, supporting the globe, and its counterpoise P; an horizon, *h h*, and a meridian, *i m*, both turning with it on its axis: a terminator, *t r*, distinguishing the parts of the earth enlightened from those in darkness; and a claw-foot pillar or stand, T, supporting the whole. Into the top of the stand, a piece of strong steel wire, *w*, is screwed, and its upper end is bent $23\frac{1}{2}^{\circ}$ from the perpendicular, corresponding with the inclination of the earth's axis to the plane of its orbit. On the bent part of the wire is fitted a brass collar, (but invisible in the engraving,) from the opposite sides of which two points extend about an inch: these points move in centres fixed in the upper lever; and this motion permits the same side of the lever to continue upwards, while its ends are alternately elevated and depressed by the motion of the collar on the bent wire. The lower lever moves freely on the wire immediately under the bent part. The levers are connected at their ends by two pieces of brass, each piece having two square holes in it, to admit the ends of the levers. Into the opposite sides of each hole are screwed two steel points which move in centres, permitting the connecting pieces to continue perpendicular, while they are elevated and depressed with the ends of the levers. On the top of the piece connecting the long ends is screwed a brass tube, *a b*, containing the axis of a terrestrial globe, produced and sharpened to a conical point

(at *b*), on which it rests and turns. On the lower end of the other connecting piece is screwed a leaden weight P, which balances the globe, and preserves the parallelism of its axis during its annual motion. On the top of the bent wire is fixed a circular board *d c*, on which are delineated the signs of the zodiac, days of the month, &c.; the board declines $23\frac{1}{2}^{\circ}$ from the level, representing a portion of the plane of the earth's orbit; and a pointer, *c*, from the brass collar, moves with the levers along the circles of signs and months, shewing the sun's place or day of the month, corresponding with any position of the globe, or the position of the globe corresponding with any place of the sun or day of the month. A silk line extends round the circumference of this board and round a pulley on the axis of the globe, at *b*, to produce the diurnal motion; the line is conveyed from the board to the axis through a brass tube *b d*, and after passing the pulley on the axis, it is carried round another pulley, (near *b*), which being fixed to the end of the upper lever, preserves an equal tension on the line. Into the board immediately over the centre of motion of the levers, is screwed a stem supporting a lamp, with its ground glass cover. The remaining parts, viz. the hour circle, the meridian, the horizon, and the terminator, are more immediately connected with the globe. The hour circle, *e o*, is fitted on the axis below the globe, sufficiently stiff to preserve its adjustment, when set to the meridian of any place. The hour is indicated on it by a pointer, (at *o*), attached to the brass tube, *a*. The meridian is a ring of brass attached to the poles, with its flat surface towards the globe; one semicircle of it is divided into degrees, and numbered from the equator towards the poles, for finding the latitudes of places, declination of the sun, &c. The horizon is a thin slip of brass, one end of which fits into a socket fixed on the other: it is attached to a wire which moves up or down with it in a groove near the edge of the meridian, representing at pleasure the rational horizon of any place; and it is divided into degrees and points of the compass, for finding the sun's azimuth, amplitude, &c.; it is necessary to separate the ends of the horizon when it is changed from N. to S. or from S. to N. latitude. Both meridian and horizon are turned with the globe on its axis, so that, when they are adjusted to the latitude and longitude of any place, they retain their adjustment till an alteration is required. In the pole of the horizon, a pointer, *i*, is fixed on the wire, shewing the zenith, to which a quadrant of altitude is occasionally attached. The terminator is sufficiently large to permit the globe with the other circle to turn within it; this circle is made a little concave, to reflect light on those parts which receive but little of the direct light, and to mark more distinctly the difference between the light and dark hemispheres; it is supported by two pivots, (one of which is seen at *r*), fixed in its opposite sides, even with the equator: these pivots are fitted into and move in the ends of a strong semicircular wire, *r a*, which is supported behind the globe with a very strong piece of bent wire, *n a*, extending from the brass tube containing the axis; and the lower part of the terminator is cut, to permit its passing the axis at the south pole, which it does when the sun's declination changes from north to south, or from south to north. From this lower part a circular wire, *o s*, extends 90° upwards, on the top of which is fixed a pointer, *s*, representing a central ray from the sun: this pointer shews the sun's declination, azimuth, amplitude, altitude, and the place where he is vertical at a given time: from the top, a similar wire *f g*, extends 90° downwards behind the globe, where it is attached by a vertical piece, *g k*, to the upper lever produced; the lower end of the vertical wire is the same distance from the piece connecting the levers as its upper end is from the centre of the globe; thus forming a kind of parallelogram, which in some positions of the globe takes the form of a rectangle, and in others that of a rhomboid. This contrivance preserves the face of the terminator constantly towards the lamp, and alternately exposes to its light the north and south poles during its annual motion.

Illustrations.—To illustrate the earth's annual and diurnal motions, nothing more is necessary than to move the pointer slowly along the circles of months and signs, and the globe will be perceived to descend $23\frac{1}{2}^{\circ}$ below the level of the sun on one side, and to rise as many degrees above his level on the other, while the axis remains perpendicular to the horizon, or parallel to itself—the globe at the same time turns on its axis

from W. to E. representing the diurnal motion. During the annual motion, it will be perceived that, when the pointer is at the first degree of Aries on 21st March, the light extends from pole to pole; that all places continue equal portions of time in the light and dark hemispheres; that a straight line joining the centres of the sun and earth would pass through the equator, and consequently the sun has no declination; and that the central ray is crossing the equator from south to north. From this time the earth will be seen gradually descending below the level of the sun, and the central ray gradually rising north of the equator till it reaches the tropic of Cancer, while the pointer, *c*, has passed through Aries, Taurus, Gemini, and reached the first of Cancer on the 21st of June; when it will be perceived that a straight line joining the centres of the sun and earth would pass through the tropic of Cancer, and consequently the sun's declination is $23\frac{1}{2}^{\circ}$ north; that his light extends $23\frac{1}{2}^{\circ}$ over the north pole, but does not reach the south by the same number of degrees; that the diurnal motion does not remove from his light any part of the north frigid; and that all places in north latitude will have their days longer than their nights, while all places in south latitude will have the reverse.

From this period the earth will be seen gradually rising towards the level of the sun, and the central ray descending till it again reaches the equator, during which time the pointer, *c*, will be seen passing through Cancer, Leo, and Virgo, till it reaches the first of Libra on the 23d of September, when the observations which were made on the 21st of March will apply, except that the central ray will now be seen crossing the equator from north to south. From this time the earth will be seen gradually ascending above the level of the sun, while the pointer, *c*, passes through Libra, Scorpio, and Sagittarius, till it reaches the first of Capricornus, when the central ray will have descended to the tropic of Capricornus on the 21st of December. It will now be perceived that a straight line joining the centres of the sun and earth, would pass through the tropic of Capricornus; that the sun's declination is $23\frac{1}{2}^{\circ}$ south; that his light extends $23\frac{1}{2}^{\circ}$ over the south pole, but does not reach the north by the same number; that the earth's diurnal motion does not expose to his light any portion of the north frigid zone, nor remove from it any portion of the south frigid zone; and that all places in the southern hemisphere have longer days than nights, while all places in the northern hemispheres have the reverse. From this time the earth will be seen gradually descending again, while the pointer, *c*, passes through Capricornus, Aquarius, and Pisces, till it again reaches Aries. The engraving, which is a perspective view, represents the position when the sun is in the 5th degree of Aquarius, on the 26th of February.

SEBACIC ACID, an acid supposed to have been found in fat of a strong disgusting odour.

SEBATES, salts formed of the sebatic acids, and alkalies, earths, &c.

SECALE RYE, a genus of the digynia order, in the triandria class of plants, and in the natural method ranking under the fourth order, gramina. Rye is commonly sown on poor, dry, limestone or sandy soils, where wheat will not thrive. By continuing to sow it on such a soil for two or three years, it will at length ripen a month earlier than that which has been raised for years on strong cold ground.

SECANT, in Geometry, is a line that cuts another, or divides it into two parts.

SECEDERS, an appellation comprehending those who are dissenters from the established church of Scotland. This secession took place under John Glas in 1727.

SECOND, in Geometry, Chronology, &c. the sixtieth part of a prime or minute, whether of a degree, or of an hour; it is denoted by two small accents, thus ($''$).

SECOND, in Music, an interval of a conjoint degree.

SECONDARY, in general, something that acts as second, or in subordination to, another.

SECONDARY Rocks, are those in which numerous remains of vegetables and animals occur. This division contains sandstone, coal, stratified limestone, chalk, &c. Pebbles and water-worn fragments of rocks belonging to the former divisions, are commonly found in many of the secondary rocks: hence it is inferred, by geologists, that they have been formed at a later period, and hence this class receives its name.

SECRETARY, an officer who, by his master's orders, writes letters, despatches, and other instruments, which he renders authentic by his signet.

SECRETION, in the animal economy, the separation of some fluid mixed with the blood by means of the glands.

SECTION, in Geometry, denotes a side or surface appearing, of a body or figure cut by another; or the place where lines, planes, &c. cut each other.

SECTION of a Building, is the same with its profile; or a delineation of its heights and depths raised on a plane, as if the fabric was cut asunder to discover its inside.

SECTOR, in Geometry, is a part of a circle, comprehended between two radii and the arch; or it is a mixed triangle, formed by two radii and the arch of a circle.

SECUNDINES. After-birth.

SEDAB, in Botany, a name given by the Arabian physicians to the wild or mountain rue, a plant common in Greece, Syria, and other places.

SEDATIVE, in Medicine, nearly synonymous with anodyne; medicines, calculated to assuage pain.

SEDGE GRASSES, a name given to various sorts of grasses of the poor carnation kind. They are hardy in their nature, prevail much in crude heavy land, and are rarely eaten by any cattle.

SEDIMENT, the settlement or dregs of any thing; or that heavy portion of a fluid body which sinks to the bottom of a vessel.

SEDINA, a word used by some writers to express dragon's blood.

SEDITION, among Civilians, is used for a factious commotion of the people, or an assembly of a number of citizens without lawful authority, tending to disturb the peace and order of society.

SEED, in Botany, the essence of the fruit of every vegetable. Linnæus denominates it to be a deciduous part of the plant, containing the rudiments of the new vegetable, and fertilized by the sprinkling of the male dust. Plants are furnished with one seed, as the sea-pink; or two, as in umbelliferous plants; or three, as in the spurge; or many, as in the ranunculus, &c. The shape, structure, and sides of seeds, are various. Linnæus denominates seeds the eggs of plants; and the fecundity of plants is often astonishing: there are 4000 seeds in a single sun-flower; more than 30,000 in a poppy; and in a single tobacco plant 360,000 have been enumerated. The annual produce of a single stalk of spleenwort has been estimated to be a million of seeds. Plants are disseminated in various methods: some are carried along by rivers and torrents many hundred miles from their native soil, and cast upon a very different climate, to which, however, by degrees they render themselves familiar. Some are formed by wings to be borne before the wind to distant places. Birds, squirrels, &c. swallow seeds, and void them whole and fit for vegetation, and thus disseminate them. There are others that disperse themselves by an elastic force, that resides either in the "calyx," as in oats and the fern; in their "pappus," as in the centaurea crupina, or in their "capsule," as in the geranium.

SEGGARS, in the manufacture of porcelain and pottery, are cases formed of coarse clay, capable of sustaining the required heat without fusion; in which different kinds of earthenware are baked.

SEGMENT of a SPHERE, is a part of a sphere terminated by a portion of its surface, and a plane which cuts it off, passing somewhere out of the centre; being more properly called the section of a sphere.

SEIGNORAGE, signifies the right or due belonging to a seigneur or lord; but it is particularly used for a duty belonging to the prince for the coinage of money, called also coinage; which under our ancient kings was five shillings for every pound of gold brought in the mass to be coined, and a shilling for every pound weight of silver. At present the king claims no seignorage at all.

SEINE, the name of a large fishing-net.

SEISIN, in Law, signifies possession.

SEISE, *SEASE*, or *SEAZE*, in the sea language, is to make fast or bind, particularly to fasten two ropes together with rope-yarn.

SEIZING, the operation of fastening any two ropes or dif-

ferent parts of one rope together with a small line or cord. *Seizing*, implies also the cord which fastens them.

SEIZURE, in Commerce, an arrest of some merchandise, moveable or other matter, either in consequence of some law, or of some express order of the sovereign.

SELENIUM. A new substance discovered by M. Berzelius, which has the properties of a metal combined with those of sulphur to so great a degree, that it might be supposed to be a new species of sulphur. In its reguline state, it has a brilliant metallic lustre on the external surface, with a tinge of red; the fracture is vitreous like that of sulphur, but with a very brilliant lustre, of a gray colour.

SELENOGRAPHY, a branch of cosmography, which describes the appearances of the moon, as geography does those of the earth. The invention of telescopes has much improved this branch of human knowledge.

SELF-LOVE, in Ethics, that principle which leads a person to desire and pursue his own happiness. It is contradistinguished from benevolence. Few topics have been more fruitful in generating disputes, respecting its definition, application, and qualities, and few have been left more undecided.

SELL, in Building, is of two kinds, viz. ground-sell, which denotes the lowest piece of timber in a timber building, and that on which the whole superstructure is raised; and the window-sell, called also window-soil, the bottom piece in a window-frame.

SELTZER WATER, the name of a mineral water of Germany, which rises near Seltzer, about four miles from Frankfort on the Mayne. It is much used in England, and many other countries, for its medicinal virtues. It has been found serviceable in scorbutic, cutaneous, and putrid disorders, and is strongly recommended in various other complaints.

SERVAGE, a sort of hank or skein of rope-yarn, used to fasten round any rope as a shroud or stay, by which to hook a tackle, in order to set it up.

SEMEN, a substance prepared by nature for the reproduction and conservation of the species both in animals and plants. The peculiar liquid secreted in the testes of males, and destined for the impregnation of females, is so named. See **SEED**.

SEMICIRCLE, in Geometry, half a circle, or that figure comprehended between the diameter of a circle and half the circumference.

SEMICOLON, in Grammar, one of the points or stops used to distinguish the several members of sentences from each other (;

SEMI-DIURNAL. Of any of those circles which the sun appears to form each daily revolution, that portion which is above the horizon is called the diurnal arch, and that which is below the horizon is called the nocturnal arch, the halves of which are called the semi-diurnal and the semi-nocturnal arches.

SEMI-METALS, a term that expresses those metallic substances not possessing ductility and malleability, these properties being deemed characteristic of real metals.

SEMINARY. See **SCHOOL**.

SEMINARY, in Gardening, is a place allotted for raising plants from seed, and keeping them till they are fit to be removed into the garden or nursery.

SEMITA LUMINOSA, a name given to a lucid track in the heavens, which, a little before the vernal equinox, or after the autumnal, may be seen about six in the evening, extending from the western edge of the horizon up towards the Pleiades. This stream of light bears some resemblance to the tail of a comet.

SENA, or **SENN**, or the *Egyptian Cassia*, in the *Materia Medica*, a purgative leaf much used in draughts, and compositions of that description. It is a native of Egypt; that of the best quality is said to grow in the valley of Basabras, or of Nubia. Senna of an inferior kind grows in the Levant, and about Florence. Its operation is not violent, and it enters into the compound of various medicines.

SENATE, an assembly or council of the principal inhabitants of a state, who have a share in the government. Senates are differently formed according to the political constitutions of various countries.

SENATOR, a member of a senate.

SENDING, a naval term, expressing the act of a ship pitching precipitately into the hollow or interval between two waves,

SENEKA, or **RATTLESNAKE Root**. This plant is a native of Virginia, Pennsylvania, and Maryland, and is now cultivated in some of our gardeus. The root is perennial, the thickness about that of a man's little finger, and its length about four or five inches, being variously contorted and twisted. It has only of late been brought into use among us; but it is thought worthy of great regard. A knowledge of its virtues was first taught the Europeans by the Senegal Indians, who esteemed it a sovereign remedy against the bite of the rattlesnake; in which character it has been found efficacious.

SENNIT, a kind of flat braided cordage used for various purposes, and formed by plaiting five or seven rope-yarns together.

SENSATION, in Physiology, is a general term denoting the effect produced in the mind by the impression of external bodies on our organs of sense, namely, seeing, hearing, feeling, tasting, and smelling.

SENSE, sometimes means the organs of sensation, and at other times it is used for understanding, judgment, and conscience.

SENSIBILITY, the power of receiving an impression, and transmitting it to the brain, so as to occasion an acute sensation or feeling.

SENSITIVE FLUID, a fluid which is supposed to preserve animals from corruption. It is presumed to pass through the nervous tubes, and to convey the impression to the sensorium.

SENSITIVE Plant. See **MIOSA**.

SENSORIUM, the part of man which feels and perceives, the common centre to which sensations are conveyed, and from which volitions emanate.

SENTENCE, in Grammar, a period or set of words comprehending some perfect sense or sentiment of the mind.

SENTENCE, in Law, a judgment passed in court by the judge upon some process either civil or criminal.

SENTINEL, in War, a private soldier placed in some post to watch the motions of an enemy, to prevent surprises, and to stop such as would pass without orders, or shewing who they are.

SEPIA, the cuttle-fish, a genus belonging to the order of vermes mollusca. There are eight brachia interspersed on the interior side with little round serrated cups, by the contraction of which the animal lays fast hold of any thing. Besides these eight arms, it has two tentacula longer than the arms, and frequently pedunculated. The mouth is situated in the centre of the arms, and is horned and hooked. The eyes are below the tentacula, towards the body of the animal. The body is fleshy, and received into a sheath as far as the breast. Their food are tunnies, sprats, lobsters, and other shell-fish. With their arms and trunks they fasten themselves to resist the motion of the waves. Their beak is like that of a parrot. The females are distinguished by two paps. This animal was esteemed a delicacy among the ancients; and is eaten at present by the Italians. The bony scale on the back is that which is sold in the shops, and which, when reduced to fine powder, is reckoned excellent for the teeth, as well for keeping them white as for preserving them. It is also used as pounce. These animals have the power of squirting out a black fluid resembling ink, which is said to be an ingredient used in the composition of Indian ink.

SEPS, in Zoölogy, the name of a peculiar kind of lizard, between that genus and the snakes. It appears as a serpent with feet. Its bite is said to be followed by instant putrefaction and speedy death.

SEPTEMBER, the ninth month of the year, reckoned from January, and the seventh from March, whence its name, viz. Septimus, seventh.

SEPTICS, among Physicians, a name given to all such substances as promote putrefaction.

SEPTUAGINT, the name given to a Greek version of the books of the Old Testament, from its being supposed to be performed by seventy-two Jews, who are usually called the seventy interpreters, because seventy is a round number.

SEPULCHRE, a tomb or place appropriated for the interment of the dead.

SEQUESTRATION, is the separating or setting aside of a thing in controversy, from the possession of both those who

contend for it. A sequestration is also a kind of execution for debt, especially in the case of a beneficed clerk, of the profits of the benefice to be paid over to him that had the judgment, till the debt is satisfied.

SERAGLIO, denotes the palace of a prince or lord. At Constantinople they say the seraglio of the ambassador of England, France, &c. In a more eminent sense, the Turks apply the term to the palace of the grand seignior, where he keeps his court, where his women are kept, and where the youth are trained up for the chief posts in the empire. The whole building is in a triangular form, about three Italian miles in circuit. That part of the seraglio in which the women reside is called the *Harem*.

SERAPH, or **SERAPHIM**, supposed to be an angel of the first or highest rank, and to be more inflamed with divine love than others, and hence the name, which signifies to burn, to inflame.

SERENADE, an evening concert given by a lover under the window of a room in which his mistress resides.

SERGE, in Commerce, a woollen stuff manufactured in a loom, of which there are various kinds, denominated either from their different qualities, or from the places where they are wrought; the most considerable of which is the London serge, which is highly valued abroad.

SERIES, in general, denotes a continued succession of things in the same order, and having the same relation or connexion with each other.

SERIES, *Infinite*, is a series consisting of an infinite number of terms, that is, to the end of which it is impossible to come; so that let the series be carried on to any assignable length, or number of terms, it can be carried yet farther, without end or limitation.

SERICH, the name of a seed used in the food of the Egyptian Copts. It is produced by an herb called *scirum*, and is pounded and put into oil. In this they dip their bread, which is always new, being baked in small cakes, as often as they eat. Raw onions are added to this repast.

SERGEANT, or **SERJEANT**, in War, is an inferior officer in a company of foot, or troop of dragoons, armed with a halberd, and appointed to see discipline observed, to teach the soldiers the exercise of their arms, and to order, straighten, and form ranks, files, &c.

SERJEANT at Law, is the highest degree taken in that profession, as that of a doctor is in the civil law. To these serjeants, as men of great learning and experience, one court is set apart for them to plead in by themselves, which is the court of common pleas, where the common law of England is most strictly observed; yet, though they have this court to themselves, they are not restrained from pleading in any other courts. The judges cannot be elevated to that dignity till they have taken the degree of serjeant at law. They are called brothers by the judges, who hear them next to the king's counsel; but a king's serjeant has precedence of all but the attorney and solicitor general. These are made by the king's mandate, or writ.

SERJEANTY, signifies in law a service that cannot be due from a tenant to any lord, but to the king only; and it is either grand serjeanty, or petit serjeanty.

SERMON, a discourse delivered in public, for the purpose of religious instruction and moral improvement. The present mode of delivering sermons may be traced to the book of Nehemiah, chap. viii. 4.

SERMONIUM, a kind of interlude, which, in ancient times, the inferior clergy, assisted by boys, used to act in the body of the church, on certain festivals. The representative selections were made according to the occasion.

SERPENT, in Music, a wind instrument of the bassoon kind, deriving its name from its serpentine figure.

SERPENT, in Mythology, was a symbol of the sun. He is represented as biting his tail, having his body in a circle, indicating the apparent motion of that luminary round the globe. The serpent biting his tail, is likewise considered as an emblem of eternity. The serpent was, from time immemorial, an object of religious veneration and worship in Egypt; and in subsequent ages, was a symbol of medicine, and of Apollo and Esculapius, the gods which presided over it.

SERPENTES, in Natural History, an order of the Amphibia, containing seven genera; viz. *Achrochordus*, *Amphisbæna*, *An-*
97-8.

guis, *Boa*, *Cœcilia*, *Coluber*, *Crotalus*. Serpents are distinguished as footless amphibia—their eggs are connected in a chain—penis frequently double—they breathe through the mouth—are cast naked upon the earth, without limbs, exposed to every injury, but frequently armed with a poison the most deadly and horrible: this is contained in tubular fangs resembling teeth, placed without the upper jaw, protruded or retracted at pleasure, and surrounded with a glandular vesicle by which this fatal fluid is secreted; but lest this tribe should too much encroach upon the limits of other animals, the benevolent Author of nature has armed about a fifth part only in this dreadful manner, and has ordained that all should cast their skins, in order to inspire a necessary suspicion of the whole. The jaws are dilatable and not articulate, and the œsophagus so lax that they can swallow without any mastication an animal twice or thrice as large as the neck; the colour is variable, and changes according to the season, age, or mode of living, and frequently vanishes, or turns to another, in the dead body; tongue filiform, bifid; skin reticulate. The distinction between the poisonous and innocuous serpents, is only to be known by an accurate examination of their teeth; those which are poisonous being always tubular, and calculated for the injection of the poisonous fluid, from a peculiar reservoir communicating with the fang on each side the head. Serpents in cold and temperate climates conceal themselves during the winter in cavities beneath the surface of the ground, or in any other convenient places of retirement, where they become nearly or wholly in a state of torpidity. Some serpents are viviparous, as the rattlesnake; the viper, &c.; while the innocuous species are oviparous, depositing, as we have observed, their eggs in a kind of chain in any warm and close situation, where they are afterwards hatched. The broad undivided laminae on the bellies of serpents are termed scuta, and the small or divided ones beneath the tail are called subcaudal scales, and from these different kinds of laminae, the Linnæan genera are characterized.

SERPENTINE. This beautiful stone takes its name from its variegated colours being supposed to resemble a serpent's skin. It consists of silica 32, magnesia 37.24, alumina 0.5, lime 10.6, iron 0.06, volatile matter and carbonic acid 14.16. The colours are most generally various shades of light and dark green, which are intermixed in spots and clouds: some varieties are red. When fresh broken, it has some degree of lustre, and a slight unctuous feel. It is harder than lime-stone, but yields to the point of a knife, and will receive a very high polish. When serpentine is found intermixed with patches of crystalline white marble, it constitutes a stone denominated *verde-antique*, which is highly valued for ornamental sculpture. Beautiful varieties of green serpentine occur in the isle of Anglesea, about six miles from the Paris copper mine.

SERVANT, a person who, in consideration of some stipulated remuneration, owes and pays limited obedience to the commands of another in the quality of master. An agreement, when the time is not specified, the law determines to be for one year; but by mutual agreement, a separation may take place at any intermediate stage. Servants are of various kinds and degrees, and several laws regulate their obedience, and the treatment they are entitled to expect.

SERVICE, in Law, is a duty which a tenant, on account of his fee, formerly owed to his lord.

SERVING, is the winding any thing round a rope to prevent it from being rubbed: the materials used for this purpose, which are called service, are generally spun-yarn, small lines, sennit, or ropes, varying in thickness, according to the dimensions of the rope to be served; sometimes leather, old canvass, &c. are used.

SERVITOR, in the university of Oxford, a scholar or student who attends and waits on another for his keep there.

SERVITORS of Bills, such messengers of the marshal of the king's bench as are employed to summon men to that court. They are now commonly called *tipstaves*.

SERUM, a thin transparent liquor, which makes a considerable part in the mass of blood.

SESAMUM, *Oily Grain*, a genus of plants belonging to the class of didynamia, and to the order of angiosperma, and in the natural system ranking under the 20th order, *luridæ*.

SESSION, in Law, denotes a sitting of justices in court upon
11 D

SHIFTED, the state of a ship's ballast or cargo when it is shaken from one side to the other, either by the violence of her rolling, or by her too great inclination to one side under a great pressure of sail; this accident, however, rarely happens, unless the cargo is stowed in bulk, as corn, salt, &c.

SHIFTER, a person appointed to assist the ship's cook in washing, steeping, and shifting the salt provisions.

SHILLER STONE, a mineral nearly allied to serpentine.

SHILLING, an English silver coin, equal to twelve pence, or the twentieth part of a pound.

SHIM, in Agriculture, a tool used in breaking down and reducing the more stiff and heavy sorts of land, as well as cutting up and clearing them from weeds.

SHINGLE, in Agriculture, the thinnings of fir and other timber trees, which are much used in making fences, &c.

SHINGLE, *Rubbish*, found on the sea shore, and used for ballasting ships, protecting embankments, and preventing the encroachments of the sea.

SHINGLES, in Building, small pieces of wood, chiefly oak, used for covering roofs, where other materials are scarce, and something light is required.

SHIP, a general name given to all vessels navigated on the ocean; in the sea language, however, it is more particularly applied to a vessel furnished with three masts, each of which is composed of a lower-mast, a top-mast, and top gallant-mast, with the yards and other machinery thereto belonging. A *Ship cut down*, implies one which has had a deck cut off from her, whereby a three-decker is converted into a two-decker, and a two-decker becomes a frigate. A *Ship raised upon*, is one whose dead works have been heightened by additional timbers.

Hospital SHIP, a vessel fitted up to attend a fleet of men-of-war, and receive their sick or wounded, for which purpose her decks are high, and her ports large. The gun-deck is entirely appropriated for the reception of the sick, and is flush without cabins or bulk-heads, except one of deal or canvass, for separating those in malignant distempers. Two pair of chequered linen sheets are allowed to each bed, and scuttles cut in the sides for inlets of air. The sick are visited by a physician, and constantly attended by a surgeon, a proportional number of mates, assistants, baker, and washerwomen. Her cables ought also to run upon the upper deck to the end, that the beds or cradles may be more commodiously placed between decks, and admit a free passage of the air, to disperse that which is offensive or corrupted.

Merchant SHIP, a vessel employed in commerce to carry commodities of various sorts from one port to another, the largest of which are those used in trading to the East Indies. *Prison Ship*, a vessel fitted up to receive prisoners in a port. *Private Ship of War*. See *PRIVATEER*. *Receiving Ship*, a ship stationed at any place to receive volunteers and impressed men, and train them to their duty in readiness for any ship of war which may want hands. *Slave Ship*, a vessel employed in carrying negro slaves from the coast of Africa to the West Indies, &c. whence she returns to Europe with a cargo of rum, sugar, coffee, cotton, &c. *Slop Ship*, a vessel appointed as a depot of clothes for the seamen. *Store Ship*, a vessel employed to carry artillery and stores for the use of a fleet, fortress, or garrison. *Troop Ship*, is one appointed to carry troops, and is frequently termed a transport.

SHIP Building, may be defined, the manner of constructing ships, or the work itself, as distinguished from naval architecture, which may be considered as the theory or art of delineating ships on a plane.

SHIPWRECKED SEAMEN, *Plan for the Preservation of*, by Captain G. W. Manby.—*Instructions*. After the means of communication have been effected between a stranded vessel and the shore, by a rope attached to a shot projected from a mortar, it is often found a matter of great difficulty to make the persons on board know how they are to act, and many lives have been lost through this cause alone. In order to remedy this evil, and to render it mutually and immediately understood, the following directions are given:

Directions to Persons on Shore.—It is your duty to use every means to secure the safety of the ship and crew.

these have failed, before it is a justifiable resource to run the ship on shore, for the preservation of your own lives. On the determination being made to run for the beach, every exertion should be made to keep your vessel off the shore till high water, and then, if canvass is or can be set, steer the vessel stem on with as much force as possible, making signals of distress to attract the notice of the people on shore, who will collect at the point most favourable for the purpose, and prepare to assist you; endeavour to run for the spot where they are collected. Shipmasters, on these occasions, must enforce their authority more than ever, and seamen must be more than usually obedient, as the safety of all on board will frequently depend on this.

Whether a vessel is thus run on shore, or is stranded, without any choice of time or place, the following directions will equally apply, and must be minutely observed and practised:—Collect, in some safe part of the vessel, ready to apply as occasion may require, all your small lines and ropes, buoys, pieces of cork, or small kegs, (such as seamen keep spirits in,) snatch, tail, and other blocks, with a warp or hawser clear, axes, knives, &c.: all these may be of great use. Attend to the people on shore, and observe if they have a boat, or are getting one to the spot, as their first object would be to launch it to you, and to throw a line on board you, to haul her off with; in that case they will make signal No. 1. The signals, illustrated by representations and their distinct meanings, will be hereafter described. On receiving the line, you will secure the end to such part of the vessel as may best draw the boat into a safe lee. If the people on shore, after you have received the line, make signal No. 2, you will bend the warp or hawser to the line, and they will draw it on shore, fearing to trust the boat to the small line. When the bend is made, and you are ready, make your signal No. 1, (which will be hereafter described, expressing *yes*.) If, when you have got the line, the people on shore find you have not a warp ready, and wish you to haul on board by it a stouter rope to haul the boat off with, they will make signal No. 3, to haul away, for you to receive a stout rope; secure it as before directed, and make your signal No. 1, which is also to denote you are ready, or their direction is complied with.

Remark.—A boat, when it can be applied, is the prompt method of bringing a crew on shore. Upwards of twenty crews have been saved by them.

If, when you have received the line, and observe there is no boat at hand, and the signal on shore (No. 3) is made, you will haul in, and receive by it the end of a stout rope, and a tail-block rove with a small line, both ends of which are kept on shore; make the end of the stout rope and the tail of the block well fast round your mast, higher or lower, as circumstances require, and the tail-block close below the large rope. On your making signal No. 1, denoting to have complied with the direction of having carefully secured the stout rope and tail-block, the people on shore will haul taut the stout rope, and place on it a snatch-block, (with a sling hanging to it large enough to hold a man;) and making the ends of the small line fast to the lower part of the snatch-block, they will work it to the ship, when, on a man getting into the sling, he will, by pulling down the slide or button, secure himself in, and safely

lashing himself by the waist to the upper part of the sling, prevent the possibility of falling out; and on seeing the clap*

* This remark is necessary, from the omission of the clap being here represented, that should cross the mouth of the block.

SHARE, in Agriculture, that part of a plough which enters and breaks the ground.

SHARK, in Ichthyology, a large voracious fish. Of this fish there are several species, as the blue, the basking, and the hammer-headed shark. They chiefly reside in the seas of warm climates, but occasionally visit colder regions. Some have been known to weigh four thousand pounds, and men have been found whole in them when opened.

SHARK See **SQUALUS**.

SHARP, in Music, a character, the power of which is to raise the note before which it is placed half a tone higher than it would be without such a preposition.

SHARP-Bottom, is synonymous with a sharp floor, and is used in contradistinction to a flat floor.

SHASTER, or **SHASTRAM**, a sacred book containing the religion of the Banians; it consists of three tracts: the first of which contains their moral law; the second, the ceremonial; and the third delivers the peculiar observances for each tribe of Indians.

SHAWL, an article of female dress much prized in the East, and now commonly worn in Europe. Their prices vary, from one to 200 guineas, according to the fineness of their texture and materials, and the elegance with which they are finished.

SHEAF, a small bundle of corn in the ear, bound up in the field, for the accommodation of carriage and thrashing.

SHEARING, in Agriculture, the reaping of grain. Shearing also signifies the act of taking off the fleece from the sheep.

SHEARWATER, in Ornithology, a bird well known in the Orkney isles, and in several other places. The young birds are caught in abundance in August, and, salted in barrels, are preserved for winter provisions.

SHEATHING, in Naval Architecture, a sort of covering nailed all over the outside of a ship's bottom, to protect the planks from the pernicious effects of worms. This sheathing, in former years, consisted of thin boards, but sheets of copper having been found far preferable, these have of late been almost universally adopted, especially in long voyages. The corrosion, however, arising from the action of the salt water, being more rapid than was expected, several experiments have been made to counteract its influence. For the improvement of copper sheathing by an alloy, a patent was taken out by Mr. Robert Mushet, of the Royal Mint. His alloy consisted of two ounces of zinc, or four ounces of antimony, or eight ounces of arsenic, or two ounces of grain-tin, being added to one hundred pounds of copper. Another patent was taken out by Mr. Christopher Pope, of Bristol, for an invention which discarded copper altogether, and substituted plates composed of tin and zinc, or of tin, zinc, and lead united. These combinations, however, not fully answering general expectation, the lords of the Admiralty consulted Sir Humphrey Davy on the subject. This scientific gentleman, after a number of experiments, recommended the fixing of small masses or wires of tin, or of some other readily oxidable metal, in contact with the copper, by which he expected that the copper would be rendered so negatively electrical, that the sea water would act but slightly on it. In reducing theory to practice, his anticipations have not, however, been realized according to his wishes; and it is probable that copper sheathing must remain, as heretofore, until some more beneficial method shall appear, that has not yet been discovered.

SHEAVE, a cylindrical wheel of hard wood, fixed by a pin in a block, to form the pulley.

SHECHINAH, in Jewish history, the name of that miraculous light, or visible glory, which was a symbol of the divine presence.

SHED, in rural economy, a slight temporary building, to shelter cattle, or implements of husbandry, from the weather.

SHEEP, in Agriculture, a well-known and valuable animal, of which the breeds and varieties are numerous.

SHEEPSHANK, a sea term, implying a kind of knot made on a rope to shorten it, and is particularly used on runners or ties, to prevent the tackle from coming block and block. By this contrivance, the body to which the tackle is applied may be hoisted much higher, or removed much further in a shorter time. Thus, if any weighty body is to be hoisted into a ship, and it be found that the blocks of the tackle meet before the

object reach the top of the side, it will be necessary to lower it again, or hang it by some other method, till the runner of the tackle is sheepshanked, by which the blocks will again be separated to a competent distance.

SHEER, the longitudinal curve of a ship's decks or sides. *Sheer* is also the position in which a ship is sometimes kept when at single anchor, in order to keep her clear of it; hence, *To break Sheer*, is to deviate from that position, and thereby risk the fouling of the anchor.

SHEERING, or **SHEARING**, in Woollen Manufacture, is the cutting off with large shears the too long nap, in order to make the cloth more smooth and even.

SHEERING, the act of deviating or straying from the line of the course, so as to form a crooked and irregular path through the water, and may be occasioned by the ship's being difficult to steer, but it more frequently arises from the negligence or incapacity of the helmsman. *To Sheer up alongside*, to approach a ship in a parallel direction. *To Sheer off*, to remove to a greater distance.

SHEERS, a nautical term, the name of an engine used to hoist in or get out the lower masts of a ship, and are either placed on the side of a quay or wharf, or are fixed on board of an old ship cut down; or, lastly, they are composed of two masts or large spars lashed together, and erected in the vessel wherein the mast is to be planted or displaced, the lower ends of the props resting on the opposite sides of the deck, and the upper parts being fastened together across, from which a tackle depends; this sort of sheers is secured by stays extending to the stem and stern of the vessel.

SHEET, a rope fastened to one or both the lower corners of a sail, to extend and retain it in a particular situation. When a ship sails with a side wind, the lower corners of the main and fore sails are fastened by a tack and a sheet, the former being to windward, and the latter to leeward; the tack is, however, only disused with a stern wind, whereas the sail is never spread without the assistance of one or both of the sheets; the stay-sails and studding-sails have only one tack and one sheet each; the staysail tacks are fastened forward and the sheets drawn aft, but the studding-sail tacks draw the outer corner of the sail to the extremity of the boom, while the sheet is employed to extend the inner corner: hence, *To Sheet home*, is to haul home a sheet, or to extend the sail till the clue is close to the sheet-block.

SHEKEL, in Jewish Antiquity, an ancient coin, worth 2s. 3½d. sterling.

SHELF, among Miners, the same with what they otherwise call fast ground, or fast country; being that part of the internal structure of the earth, which they find lying even and in an orderly manner.

SHELL, in Artillery. See the article *Bomb*, &c. *Shell of a Block*, the outer frame, or case, wherein the sheave or wheel is contained, and traverses about its axis.

SHELLS. Marine shells may be divided, as Mr. Hatchet observes, into two kinds: those that have a porcelainous aspect with an enamelled surface, and when broken are often in a slight degree of a fibrous texture; and those that have generally, if not always, a strong epidermis, under which is the shell, principally or entirely composed of the substance called nacre, or mother-of-pearl. The porcelainous shells appear to consist of carbonate of lime, cemented by a very small portion of animal gluten. This animal gluten is more abundant in some, however, as in the patalla. The mother-of-pearl shells are composed of the same substance. They differ, however, in their structure, which is lamellar, the gluten, forming their membranes, regularly alternating with strata of carbonate of lime. In these two the gluten is much more abundant.

SHEPHERD, one who has the care and management of sheep.

SHERIFF. As keeper of the king's peace, the sheriff is the first man in the county, and superior in rank to any nobleman therein, during his office. He may apprehend and commit to prison all persons who break the peace, or attempt to break it, and may bind any one in a recognizance to keep the king's peace.

SHIELD, an ancient weapon of defence, in the form of a light buckler, borne on the arm, to turn off lances, darts, &c.

pieces of lead, and then to throw it on shore: but this he soon found could not be serviceable when the vessel lay contiguous to the coast. His second scheme was that of hoisting a kite, and permitting it to hang over the land, and then causing it to fall where the people on the beach or rocks might seize it, and draw a line on shore. In this he at first placed much confidence, but after some time he saw reason to abandon it, as being too uncertain to justify dependence. His third method was that of a rocket, which he says has answered his most sanguine expectations. A line being thus thrown on shore by means of the rocket, and drawn by the people on the land, can soon bring from the wreck a rope, which, being made fast and drawn as speedily as possible, will enable those on board to put his life-preserver into immediate use.

"A model of the Preserver," he observes, "and a written description of it, I showed to a gentleman in this neighbourhood, who consulting with a friend of his who had formerly belonged to the Admiralty, was led with his friend to conclude that the invention was entitled to consideration. The former gentleman then caused it to be transmitted to Government, after which I heard no more about it. Probably the bustle created by the war in the naval department, and my not having made a single experiment with any part of the apparatus, to ascertain its practicability, as a recommendation for its adoption, might have been two reasons why it was not attended to. Several months had now elapsed without my hearing any thing about it, or making any experiments. But my feelings were as much alive as ever to the object I had in view; and although I did not succeed in my first efforts, I proceeded under the unaltered conviction that the principle was good, and that if the apparatus should become a portable part of the ship's equipment, in case of a wreck many lives might be preserved. To ascertain the most effectual means for accomplishing this desirable object, I tried many experiments; but though in some cases the use of a musket might answer every purpose, I finally gave the preference to the rocket. With these, after making numerous attempts, I have so far succeeded, as to believe, that there is not another man in the united kingdom who can project a line to an equal distance, and with equal precision and promptitude, with any description of apparatus equal in portability, which is not on the same principle. The line which I project is adequate to draw a rope on shore sufficiently large to be used as a hauling-rope to draw persons through the water, or above the water on a hawser. If through the water, then a float is to be affixed on the rope, which may be done in a minute, and wrapped round the body of the person to be floated to land; when, committing himself to the water, he will be instantly drawn to the shore. On being thus saved, the float must again be hauled to the wreck for the next person; and thus continue to pass and repass until all are secured. But if the stranded vessel should not go immediately to pieces, a hawser may be carried from the wreck and made fast on shore. This being drawn tight, all on board may be landed comfortably and quickly, by means of a *chaise rolante*, suspended on wheels that are curiously contrived to run upon the hawser. They are so constructed that they may be worked with the utmost rapidity, without producing any observable friction. The *chaise rolante* is a safe, easy, and comfortable conveyance; it affords the accommodation of an arm-chair, and is perfectly secure for the infirm, the sick, or wounded, and also for women and children. It is so portable, that a child of three years of age may carry it under his arm. With these parts of the apparatus, I made my first experiments at Porthleven in 1816. This was the first time that the float was ever in the water, and that the *chaise rolante* was ever suspended to a rope. A great number of spectators was present; among whom were several respectable gentlemen; to whom general satisfaction was given." Of this experiment the following account was afterwards published by a Mr. Russell, who was a spectator of what he here relates. "On Friday last, Mr. Trengrouse publicly exhibited the use of his apparatus at Porthleven. From the western shore he threw several lines across the harbour, which went over the pier to some distance on the outer side. The length of line projected was about 200 yards. He has so perfected this part of his plan, as certainly to render it superior to every other method. A float made of cork was applied to the body of a man with his clothes on,

who volunteered his services though the wind blew hard. He was soon hauled across the harbour in a buoyant state. The advantages of this float must be obvious to any one, who has ever witnessed the manner in which shipwrecked mariners are dragged through the foaming surf, from their perishing vessel to the shore. They are almost killed, that their lives may be saved. The same man who had thus been drawn across the harbour in the float, soon made a signal to return by the same route. He accordingly took his seat in the *chaise rolante*, suspended to a large rope, which had been drawn across the harbour. In this he was conveyed over, and back again, in little more than two minutes."

After this first attempt, Mr. Trengrouse made several experiments before many scientific gentlemen, high in rank, both in the naval and military department, to whose his invention gave the fullest satisfaction. These have attested their approbation by their signatures, and the importance of his life-preserver has been so far appreciated as to procure for the inventor a diamond ring from the emperor of Russia.

SHOAL, in Mining, stones containing ore mixed with rubbish in a loose soil, and sometimes near the surface. When deep, the miners consider it as indicating that some vein is at no great distance.

SHOAL, a term synonymous with shallow.

SHOAR, a prop or stanchion fixed for support against a wall, or under a ship's sides or bottom, to support her when laid aground, or on the stocks, &c.

SHOE, a covering for the foot, usually made of leather.

Shoe of the Anchor, a small block of wood, convex on the back, and having a hole sufficiently large to contain the point of the anchor-fluke on the fore side; it is used to prevent the anchor from tearing the planks on the ship's bow, when ascending or descending; for which purpose the shoe slides up and down along the bow, between the fluke of the anchor and the planks, as being pressed close to the latter by the weight of the former. *To Shoe an Anchor*, is to cover the flukes with a broad triangular piece of thick plank, whose area is greater than that of the flukes. Its use is to give the anchor a stronger and surer hold in very soft or oozy ground.

Shoeing of Horses, a term applied to the operation of fastening pieces of iron on the bottom parts of the hoofs, or that of nailing the shoes to their feet. This is an employment which requires much care, that the hoofs may not be injured, and that the animal may not be made lame.

SHOOT, in Agriculture and Gardening, the young branch of any sort of plant, which is produced in one season.

SHOPLIFTER, one who, under the pretence of purchasing goods in a shop, takes an opportunity to steal them. If the amount stolen be above five shillings, the thief is guilty of felony, without benefit of clergy, by 10 and 11 W. III. c. 22.

SHORE, in Agriculture, a sort of artificial drain, formed in low flat lands, for relieving them from the waters collected on their surface.

SHORE, the general name for the sea-coast of any country. *Bold Shore*, a coast which is steep and abrupt, so as to admit the near approach of shipping, without exposing them to the danger of being stranded; and is used in contradistinction to a shelving shore.

SHOT, a missile weapon, discharged by the force of ignited powder from a fire-arm in battle; of these there are various kinds, as, *Round Shot*, or *Bullets*, a ball or globe of iron, whose weight is in proportion to the bore of the cannon. *Double-headed*, or *Bar Shot*, are formed of a bar with a round head at each end, which fits the muzzle of the cannon. The middle is sometimes filled with a composition, and the whole covered with linen dipped in brimstone; so that the cannon, in firing, inflames the combustibles or composition of this ball, which sets fire to the sails of the enemy. One of the heads of this ball has a hole to receive a fuse, which communicating with the charge of the cannon, sets fire to the bullet. *Chain Shot*, consist of two balls chained together, being principally designed to annoy the enemy by cutting her sails, rigging, &c. *Grape Shot*, is a combination of balls strongly corded in canvass upon an iron bottom, so as to form a sort of cylinder, whose diameter is equal to that of the ball which is adapted to the cannon. *Case Shot*, or *Cannister Shot*, are composed of a

great number of small bullets, put into a cylindrical tin box. They are principally used when very near, to clear the decks of the enemy. Besides these, there are others of a more pernicious kind, used by privateers, pirates, &c. such are langrage shot, star shot, fire-arrows, &c. Star shot consists of four pieces of iron, whose bases, when separate, form the quadrant of a circle; so that the whole being joined, forms a cylinder equal to the shot of the cannon. Each of these pieces is furnished with an iron bar, the extremity of which is attached to a sort of link, as keys are strung upon a ring. Being discharged from the gun, the four branches or arms extend every way from the link in the centre. These also are chiefly intended to destroy the sails or rigging; but their flight and execution are very precarious at any tolerable distance.

SHOVEL, in Agriculture, a well-known implement, with a long handle and wide blade, used instead of a spade, and by some labourers preferred to it. Shovels are differently formed, according to the purpose for which they are applied.

SHOWER, a cloud resolved into rain, and discharged during a limited period on a certain tract of ground.

SHRIMP, in Natural History, is the cancer crangan of Linnaeus. This shell-fish inhabits the sandy shores of Great Britain in vast quantities, and is reckoned a great delicacy. In form, the shrimp nearly resembles the lobster.

SHRINE, in Ecclesiastical History, a case or box to hold the relics of some saint.

SHROUDS, a range of large ropes extended from the mast-heads to the right and left sides of a ship, to support the masts, and enable them to carry sail, &c. The shrouds are always divided into pairs or couples, that is to say, one piece of rope is doubled, and the parts fastened together at a small distance from the middle, so as to leave a sort of noose or collar to fix upon the mast-head; the ends which reach to the deck have each a dead-eye turned in or fastened to them, by which they are extended to the channel. The shrouds, as well as the sails, &c. are denominated from the masts to which they belong; thus there are the main, fore, and mizzen shrouds; the main-top-mast, fore-top-mast, and mizzen-top-mast shrouds; and the main-top-gallant, fore-top-gallant, and mizzen-top-gallant shrouds. *The Top-mast Shrouds* are extended from the top-mast head to the edges of the tops by the foot-hook plates. See the article **PLATE**. The upper ends of the futtock-shrouds are furnished with iron hooks, which enter holes in the lower ends of the foot-hook plates, so that when the top-mast shrouds are set up or extended, the futtock shrouds require an equal tension. *The Top-gallant Shrouds* are extended to the cross-trees, where passing through holes in their ends, they continue over the futtock-staves of the top-mast rigging, and descending almost to the top, are set up by laniards passing through thimbles instead of dead-eyes. *Futtock or Foot-hook Shrouds* are pieces of rope communicating with the futtock-plates above and the earharplings below, and forming ladders whereby the sailors climb up to the top-brid. *Bowsprit Shrouds* are shrouds put over the head of the bowsprit, and extended on each side to the ship's bows, to support the former. *Bumkin Shrouds* are strong ropes, fixed as stays or supports to the bumkin ends, to prevent their rising by the efforts of the fore-tacks upon them. *Bentick Shrouds* are strong ropes fixed on the futtock-staves of the lower rigging, and extending to the opposite channels, where they are set up by means of dead-eyes and laniards, in the same manner as the other shrouds; their use is to relieve or support the masts when the ship rolls.

SHROUN, a shelter or cover, is used to denote the dress of the dead. If any person, in taking up the dead body, steals the shroud, the property of which remains in the executor, or the person who was at the charge of the funeral, it is felony.

SHROVETIDE, the time immediately before Lent, and thus called by our ancestors, because employed in *shrieving*, that is, in confessing their sins to the priest, in order to a more devout keeping of the ensuing Lent fast. *Shrove Tuesday*, is the day next before the beginning of Lent.

SHROWDING OF TREES, is the cutting or lopping off the top branches of such trees as are not fit for timber. Ash trees of this kind are sometimes called pollards.

SHRUBS, in Botany and Vegetable Physiology, are commonly understood to be plants with a perennial woody stem,

of a more humble and slender form of growth than those denominated trees.

SHRUBBERY, a portion of ground planted with shrubs, trees, and flower plants, for the purpose of ornament.

SHUCK, or **SHOCK**, in Agriculture, ten or twelve sheaves of corn placed together in an erect position, in a harvest field, with the corn upwards. It is sometimes called *stock*.

SHUME, or **ASSHUME**, an exceedingly hot wind of Africa, which, in the intermediate journeys between several parts of the great desert, or Sahara, occasions great inconvenience and distress to travellers. It sometimes wholly exhales the water carried in skins by the camels for the use of the travelling party; and instances have occurred, when five hundred dollars have been offered for a draught of water. From ten to twenty is a common price when a partial exhalation has taken place. In 1805, a caravan proceeding from Timbuctoo to Taflet, was disappointed at finding no water at one of the usual watering places; and such was the calamity, that it is said all the persons belonging to it, 2000 in number, and 1800 camels, perished by thirst.

SHUTTLE, in the Manufactures, an instrument much used by weavers, in the middle or near the end of which is an eye or cavity wherein is enclosed the spool with the woof.

SIWAN PAN, the name of a Chinese instrument, which they use to assist them in their computations. It is composed of wires with beads upon them, which they move backwards or forwards, as occasion requires. See **ABACUS**.

SIALAGOGUES, in Medicine, the name of all such simples or compounds as increase the flow of saliva.

SIBERS, an infectious disease of a chronic nature, somewhat resembling the syphilis, prevalent in the western parts of Scotland. It is said to be so denominated, from the appearance of a fungous exuberance from some of the cutaneous sores, not unlike a raspberry; the word *sibben*, or *sirren*, being the Highland appellation for a wild raspberry. This disease is not of ancient date in Scotland.

SIBSIT, in Zoology, an animal of the empire of Morocco, abounding in the mountains of Suse, of an intermediate species between the cat and the squirrel.

SIBYLS, ancient virgin prophetesses, whose fame has been spread throughout the world. Their books were held sacred in Rome, but were destroyed when the capitol was burnt, eighty-five years before Christ. Other copies were afterwards collected, but they are acknowledged to be imperfect, if not altogether fabulous.

SICARII, in ancient history, assassins of Judea, who went about the country committing depredations, with short swords concealed under their garments. Josephus has described them in the most odious colours.

SICE-ACE, a game with dice, and tables, whereat five may play, each having six men; and the last out, losing. At this game they load one another with aces; sixes bear away; and doublets drinks, and throws again.

SICERA, the Hellenist Jews give this name to any intoxicating liquor. Some have thought that it meant nothing but palm wine.

SICKLE, in Agriculture, a toothed-hook used in reaping corn. There are great varieties in their construction.

SICUB, a species of hawk, about the common size, well known in the Philippine islands. Its plumage is elegantly variegated with yellow, white, and black.

SIDDOW, a peculiar kind of peas that boil freely. It is well known in some districts in Gloucestershire.

SIDEREAL DAY, is the time in which any star appears to revolve from the meridian to the meridian again; which is 23 hours 56' 4" of mean solar time; there being 366 sidereal days in a year, or in the time of 365 diurnal revolutions of the earth.

SIDERATION, the blasting or blighting of trees, plants, &c. by eastern winds, excessive heat, continued drought, and similar causes.

SIDERITES a name which some authors give to the load-stone.

SIDERITIS, a plant, supposed to be efficacious for stanching of blood and healing of wounds, if newly made.

SIDEROMANTIA, an ancient kind of divination by laying straws upon red-hot iron. By observing their figures, bend-

ings, sparkling, and burning, the imaginary prognostics were obtained.

SIDES-MEN, or **SYNOD'S MEN**, persons who in large parishes are appointed to assist the churchwardens in their inquiry and presentments of such offenders to the ordinary, as are punishable in the spiritual court.

SIEGE, in the art of war, the encampment of an army before a fortified place, with a design to take it.

SIENITE, a stone composed of felspar and hornblende, and sometimes quartz and black mica. The transitions by which granite passes into sienite, and the latter into porphyry, trap, and basalt, are gradual, and in some rocks almost imperceptible. These changes are principally effected by an intermixture of the mineral already described under the name of Hornblende.

SIERRA, is a word used for hill in various parts of the world, particularly on the west coast of Africa, on the north coast of South America, and on the coasts of Chili and Peru on the South Pacific ocean.

SIERRILLO, the term for a little hill, being a diminutive from Sierra; in which sense it is used on the south-west coast of South America also.

SIEVE, or **SEAVE**, an instrument serving to separate the fine from the coarse parts of powders, liquors, &c. and to cleanse pulse and corn from dust, light grain, &c.

SIGAH GUSH, in Zoology, the name of a Persian animal of the cat kind, and no way differing from the lynx, only that it has no spots.

SIGHING, an effort of nature, by which the lungs are put into quicker motion, and become more dilated, so that the blood passes more freely, and in greater quantity, to the left auricle, and thence to the ventricle.

SIGHT. See **EYE**.

SIGHTS OF A QUADRANT, &c. thin pieces of brass raised perpendicularly on its side, or on the index of a theodolite, circumferentor, &c.

SIGN, in Astronomy, a constellation containing a twelfth part of the zodiac, or thirty degrees.

SIGNALS, certain notices used to communicate intelligence to distant objects. At sea they are made by firing artillery, displaying flags and pendants, lanterns or fire-works, as rockets and false-fires, and these are combined by multiplication and repetition; by which combination of signals, previously known, the admiral conveys orders to his fleet, every squadron, every division, and ship, of which, has its particular signal. Every ship to which a signal is made, immediately answers it by hoisting some particular flag, to shew that she has received and understands the order thereby conveyed. All signals may be reduced into three different kinds, viz. those which are made by the sound of particular instruments, as the trumpet, horn, or fife; to which may be added, striking the bell, or beating the drum. Those which are made by displaying pendants, ensigns, and flags of different colours; or by lowering or altering the position of sails; and, lastly, those which are executed by rockets of different kinds, by firing cannon or small arms, by artificial fire-works, and by lanterns. All signals, to be effectual, must be simple, and composed in such a manner as to express the same signification at whatever mast-head or yard-arm they may be displayed from. They should be issued without precipitation, exposed in a conspicuous place, so as to be seen at a distance, and sufficient time should be allowed to observe and obey them. Signals are very numerous and important, being all appointed and determined by order of the lord high admiral, or lords of the admiralty, and communicated in the instructions sent to the commander of every ship of the fleet or squadron, before their putting out to sea. Few subjects have more seriously engaged the attention of nautical men than that of signals; the labour, however, and study that has hitherto been expended on them, appear, even in the opinion of the inventors themselves, not to have been completely productive of that precision and correctness in conveying orders which is certainly the grand desideratum. The object is undoubtedly of the first consequence to a maritime power; the greatest inconveniences have at different times arisen, as well in action as on other occasions, from the imperfect state of the code, and consequently every attempt to improve its effects, and diminish its imperfections, is truly laudable and worthy of

consideration. The firing of great guns is common in the day night, or in a fog, to make or confirm signals; yet it must be confessed, that too great a repetition is apt to introduce mistakes and confusion, as well as to discover the track of the squadron. The report and flight of the rockets is liable to the same objection, when at a short distance from the enemy.

Signals by Day.—When the commander-in-chief would have them prepare for sailing, he first loosens his fore-top-sail, and then the whole fleet are to do the same. When he would have them unmoor, he loosens his main-top-sail and fires a gun, which in the royal navy is to be answered by every flag-ship. When he would have them weigh, he loosens his fore-top-sail and fires a gun, and sometimes hauls home his sheets; the gun is to be answered by every flag-ship, and every ship to get to sail as soon as she can. If with the leeward side, the sternmost ship is to weigh first. When he would have the weathermost and headmost ships to tack first, he hoists the union-flag at the fore-top-mast head, and fires a gun, which each flag-ship answers; but if he would have the sternmost and leewardmost ships tack first, he hoists the union-flag at the mizzen-top-mast head, and fires a gun; and when he would have all the whole fleet tack, he hoists an union, both on the fore and mizzen-top-mast heads, and fires a gun. When, in bad weather, he would have them wear and bring to the other tack, he hoists a pendant on the ensign-staff and fires a gun, and then the leewardmost and sternmost ships are to wear first and bring on the other tack, and lie by, or go on with an easy sail till he comes ahead: every flag is to answer with the same signal. If they are lying or sailing by a wind, and the admiral would have them bear up and sail before the wind, he hoists his ensign and fires a gun, which the flags are to answer; and then the leewardmost ships are to bear up first, and to give room for the weathermost to wear, and sail before the wind with an easy sail, till the admiral comes ahead. But if it should happen, when the admiral has occasion to wear, and sail upon the wind, that both jack and ensign be abroad, he will haul down the jack before he fires the gun, to wear and keep it down till the fleet is before the wind. When they are sailing before the wind, and he would have them bring to, with the starboard tacks aboard, he hoists a red flag at the flag-staff, on the mizzen-top-mast head, and fires a gun. But if they are to bring to with the larboard tack, he hoists a blue flag at the same place, and fires a gun, and every ship is to answer the gun. When any ship discovers land, he is to hoist his jack and ensign, and keep it abroad till the admiral or commander-in-chief answers him by hoisting his; on sight of which he is to haul down his ensign. If any discover danger, he is to tack and bear up from it, and to hang his jack abroad from the main-top mast cross-trees, and fire two guns; but if he should strike or stick fast, then, besides the same signal with his jack, he is to keep firing till he sees all the fleet observe him, and avoid the danger. When any sees a ship or ships more than the fleet, he is to put abroad his ensign, and there keep it, till the admiral's is out, and then to lower it, as often as he sees ships, and stand in with them, that so the admiral may know which way they are, and how many; but if he be at such a distance that the ensign cannot well be discovered, he is then to lay his head towards the ship or ships so descried, and to brail up his lower sails, and continue hoisting and lowering his top-sails, and making a waft with his top-gallant-sails, till he is perceived by the admiral. When the admiral would have the vice-admiral, or him that commands in the second post of the fleet, to send out ships to chase, he hoists a flag, striped white and red, on the flag-staff, at the fore-top-mast head, and fires a gun. But if he would have the rear admiral do so, he then hoists the same signal on the flag-staff at the mizzen-top-mast head, and fires a gun. When the admiral would have any ship to chase to windward, he makes a signal for speaking with the captain, and he hoists a red flag in the mizzen-shrouds, and fires a gun; but if to chase to leeward, a blue flag; and the same signal is made by the flag in whose division the ship is. When he would have them give over the chase, he hoists a white flag on the flag-staff at the fore-top-mast head, and fires a gun; which signal is to be made also by that flag-ship which is nearest the ship that gives the chase, till the chasing ship sees the signal. In case of springing a leak, or any other disaster that disables their

ship from keeping company, they are to haul up their courses, and fire two guns. When any ship would speak with the admiral, he must spread an English ensign from the head of his main and fore-top-mast downwards on the shrouds, lowering his main or fore-top-sail, and firing guns till the admiral observes him; and if any ship perceive this, and judge the admiral does not, that ship must make the same signal to acquaint the admiral therewith, who will answer by firing one gun. When the admiral would have the fleet to prepare to anchor, he hoists an ensign, striped red, blue, and white, on the ensign-staff, and fires a gun, and every flag-ship makes the same signal. If he would have the fleet moor, he hoists his mizzen-top-sail with the clue-lines hauled up, and fires a gun. If he would have the fleet cut or slip, he loosens both his top-sails, and fires two guns; and then the leeward ships are to cut or slip first, to give room to the weathermost to come to sail. So, if he would have any particular ship to cut or slip, and to chase to windward, he makes the signal for speaking with that ship, hoists a red flag in the mizzen-shrouds, and fires a gun; but if the ship is to chase to leeward, he hoists a blue flag as before. If he would have the fleet exercise their small arms, he hoists a red flag on the ensign-staff, and fires a gun; but if the great guns, then he puts up a pendant over the red flag.

Signals by Night.—Night signals should be used as little as possible, since they are frequently misunderstood. Of necessity, they must be composed of either sound or light, or the two blended together. Those to be observed at an anchor, weighing anchor, and sailing, are as follow: when the admiral would have the fleet to unmoor and ride short, he hangs out three lights, one over another, in the main-top-mast shrouds, over the constant light in the main-top, and fires two guns, which are to be answered by flag-ships; and each private ship hangs out a light in the mizzen-shrouds. *N. B.* All guns, fired for signals in the night, must be fired on the same side, that they may make no alteration in the sound.—When he would have them weigh, he hangs a light in the main-top-mast shrouds, and fires a gun, which is to be answered by all the flags, and every private ship must hang out a light in her mizzen shroud. When he would have them tack, he hoists two flags on the ensign-staff, one over another, above the constant light in his poop, and fires a gun, which is to be answered by all the flags; and every private ship is to hang out a light extraordinary, which is not to be taken in till the admiral takes in his. After the signal is made, the leewardmost and sternmost ships must tack as fast as they can, and the sternmost flag-ship, after she is about on the other tack, is to lead the fleet, and her they are to follow, to avoid running foul of one another in the dark. When he is upon a wind, and would have the fleet veer and bring to on the other tack, he hoists up one light on the mizzen-tack, and fires three guns, which is to be answered by the flag-ships, and then every private ship must answer with one light at the mizzen-peck. The sternmost and leewardmost ships are to bear up as soon as the signal is made. When he would have them in blowing weather to lie by, short, or a-hull, or with the head-sails braced to the mast, he will form lights of equal height, and fire five guns, which are to be answered by the flag-ships, and then every private ship must shew four lights; and after this, if he would have them make sail, he then fires ten guns, which are to be answered by all the flags, and then the headmost and weathermost ships are to make sail first. When the fleet is sailing large, or before the wind, and the admiral would bring them to, and lie by with their starboard-tacks aboard, he puts out four lights in the fore-shrouds, and fires six guns; but if with the larboard-tacks aboard, he fires eight guns, which are to be answered by the flag-ships, and every private ship must shew four lights. The windward ships must bring to first. Whenever the admiral alters his course, he fires one gun, without altering his lights, which is to be answered by all the flag-ships. If any ship have occasion to lie short, or by, after the fleet has made sail, he is to fire one gun, and shew three lights in the mizzen-shrouds. When any one first discovers land, or danger, he is to shew as many signs as he can, to fire one gun, and to tack or bear away from it; and if any one happens to spring a leak, or be disabled from keeping company with the fleet, he hangs out two lights of equal height, and fires

guns till he is relieved by some ship of the fleet. If any one discovers a fleet, he is to fire guns, make false fires, put one light out on the main-top, three on the poop, to steer after them, and to continue firing of guns, unless the admiral calls him off by steering another course, and firing two or three guns; for then he must follow the admiral. When the admiral anchors, he fires two guns, a small space of time one from the other, which are to be answered by the flag-ships, and every private ship must shew two lights. When the admiral would have the fleet to moor, he puts a light on each top-mast head, and fires a gun, which is to be answered by the flag-ships, and every private ship is to shew one light. If he would have them lower their yards and top-masts, he hoists one light upon his ensign-staff, and fires one gun, which is to be answered by the flag-ships, and every private ship is to shew one light. And when he would have them hoist their yards and top-masts, he puts out two lights, one under the other, in the mizzen-top-mast shrouds, and fires one gun, which is to be answered by the flag-ships, and each private ship must shew one light in the mizzen-shrouds. If any strange ship be discovered coming into the fleet, the next ship is to endeavour to speak with her, and bring her to an anchor, and not suffer her to pass through the fleet. And if any one discovers a fleet, and it blows so hard that he cannot come to give the admiral timely notice, he is to hang out a great number of lights, and to continue firing gun after gun, till the admiral answers him with one. When the admiral would have the fleet to cut or slip, he hangs out four lights, one at each main-yard-arm and at each fore-yard-arm, and fires two guns, which are to be answered by the flag-ships, and every private ship is to shew one light.

Signals in a Fog.—Fog signals can only be composed of sound at different intervals. When, therefore, the admiral would have them weigh, he fires ten guns, which every flag-ship is to answer. To make them tack, he fires four guns, which are to be answered by the flag-ships, and then the leewardmost and sternmost ships must tack first, and after they are about, to go with the same sail they tacked with, and not to lie by, expecting the admiral to come a-head, and this is to avoid the danger of running foul of one another in thick weather. When the admiral brings to, and lies with his head-sails to the mast, if with the starboard tack aboard, he fires six guns; but if with the larboard tack, he fires eight guns, which the flag-ships are to answer. And, after this, if he make sail, he fires ten guns, which the flag-ships must answer, and then the headmost and weathermost ships are to make sail first. If it grow thick and foggy weather, the admiral will continue sailing with the same sail set that he had before it grew foggy, and will fire a gun every hour, which the flag-ships must answer by firing of muskets, beating of drums, and ringing of bells. But if he be forced to make either more or less sail than he had when the fog began, he will fire a gun every half hour, that the fleet may discern whether they come up with the admiral, or fall astern of him; and the flags and private ships are to answer as before. If any one discovers danger which he can avoid, by tacking and standing from it, he is to make the signal for tacking in a fog; but if he should chance to strike and stick fast, he is to fire gun after gun, till he thinks the rest have avoided the danger. When the admiral would have the fleet to anchor, he fires two guns, which the flags are to answer; and after he has been half an hour at anchor, he will fire two guns more, to be answered by the flags, as before, that all the fleet may know it.

Signals for calling Officers on board the Admiral.—When the admiral puts abroad a union-flag in the mizzen-shrouds, and fires a gun, all the captains are to come aboard him; and if with the same signal there be also a waft made with the ensign, then the lieutenant of each ship is to come on board. If an ensign be put abroad in the same place, all the masters of the ships of war are to come on board the admiral. If a standard on the flag-staff be hoisted at the mizzen-top-mast head, and a gun fired, then all the flag-officers are to come on board the admiral. If the English flags only, then a standard in the mizzen-shrouds, and fire a gun; if the flags and land general officers, then the admiral puts abroad a standard at the mizzen-top-mast head, and a pendant at the mizzen-peck, and fires a gun. If a red flag be hoisted in the mizzen-shrouds, and a gun fired, then the captains of his own squadron are to come aboard

Custom-house officers and the tenants, with their servants, may hasten to give all possible assistance, as well as to prevent the wreck from being plundered. 2. In every great storm two men on horseback are sent from the castle to patrol along the coast from sun-set to sun-rise, that in case of any accident, one may remain by the ship, and the other return to alarm the castle. Whoever brings the first notice of any ship or vessel being in distress, is entitled to a premium in proportion to the distance from the castle; and if between twelve o'clock at night and three o'clock in the morning, the premium to be doubled. 3. A large flag is hoisted when there is any ship or vessel seen in distress upon the Fern Islands, or Staples, that the sufferers may have the satisfaction of knowing their distress is perceived from the shore, and that relief will be sent them as soon as possible. In case of bad weather, the flag will be kept up, a gun fired morning and evening, and a rocket thrown up every night from the north turret, till such time as relief can be sent. There are also signals to the Holy Island fishermen, who, from the advantage of their situation, can put off for the islands at times when no boat from the main land can get over the breakers. Premiums are given to the first boats that put off for the islands, to give their assistance to ships or vessels in distress, and provisions are sent in the boat. 4. A bell on the south turret will be rung in every thick fog, as a signal to the fishing-boats; and a large swivel fixed on the east turret, will be fired every fifteen minutes, as a signal to the ships without the islands. 5. A large weather-cock is fixed on the top of the flag-staff, for the use of the pilots. 6. A large speaking-trumpet is provided, to be used when ships are in distress near the shore, or are run aground. 7. An observatory, or watch-tower, is built on the east turret of the castle, where a person is to attend every morning at daybreak during the winter season, to look out if any ships are in distress. 8. Masters and commanders of ships and vessels in distress, are desired to make such signals as are usually made by people in their melancholy situation. Besides these signals for affording relief, stores, provisions, necessary articles for raising ships that are stranded, in order to their being prepared. Coffins for the dead, &c. are also provided.

Day SIGNALS, are usually made by flags and pendants, sometimes accompanied with one or more guns.

Night SIGNALS, are either lanterns disposed in certain figures, as lines, squares, and triangles, or are made with false fires, &c.

Fog SIGNALS, consist of operations which emit sound, as firing cannon or muskets, beating drums, ringing bells, &c.

SIGNATURE, a subscription, or putting one's name at the bottom of an act or deed, in personal hand writing, or mark.

SIGNATURE, in Printing, is a letter put at the bottom of the first page, at least, in each sheet, as a direction to the binder in folding, gathering, and collating them.

SIGNET. See *Sign MANUAL*.

SIGNIFICATION, the sense or meaning of a word, phrase, emblem, or device. The signification of the ancient hieroglyphics is but little known.

SIGNINUM, among the Romans, was a kind of pavement much esteemed. It was made of powdered shells mixed with lime.

SIGN-MANUAL, in Law, is used to signify a bill or writing signed by the king's own hand.

SIKE, a term provincially applied to a little rill, a water furrow, and a gutter.

SIL, in Canals, the bottom timbers of sluices, lockgates, &c.

SIL, in Natural History, peculiar kinds of ochres, well known as valuable paints.

SILICA, **SILEX**, **SILICIUM**, or *Silicious Earth*, is one of the most abundant substances in nature, and is the chief component part of sand, sandstone, flints, granite, quartz, porphyry, rock crystal, agates, and many precious stones. It is the substance of which the solid frame of many mountains is composed, and it probably is so of a great part of the globe itself. Its specific gravity is about 2.66. Silix when perfectly pure is a fine powder, hard, insipid, and without smell; rough to the touch, and scratches and wears away glass. When mixed with water, it does not form an adhesive soft mass, and soon falls to the bottom, leaving the water clear. If silix be very minutely divided, it may be dissolved in water to a very small degree.

Although we cannot dissolve silica artificially, we find it done by nature. The Bath waters, and other mineral springs, contain silix in solution in a very small portion. The great springs and waterspouts of Geyser in the island of Iceland, which project the water ninety feet high, contain silix dissolved by some process of nature, for the water falling down deposits such a quantity of silicious earth as to form a sort of cup around the spring. In this process the pressure and heat of the water may, perhaps, greatly contribute to the effect. Silica is a very necessary component part in good mortar. When reduced to minute parts either by nature or art, it is employed in making stone-ware. It is the chief substance of which glass is made, for which purpose it is smelted with the alkaline salts in a great heat. A variety of these salts are used for the purpose, and metals are also frequently employed. Silica, it is probable, is composed of oxygen and a metallic basis.

SILK, the web or envelopment of the caterpillar, of a species of moth called the *Phalena mori*, which being convertible to various purposes of utility and elegance, forms an important article in commerce, as the material of a valuable manufacture. The caterpillar, or silk-worm, when full grown, encloses itself in a loose web, in the midst of which it forms a much closer case or covering, of an oval form, and varying in colour from white to a deep orange, but usually of a bright yellow colour. In this case, or ball, the animal becomes a crystal, and remains enclosed about fifteen days; when having resumed active life, in the form of a moth, it makes a hole at one end of its prison, and comes out. This, as it destroys the silk-ball, is prevented, in those countries where silk is cultivated, by killing the crystalles by means of heat. The culture of silk varies but little in different countries, and does not require any great degree of skill, or considerable capital; and as silk-worms, cherished with care, and attended as matters of curiosity, were found to thrive and multiply in England, it is not surprising that attempts should have been made to establish the culture of it in this country. The success of Henry IV. of France, in extending the culture of silk, which before his time had been confined to a few districts of that kingdom, excited in James I. an active zeal for the introduction of it here. The insurmountable obstacle to raising silk in Great Britain is the climate, which is too cold and wet; and though expedients might be adopted to obviate these inconveniences, they would render the culture of the article, on a large scale, by far too expensive. In the British settlements in the East Indies, the culture of silk has been long established, particularly in the island of Cossimbazar and its neighbourhood, in the province of Bengal; and since, about the year 1760, when the company became the rulers of the country, and adopted a new system of trade for the purpose of realizing the surplus revenue, the culture of raw silk has been promoted, and the quantity considerably increased. Of late years, considerable attention has been paid both to the quality of the silk, and to the mode of reeling it, by which it has been very materially improved, so as to rival, in most respects, the produce of Italy.

SILVER, is the whitest of all metals, considerably harder than gold, very ductile and malleable, but less malleable than gold; for the continuity of its parts begins to break when it is hammered out into leaves of about the hundred and sixty thousandth part of an inch thick, which is more than one-third thicker than gold leaf; in this state it does not transmit the light. Its specific gravity is from 10.4 to 10.5. It ignites before melting, and requires a strong heat to fuse it. The air alters it very little, though it is disposed to obtain a thin purple or black coating from the sulphurous vapours which are emitted from animal substances, drains, or putrefying matters. This coating, after a long series of years, has been observed to scale off from images of silver exposed in churches; and was found, on examination, to consist of silver united with sulphur. Silver is soluble in the sulphuric acid when concentrated and boiling, and the metal in a state of division. The muriatic acid does not act upon it, but the nitric acid, if somewhat diluted, dissolves it with great rapidity, and with a plentiful disengagement of nitrous gas.

SILVERING, performed as gilding, is the application of silver leaf to wood, paper, and other substances.—*To Silver Copper or Brass*, cleanse the metal with aqua fortis, by washing it lightly, and then plunging it into water; or by scouring it

with salt and tartar with a wire brush. Dissolve silver in aqua fortis and copper in the ammonia; this will precipitate the silver in the state of a mercurial powder. Take about twenty grains of aqua fortis powder and mix it with two trachins of tartar in a glass vessel. If ammonia salt and salt a fraction of more put the solution with this composition till they are perfectly white then wash it off and polish it with marine. Amalgam method. Precipitate silver from an ammonia in aqua fortis by copper as before. In half an ounce of this silver and ammonia salt and in ammonia of each two ounces, and use decoction of camomile must make six tins together, make them into a paste with water and mix the copper particles of every kind, and use a wire brush having tartar and ammonia are rubbed. After which they are made for use and polished.—*To ruber leaf plates of Gold.* For each ounce of silver leaf, add in an ounce of common-salt aqua fortis, put them into an earthen jar, place them over a stable fire till the whole is dissolved, then take off the jar, and mix the solution in a pint of clear water; after which, pour it into another clean vessel, to free it from salt or sediment; add a spoonful of camomile salt, and the water which has now a green tinge, will immediately let fall the silver particles, which form themselves into a white earth, pour off the acid, mix the cord with two ounces of salt of tartar, add an ounce of whiting, and a large spoonful of salt, and mix it well up together, when it will be ready for use. Has not cleared the brass from scratches, rub it over with a piece of old hat and rotten-stone, to clear it from all greasiness, and then rub it with salt and water with your hand, take a little of the composition just described on your finger, rub it over where the salt has touched, it will adhere to the brass, and completely silver it. Then wash it well with water, to take off what aqua fortis may remain in the composition; when dry, rub it with a clean rag, and give it one or two coats of varnish, prepared according to the directions already given. This silvering, though not durable, may be improved by heating the article, and repeating the operation till the covering seems sufficiently thick.—*Silver Plating,* the coat of silver applied to the surface of the copper by the means just mentioned, is thin, and not durable. A method more substantial is as follows: form small pieces of silver and copper, tie them together with wire, putting a little borax between, (the proportion of silver may be to that of the copper as 1 to 12;) subject them to a white heat, when the silver will be firmly fixed to the copper. The whole is now passed between rollers, till it be of the required thickness for manufacturing articles of use or ornament.—*To make French Plate,* heat the copper articles intended to be plated, and burnish silver-leaf on it with a burnisher.—*To make Shell Silver,* grind leaf silver with gum-water or honey; wash away the gum or honey, and the powder that remains is used with gum-water, or glaire of eggs laid on with a hair pencil.—*To Silver Looking-glasses,* you must be prepared with the following articles: First, a square marble slab, or smooth stone, well polished, and ground exceedingly true, the larger the better, with a frame round it, or a groove cut in its edges, to keep the superfluous mercury from running off. Secondly, lead weights covered with cloth, to keep them from scratching the glass, from one pound weight to twelve pounds each, according to the size of the glass which is laid down. Thirdly, rolls of tinfoil. Fourthly, mercury or quicksilver, with which you must be well provided; then proceed as follows: the tinfoil is cut a little larger than the glass every way, and laid flat upon the stone, and with a straight piece of hard wood, about three inches long, stroked every way, that there be no creases or wrinkles in it; a little mercury is then dropped upon it, and with a piece of cotton, wool, or hare's foot, spread it all over the foil, so that every part may be touched with the mercury; then keeping the marble slab nearly level with the horizon, pour the mercury all over the foil, cover it with a fine paper, and lay two weights near its lower end, to keep the glass steady, while you draw the paper from between the silver foil and the glass, which must be laid upon the paper. As you draw the paper, you must take care that no air-bubbles be left, for they will always appear, if left in at the first; you must likewise be sure to make the glass as clean as possible on the side intended to be silvered, and have the paper also quite clean, otherwise, when you have drawn the paper from under it, dull white

streaks will appear, which are very disagreeable. After the paper is drawn out, place weights upon the glass, to press out the superfluous mercury and make the foil adhere, when it has run about seven inches in this situation, remove the stone about two or three inches at its nearest end, that as much of the mercury may run off as possible, at a distance two days before you venture to take it up, and before you take the weights off, brush the edges of the glass gently, that as mercury may adhere to them, then take it up, and turn it directly over, with its fore-side upwards, but raise it by degrees, that the mercury may not drop off too suddenly; for if when taken up, it is immediately set perpendicular, air will get in between the foil and the glass at the top, as the mercury descends to the bottom, and your labour will be lost. Another method is to slide the glass over the foil, without the assistance of paper. The methods of silvering glass globes, and the convex sides of looking-glasses for mirrors, are seldom practised, except by very experienced workmen.

SIMARONA, a name given by the Spaniards in America to the bastard vanilla.

SIMARUBA, the bark of the roots of a tree, first imported into Europe in the year 1711. It has since been ascertained to be a species of the quassia, and has been found exceedingly serviceable in many disorders.

SIMIA, the Ape, in Natural History, a genus of Mammalia, of the order Primates. Animals of this genus are commonly divided into such as have no tails; such as have only very short ones; such as have very long ones; and lastly, such as have prehensile tails, with which they can lay hold of any object at pleasure. These four classes are called respectively apes, baboons, monkeys, and apes. In the whole genus there are enumerated by Gmelin sixty-three species, of which we shall notice some of the most important.—*S. satyrus*, or the orang-outang, grows in its native woods of Africa and India, to the height of six feet, and subsists, like most other species, on fruits. It flies from the haunts of mankind, leads a solitary life, and displays great strength, agility, and swiftness, which render it extremely difficult to be taken. It has been known to attack and destroy negroes wandering at a distance from their habitations, and to carry off women to its wretched habitation, watching them with such extraordinary vigilance, as scarcely to admit the possibility of their escape. Its general resemblance to the human figure and countenance is particularly and mortifyingly strong; yet minute observation and dissection have pointed almost innumerable differences, the detail of which is here impossible. It is capable of being tamed and domesticated, and many years one was exhibited in London, which had been disciplined to sit, and work, and eat, like a human being, using a knife and fork for the latter purpose. Its disposition was pensive; its manners were gentle; and it appeared to possess, for its keepers, and those to whom it had been long familiarized, a high degree of genuine gratitude and attachment.—The Barbary ape, is about four feet in height, and is the species most commonly exhibited in public shows, and is trained to the performance of a great variety of tricks, calculated to attract popular admiration. The discipline it passes through is often severe, and this species is considered, in its natural state, as being more ferocious, and less sagacious, than several others of the class. It undergoes accordingly much cruel usage.—The great baboon, is between three and four feet high, of a gray-brown colour, and is particularly muscular in the upper part of its body; its hands and feet have sharp nails, like claws; but on its thumbs there are nails formed like those on the human fingers. It is an animal incapable of domestication.—The dog-faced baboon, is very large, and often greater than the common baboon. It is distinguished by a vast quantity of hair, spreading from each side of the head down the shoulders, and covering the animal to the waist, like a mantle.—The proboscis monkey, is one of the most curious in its aspect, and most ludicrous of the class. It is about two feet in length.—The preacher monkey, is as large as a fox, and is extremely common in the woods of Brasil. Travellers have stated, that it is usual for one of these to ascend a tree, and, by certain sounds, to collect vast multitudes beneath him, when he commences a howl so loud as to be heard to a vast distance.—The royal monkey, is about the size of a squirrel, and inhabits the

damp, woody districts of Cayenne, being never found on the mountains. In its sounds and manners it resembles the last species.

SIMILAR, a composition made of red copper and zinc, in such proportions as to imitate the colour of gold.

SIMILAR Figures, in Geometry, such as have their angles respectively equal, and the sides about the equal angles proportional.

SIMILE, in Rhetoric, is a comparison of two things, which, tho' unlike in other respects, yet agree in the one pointed out.

SIMILITUDE, a striking resemblance between things, which conceals for a time the distinctive marks of individual identity.

SIMITAR, or **SCIMITAR**, a crooked or falcated sword, having a convex edge. It is now rarely used.

SIMONIANS, in Church History, a sect of ancient Christians, so called from their founder Simon Magus, or the magician. The heresies of Simon Magus were principally his pretending to be the great power of God, and thinking that the gifts of the Holy Spirit were venal.

SIMONY, is the corrupt presentation of any one to an ecclesiastical benefice, for money, gift, reward, or benefit; it was not an offence punishable criminally at the common law, it being thought sufficient to leave the clerk to ecclesiastical censures. But as these did not affect the simoniacal patron, none were efficacious enough to repel the notorious practice of the thing. Several acts of parliament have, therefore, been made to restrain it, by means of civil forfeitures, which that modern prevailing usage with regard to spiritual preferments calls aloud to put in execution. By one of the canons of 1603, every person, before his admission to any ecclesiastical promotion, shall, before the ordinary, take an oath, that he hath made no simoniacal contract, promise, or payment, directly or indirectly, by himself or any other, for the obtaining of the said promotion; and that he will not afterwards perform or satisfy any such kind of payment, contract, or promise by any other without his knowledge or consent. To purchase a presentation, the living being actually vacant, is open and notorious simony; this being expressly in the face of the statute. But the sale of an advowson during a vacancy is not within the statute of simony, as the sale of the next presentation is; but it is void by the common law. A bond of resignation is a bond given by the person intended to be presented to a benefice, with condition to resign the same; and is special or general. The condition of a special one is to resign the benefice in favour of some certain person, as a son, a kinsman, or friend of the patron, when he shall be capable of taking the same. By a general bond, the incumbent is bound to resign, on the request of the patron. A bond with condition to resign within three months, after being requested, to the intent that the patron might present his son when he should be capable, was held good; and the judgment was affirmed in the exchequer-chamber; for that a man may, without any colour of simony, bind himself for good reasons; as if he take a second benefice, or if he be non-resident, or that the patron present his son, to resign; but if the condition had been to let the patron have a lease of the glebe or tithes, or to pay a sum of money, it had been simoniacal.

SIMOON. A wind or haze observed by Bruce in the course of his travels to discover the sources of the Nile, which is supposed to be in some respects analogous to the sirocco. It is called by Mr. Bruce the simoom; and from its effects upon the lungs, we can entertain but little doubt that it consists chiefly of carbonic acid gas in a very dense state, and perhaps mixed with some other noxious exhalations.

SIMPLE, in Music, a term applied to that counterpoint in which note is set against note, and which is called simple, in opposition to the more elaborate composition, known by the name of figurative counterpoint.

SIMSON, ROBERT, a celebrated mathematician, born in the county of Lanark, and educated at Glasgow. He died at the age of eighty-one.

SIN, in Theology, a want of conformity to the will of God, which comprehends sins of omission and sins of commission. Sins are distinguished by the terms *original* and *actual*; the former is the morally contaminated nature we derive from our primary progenitors, and the latter arises from our personal disobedience.

SINAPIS, **MUSTARD**, a genus of plants belonging to the class of tetradynamia, and to the order of siliquosa, and in the natural system ranged under the 39th order siliquosa.

SINAPIS, in Gardening, contains plants of the hardy, herbaceous, annual kind, of which species those most cultivated are, the white and black mustard.

SINCERITY, in Ethics, that excellent habitude and temper of mind which gives to virtue its reality, and makes it to be in reality what it appears.

SINE, or *Right Sine of an Arch*, in Trigonometry, is a right line drawn from one end of that arch, perpendicular to the radius drawn to the other end of the arch; being always equal to half the chord, or twice the arch.

SINECURE, is where a rector of a parish has a vicar under him endowed and charged with the cure, so that the rector is not obliged either to do duty or residence.

SINE DIE, in Law, a phrase which signifies, that judgment being given for the defendant, he is dismissed the court. The phrase is also used in parliament when a debate is adjourned, and no day fixed for its resumption. This is considered as a polite way of dismissing it altogether.

SINEW, in Anatomy, properly denotes what is called a nerve, though, in common speech, it more generally signifies a tendon. The Jews will not eat the sinew of the thigh of any animal, in memory of the sinew of Jacob's thigh, which was touched by an angel.

SINGING, the art of making divers inflexions of the voice, agreeable to the ear, and corresponding to the notes of a song, or piece of melody.

SINKING FUND, a portion of the public revenue set apart to be applied to the reduction or discharge of the public debts. The appropriation of a part of the revenue to this purpose is a measure which had been adopted in other countries, long before any necessity for it existed in England; a provision of this kind having been established in Holland in 1655, and in the ecclesiastical state in 1685.

SINUOSITY, a series of bends, curves, or other irregular turns and figures; sometimes rising, sometimes sinking, such as is described by the motions and contortions of serpents, the windings of rivers, and the indentations and projections of the sea-coast.

SIPHENIA, in Botany, a tree from which issues a resinous exudation so well known under the appellations of caoutchouc, elastic gum, and Indian rubber. For the manner in which Indian rubber is made, see **CAOUTCHOUC**.

SIPHON, or **SYPHON**, in Hydraulics, a bended pipe having the air sucked out of it, and, with one end placed in a vessel containing any liquid, is used to draw off the liquor at the other.

SIPHURIUS LAPIS, a steatite substance, found in the island Siphnos, in the Ægean sea, and dug up in large masses near the coast. This substance being soft when found, was easily wrought into various kinds of vessels, which, being burnt and oiled, became black, solid, susceptible of a fine polish, and capable of enduring a great degree of heat. Under the name of Lapis Lebitum, the same substance is still known in many parts of Europe. In its native state, it is said to resemble the soap rock.

SIPONCULUS, or **TUBE-WORM**, a genus of insects of the order vermes intestina; the generic character is, body round, elongated; mouth cylindrical at the end, and narrower than the body; aperture at the size of the body, and veruciform.

SIREN, in fabulous history, the *Mermaid*; and sometimes the term is applied to imaginary sea nymphs, or sea sorceresses, who allure mariners to their fate.

SIREN, in Natural History, a genus of Amphibia, of the order reptiles, or of the order meantes, an order instituted by Linnaeus on account of this genus of animals alone. The eel-siren is most nearly allied to the lizard tribe, but differs from it in having only two feet, and those armed with claws; the body is shaped like an eel; its colour is a dark brown speckled with white; it is often more than two feet long, and inhabits the stagnant waters of South Carolina; sometimes, however, quitting water for the land.

The anguine siren, is a native of a particular lake in Carniola, from which the water regularly drains off during the summer; during which time the bottom produces corn or pasture. In

In autumn the water returns with considerable rapidity, flowing principally from springs in the neighbouring fountains. In this lake this siren is found of the length of eleven inches, and of a pale rose colour. It has both fore and hind legs. Its movements are extremely slow and weak when it is placed in a vessel, either with or without water; but in its native situation it is far more active. It is by some supposed to be the larva of a lizard, and by others imagined to be a complete animal. Its habits are predatory, and it subsists on the smaller inhabitants of the water.

SIRI, among the Romans, were subterraneous vaults or caves, in which wheat could be kept sound and fresh for fifty years.

SIRIUS, in Astronomy, the dog-star in the constellation of Canis Major, south-east of Orion. It is the most brilliant star that appears in the heavens, and is therefore thought to be nearer to us than any other. See **ORION**.

SIROC, or **SIROCCO**, a periodical wind which visits Italy, Dalmatia, and Sicily about Easter. It is attended with such a strong degree of heat, that at Palermo it has been compared to a blast of burning steam, issuing from the mouth of a hot oven. It rarely continues at one visit more than forty hours, but during this time, the inhabitants remain within their houses, otherwise life would be scarcely supportable. Its effects are debilitating, but it has not been accused of generating any particular disease.

SITE, or **SCITE**, denotes the situation of a house, messuage, mansion, village, or town, and not unfrequently the ground on which either is supposed to stand.

SKATE, a sort of shoe armed with a strong rib of steel, for sliding on the ice. The exercise of skating, carried to a certain degree of perfection, surpasses all other pastimes, in the beauty of its movements, and the variety and rapidity of its graceful attitudes. The dexterity with which an experienced skater will pass through his numerous and intricate evolutions is truly astonishing; and to those who are not intimately acquainted with the laws of gravitation, his surprising agility has all the appearance of enchantment. To those who begin when young, under the tuition of an experienced skater, the exercise is learned with great facility. It cannot, however, be denied, that it is frequently attended with danger, for scarcely a winter passes in which, through the breaking of the ice, several lives are not lost. Some skaters have been known to travel fifteen miles an hour.

SKEET, a sort of long scoop used to wet the sides of a ship, in order to keep them cool, and prevent them from splitting by the heat of the sun. It is also employed in small vessels, to wet the sails, to render them more efficacious in light breezes: this operation is sometimes performed in large ships by means of the fire-engine.

SKELETON, all the bones of a dead animal, dried, cleansed, and disposed in their natural situation.

SKIDS, or **SKEEDS**, long compassing pieces of timber, formed to answer the vertical curve of a ship's side. They are notched below, so as to fit closely upon the wales, and extend from the main-wale to the gunnel, being strongly nailed to the side. Their use is to preserve the plank of the side when any weighty body is hoisted or lowered against it.

SKIFF, a small light boat, resembling a yawl; also a wherry without masts or sails, usually employed to pass a river.

SKIM COULTER, in Agriculture, a sort of coulter invented by Mr. Duckett, for paring off the surface of coarse grass or other lands, and placing it in the bottom of the furrow, so as to be fully covered and secured. This coulter is connected with the plough that turns the furrow.

SKIM MILK, that sort of milk which is left after the cream has been taken off its surface.

SKIM MILK CHEESE, an inferior kind of cheese made from skimmed milk.

SKIN, in Anatomy, a large thick membrane spread over the whole body, serving as an external organ of feeling, and as an ornament and covering to the parts beneath.

SKIN, in rural economy, is the hide of any animal, and is applied to numerous purposes besides its principal one, that of being made into leather.

SKIRMISH, in War, an irregular kind of combat between

small parties in sight of their respective armies. These combats are sometimes directed thus to advance, and commence an encounter, in order to bring on a general engagement.

SKULL, that part of the head which forms its great bony cavity.

SKY, the blue expanse with which the globe is encircled. The azure colour of the sky Sir Isaac Newton attributes to vapours beginning to condense therein, which have consistence enough to reflect the more violent rays, but not enough to reflect the less reflexible ones.

SKY SCRAPERS, small triangular sails, sometimes set above the royals; they are, however, very rarely used.

SLAB, an outside sappy plank or board sawed off from the sides of a timber tree: the word is also used for a flat piece of marble.

SLAB LINES, small cords passing up behind a ship's main-sail or fore-sail, and being reeved through blocks attached to the lower part of the yard, are thence transmitted each in two branches to the foot of the sail, where they are fastened. They are used to truss up the sail, but more particularly for the convenience of the steersman, that he may look forward beneath it.

SLACK OF A ROPE, that part which hangs loose, as having no strain or stress upon it. *Slack Rigging*, implies that the shrouds, stays, &c. are not so firmly extended as they ought to be. *Slack in Stays*, signifies slow in going about. *Slack Water*, the intervals between the flux and reflux of the tide, or that time during which the water apparently remains in a state of rest.

SLAG, denotes vitrified cinders. In some places it is used in buildings, and in repairing roads.

SLAKE, the saturating of quicklime with water, or other moisture.

SLAKED LIME, such as is reduced to a state of powder by the action of water upon it, or the hydrate of lime. In this case the lime is combined with about one-third of its weight of water.

SLAKEN, in Metallurgy, a term used by smelters to express a spongy semivitrified substance, which they mix with ores of metal to prevent their fusion. It is the scoria, or *scum*, separated from the surface of a former fusion of metals.

SLAM, the refuse of alum works, which is used as a manure, mixed with sea-weed and lime, in Yorkshire.

SLAP-DASH, in Building, provincially rough casting. It is a composition of lime and coarse sand reduced to a liquid state, and applied to the exterior of walls, as a coating that is both preservative and ornamental.

SLATCH, the period of a transitory breeze, or the length of its duration.

SLATE, a well-known, neat, convenient, and durable material for the covering of the roofs of buildings. There are great varieties of this substance, and it likewise differs very greatly in its qualities and colours. In some places it is found in thick lamina, or flakes, while in others it is thin and light. The colours are white, brown, and blue. It is so durable in some cases as to have been known to continue sound and good for centuries.

SLAVES and SLAVERY. Slavery, in its proper and detestable signification, is a system which gives to the master an absolute power over the destiny and life of the slave. By the laws of England, and the uncorrupted feelings of Englishmen, it is held in the utmost abhorrence; nor is it suffered to pollute our atmosphere or soil. The instant a slave puts his foot on British ground, the laws take him under their protection, and he is declared free. Yet, unhappily, it still continues in our West India islands, to the disgrace of the British name; and in other countries, to the lasting reproach and dishonour of human nature.

SLAZY HOLLAND, a slight Holland, thus called because made in Silesia, in Germany. The texture being thin, all slight, ill-woven Hollands have obtained the name of slazy.

SLEDGE, a kind of carriage without wheels, for the conveyance of very weighty things, as huge stones, &c.

SLEEP, in Physiology, the greater or less suspension of the functions of sensation and volition. The phenomenon of sleep has given rise to many curious speculations, inquiries, and theories; but its real nature is better known from fact and experience, than from any philosophical investigations.

SLEEPERS, in a Ship, timbers lying before and aft, in the bottom of the ship, as the rung-heads do; the lowermost of them is bolted to the rung-heads, and the uppermost to the futtocks and rungs.

SLEEPERS, a name given to some animals that sleep during the winter, such as bears, marmots, dormice, bats, hedge-hogs, &c.

SLEEPERS, in the glass manufactories, are large iron bars crossing the smaller ones, and hindering the passage of the coals, but leaving room for the ashes to descend.

SLEEPERS, among Carpenters, are pieces of wood to support joists, also a name formerly given by shipwrights to the thick stuff placed longitudinally in a ship's hold, opposite to the several scarfs of the timbers, but now generally applied to the knees which connect the transoms to the after timbers on the ship's quarter. They are particularly used in Greenland ships, to strengthen the bow and stern-frame, to enable them to resist the shocks of the ice.

SLICH, the ore of any metal, particularly of gold, when it has been pounded and prepared for further working.

SLIDE-BUTT, in Agriculture, a sort of sledge in the form of a strong oblong box, shod underneath with thick pieces of timber. It is chiefly used for drawing manure from place to place, but chiefly in fields. It will contain about three wheelbarrows' full. Sometimes the butt has wheels, and when this is the case it is called *gurry*.

SLIDING, in Mechanics, is when the same point of a body, moving along a surface, describes a line without revolving.

SLIME, a soft muddy substance left by tides and other waters, in different places, which, mixed with other materials, become an useful manure.

SLING, an instrument serving for casting stones with great violence. The inhabitants of the Balearic islands were famous in antiquity for the dexterous management of the sling; it is said they bore three kinds of slings, some longer, others shorter, which they used according as their enemies were nearer or more remote. It is added that the first served them for a head-band, the second for a girdle, and that a third they constantly carried with them in hand.

SLINGING, is used variously at sea, but chiefly for the hoisting up casks, or other heavy things, with slings.

SLINGS, a rope fitted to encircle a cask, jar, bale, or case, and suspend it while hoisting and lowering. Of these there are various sorts, according to the weight or figure of the object to which they are applied. *Slings of a Yard*, ropes fixed round its middle, and serving to suspend it for the greater ease of working, or for security in an engagement; in the latter case they usually add iron chains to the slings of the lower yards. This term also implies the middle, or that part of the yard on which the slings are placed. *Boat-Slings*, strong ropes, furnished with hooks and iron thimbles, whereby to hook the tackles, in order to hoist the boats in or out of the ship, the hooks of the slings being applied to ring-bolts fixed in the keel and extremities of the boat. *Butt-Slings*, are those used in lading and delivering ships, and are nearly in the form of a pair of spectacles.

SLIP, a place lying with a gradual descent on the banks of a river, or harbour, convenient for ship-building.

Ship SLIP, *Morton's Patent for Hauling Vessels out of the Water for Repairs*, &c.—A carriage is constructed, as represented in the plan, p. 944, with truck-wheels to run upon the iron railways of the inclined plane, these truck-wheels having flanges to guide them. Blocks are laid upon the keel-beam of the carriage, to a sufficient height, so that the keel of the vessel clears the ends of the cross pieces; and each block embraces four trucks—two on each side of the beam. The blocks which slide upon the cross pieces, are made up to correspond to the rising of the vessel's bottom. These blocks are run out to the extremity of the cross pieces, and their ropes, crossing the carriage, are reeved through a sheave attached to the opposite cross piece, up to the top of the rope rod. The shores (if any are necessary) are put into their places, turn upon a joint at their heel, and are secured (while the vessel is floating on,) from falling outwards by a small chain. The carriage, thus prepared, is let down the inclined plane generally at low water, but if found expedient, into the water, (as the weight of the metal attached thereto keeps it down in its place,) sufficiently

far to allow the vessel to float upon it. The chain-purchase is attached to the carriage: and a water-staff is placed at the fore-end of the keel-beam, to mark the depth of water, and be a guide in floating the vessel on. The vessel is brought to the end of the carriage, and hauled over it, (having bow and quarter lines to steady her,) till her fore-foot, or advanced part of the keel, takes the blocks between the fore-foot guides. The ends of the sliding block-ropes are now taken from the rods on board, but kept slack; she is still hauled forward as the water flows, until the keel takes the blocks at the contracted part of the guides, which are just wide enough to receive it. Being still afloat abaft, having been previously so trimmed,) the vessel is then adjusted over the blocks abaft by the water line. When the iron guides are hauled up, they will confine her to settle down truly. By heaving the purchase, she will soon take the blocks abaft, which is observed by the water-mark left on her bottom; she is trimmed upright, and the foremost bilge, or sliding-blocks, hauled in tight. As she rises out of the water, each succeeding block is hauled in, but not till the weight of the vessel has settled well on her keel. The sliding-blocks are prevented from springing back, by their palls falling into their racks; the shores are brought to her sides, and cleared. When thus secured, she is hauled up the inclined plane, at the rate of from 2½ to 5 feet per minute, by six men to every hundred tons. Being hauled up, she is shored from the ground; the keel-beam is secured from moving; and the sliding-blocks, with their cross pieces, are in a few minutes removed, when the vessel is ready to be repaired. The blocks being relieved of the vessel in the usual manner, the keel beam, with the after cross beams, will run from under her. The carriage is again put together, and another vessel can be hauled up astern of the former. When a vessel is to be launched, the cross pieces, with their blocks, are put under her, and instantly let into the water; or, to launch and haul up vessels the same tide, temporary blocks are put under the bottom of the vessel to be launched upon the cross pieces, instead of the sliding blocks, which are prepared as before, to suit the bottom of the vessel to be taken up; the vessel is launched; when she, and the temporary blocks which steadied her, float from the carriage, and the other vessel is taken on, and hauled up as formerly.

Advantages of this Invention.—1st. The vessel being above ground, the air has a free circulation to her bottom, thereby requiring no firing; the men work with much more comfort, of course quicker, and in winter, particularly, they have night better and much longer, than within the walls of a dry dock; considerable time is also saved in carrying and removing the materials for repairing the vessel.

2nd. Such is the facility of its operation, that ships can be hauled up, inspected, and even get a trifling repair, and be launched the same tide; and the process of repairing one vessel is never interrupted by hauling on another, as is the case in dry docks, from the necessity of letting in the water.

3d. The vessel is hauled up the inclined plane at the rate of 2½ to five feet per minute, by six men to every hundred tons; so that the expense of hauling up and launching a vessel from 200 to 300 tons, does not exceed thirty shillings. 4th. A slip can be constructed at about one-tenth the expense of a dry dock, and be laid down in situations where it is impossible to have a dock built.

4th. There is no previous preparation, or fitting bilge-ways, necessary.

The chain of the mechanical power is attached solely to the carriage on which the vessel is floated; therefore the vessel is exposed to no strain. The whole apparatus can be removed from one place to another, and be carried on ship-board.

Description of the Drawings.—A, A, A, A, side beams of the carriage, with trucks or rollers beneath, at each cross piece; B B, B, B, sideways; c, c, c, c, c, c, cross pieces; c', c', cross-pieces, which racks; c'' c'', aftermost cross pieces; b, b, braces, g, g, iron guides; b', b', oblique braces; g', g', guides to receive the fore-foot of the vessel; s, s, s, s, s, s, s, s, sliding blocks; r, sliding-block rope; s', s', shore; r', r', rope for hauling guide or crutch, M, midway, with rack; N, N, main or keel beam of the carriage; P, purchase; W, wheel or pinion, capstan, or other purchase; S, large stones; C, chain; K, keel of the vessel; G, guide for the after-part of the keel; p, rack-pall; R, R, inclined

plane, road, or platform, laid nearly with the same slope as the

slips commonly used for building ships; fig. 1, plan of the slip

and carriage. Fig. 2, side view of the ship. Fig. 3, stern view. Fig. 4, head view.

At Stohcross, a little below the new Quay on the Clyde, at Glasgow, there is a slip on Morton's principle, but differing a little in the application. The vessel is there made to rest on the bilge, or under part of the bottom, instead of the keel, as in the above plan; by this means she requires less water to raise her on the carriage, as the groove between the iron rail-ways admits the keel, and allows it to move up and down freely, without requiring any support. The carriage consists of two separate beams resting on the rail-ways, without any intermediate keel-beam or cross pieces to connect them; to the ends of both are attached two connected series of iron rods, and two chains by which they are drawn up the inclined plane.

SLIPS, in Gardening, such portions of plants as are slipped off from their parent stems for planting out as sets.

SLOATH, or **SLOTH**, the name of an animal remarkable for the slowness of its motion, whence its appellation. Of this animal there are three species. It is about the size of a fox, and is a native of South America, and of Ceylon in India. It requires three or four days to ascend a tree and descend from it; and on level ground, about fifty paces is a day's journey: its food is fruit, and the leaves of trees.

SLOE, *Prunus Sylvestris*, the English name for the wild plum. The juice expressed from this fruit while unripe, and insipidated by a gentle heat to dryness, is called German acacia. The bark both of the branches and roots, in intermittent fevers, is said to be little inferior to the Peruvian bark. The flowers made into a syrup and sweetened with sugar, is a good purgative for children. Tea is frequently adulterated with the leaves.

SLOOP, in Naval affairs, a small vessel furnished with one mast, the main-sail of which is attached to a gaff above, to the mast on its foremost edge, and to a boom below; it differs from a cutter by having a fixed steering bow-sprit, and a jib-stay; the sails also are less in proportion to the size of the vessel. Sloops of war are vessels commanded by officers of a middle rank between a lieutenant and a post-captain; these are styled masters and commanders. They carry from ten to eighteen guns, and are variously rigged, as ships, brigs, schooners, and sometimes cutters.

SLOPS, a name given to clothes for seamen.

SLOWWORM, a species of innoxious serpent, sometimes called the blind worm, and sometimes the deaf adder.

SLUG, in Gardening, a destructive kind of snail, eating off the leaves and buds of tender plants. There are various kinds, but all are highly mischievous to the gardener and farmer.

SLUICE, in Hydraulics, a frame of timber, stone, earth, &c. serving to retain and raise the water of the sea, a river, &c. and on occasion to let it pass.

SLUICE, SELF-ACTING, for Mills, or an Hydraulic Apparatus, for regulating the Supply of Water to Mills, by Mr. Robert Thom, of Rothesay Mills, near Glasgow.—The drawings, in the Plate, exhibit no less than five distinct and separate operations; that is, each figure in the drawing is a complete apparatus of itself, applicable to different purposes, or under different circumstances, from any of the other drawings. The apparatus, fig. 10, which, on account of the variety of operations it has to perform, appears more complicated than any of the others, is, notwithstanding, very simple when executed on a large scale. The advantages derived from the adoption of these inventions are many; as they relieve us from all anxiety and care respecting the waste of water, and the damages done to banks and other grounds by its overflow; and the exact quantity of water required by the works is always sent down, and no more; two steam-engines of thirty-horse power have been superseded at Edinburgh by their adoption; the yearly saving thereby is above six hundred pounds sterling.

Explanation of the Plate.—The lever sluice, fig. 1. This sluice, when placed on a reservoir that supplies any canal mill, or other work, with water, (where the aqueduct between the reservoir and such work is on a level,) will always open of its own accord, and let down the quantity of water wanted by such work, and no more; that is, when water is wanted it will open, and when not wanted it will shut; so that it not only supercedes the water-man, but saves a great deal of water. A B, a tunnel through which the water passes from the dam to C D, the aqueduct that carries the water to the mills. E, a float that rises and falls with the water in the aqueduct. F, an aperture in the mouth of the tunnel. G, the self-acting sluice that opens and shuts aperture F. H I, a lever which turns upon fulcrum K, and is connected at one end with sluice G, and at the other with float E. The sluice G is here represented open, as when the mills are going, but when the sluice is shut that lets the water on the mill wheel, the water in the aqueduct rises, and with it float E, which raises the end I, and lowers the end H of the lever H I, and shuts sluice G. When the water is again let upon the wheel, the surface of the aqueduct falls, and with it the float, which opens sluice G as before. Upon the lever H I there is another small lever L M, which turns upon fulcrum M, and has the weight N suspended to the other end L. In the ordinary working of the apparatus this lever is quite stationary, and produces no effect whatever; but during floods, the aqueduct is swelled by streams that run into it between the reservoir and the mills, and when this happens when the mills are not at work, the water, by pressing up one end of the lever when the other cannot get down, would strain or break the apparatus. But, in such cases, the extra pressure raises the small lever, which takes all strain off the other parts; that is, the weight N requires more force to lift it than is required to shut the sluice; and therefore will not move till that takes place; but when the extra strain is continued after the sluice is shut, the lever and weight then rise with the float. The dimensions of the float are nineteen feet square by seven inches deep; the lever is twenty-seven feet long, being twice the length between the fulcrum and the sluice, that it is between the fulcrum and the float. The sluice is three feet three inches long, and fifteen inches deep; but it requires to be raised only seven inches (when the water in front is three feet high) to pass as much water as gives a power of forty horses to a water wheel, the fall there being twenty feet. To determine the proper dimensions of the float and relative lengths of the ends of the lever, it was necessary to ascertain how far the sluice required to be raised, to pass the quantity of water wanted; and also how far the water in the aqueduct might be raised above the height required to supply the works: the first was found to be seven inches, and the last only four inches. The end of the lever connected with

* From the Transactions of the Society of Arts, &c. vol. xl.—The Society presented their large Silver Medal to Mr. Thom for this communication.

*Mr. Thomas Apparatus for
regulating the supply
of water to mills.*

the float was made, therefore, only half the length of the end connected with the sluice; and the float was made of such dimensions, that, when sunk half an inch in water, the weight of water thereby displaced was equal to twice the weight required to shut the sluice with an equal lever. When, therefore, the water in the aqueduct rises upon the float half an inch higher than it sinks by its own weight, the sluice begins to move; and by the time the water rises other three and a half inches, the sluice is of course seven inches down, or shut. This apparatus has now been working at Rothesay five years.

The water sluice, fig. 2. This sluice, when placed upon any river, canal, reservoir, or collection of water, prevents the water within from rising above the height we choose to assign to it; for whenever it rises to that height, the sluice opens, and passes the extra water; and whenever that extra water is passed, it shuts again; so that whilst it saves the banks at all times from damage by overflow, it never wastes any water we wish to retain. A B part of a canal, river, stream, or collection of water. C D high water mark, or the greatest height to which the water is allowed to rise. E F a sluice, or folding-dam, which turns on pivots at F. G a hollow cylinder, having a small aperture in its bottom, from which proceeds the pipe H I. K another cylinder, water-proof, that moves up and down within the former cylinder. L a pulley, over which passes a chain attached to the sluice and to the cylinder K. When the water in the canal or river rises to the line C D, it passes into cylinder G at the small holes M M, and this lessens the weight of cylinder K so much, that the pressure of the water in front of sluice E F throws it open. When the water subsides, and no longer runs in at the small holes in cylinder G, that cylinder is emptied by the small pipe H I at its bottom, which is always open, and then the weight of cylinder K shuts the sluice as before. An apparatus of this kind was first erected at Rothesay in 1817. The dimensions of one of these are, K, two feet diameter and two feet deep, over all: weight 500 lbs. G, five feet ten inches deep and two feet one inch diameter inside. E F, four feet long and two feet deep, but the cylinders are powerful enough to work the sluice six inches deeper. This sluice may be made with pivots to turn at the top, bottom, or middle: it may also be placed at the surface or bottom of the water, or any intermediate space, or right below, as suits the particular case; the cylinders may also be placed as shown in fig. 3, without the reservoir; that is, on the outside, or behind the dam or embankment, by having a pipe N N to communicate between the upper part of the canal or reservoir and the cylinder. In this case, the chain passes over two pulleys, and is attached to an arm projecting from the back of the sluice. By adopting this principle, a self-acting dam may be raised in any river or stream, up to high-water mark, by which means a considerable reservoir will be obtained, whilst during floods the dam will fold down, and no new ground be overflowed. In lawns or pleasure-grounds, through which streams or rivulets flow, these sluices might be applied to advantage; for, by placing one on the bank of each pond, the water within would always be kept at the same height, let the weather be wet or dry; and, therefore, flowers and shrubs might be planted close to the water's edge, or in it, as best suits their respective habits, and their position with regard to water would always be the same.

The double-valve sluice, fig. 4. This sluice answers the same end as the lever sluice, but is more applicable in cases where the reservoir is deep, and the embankment consequently large. It also answers the purpose of the waster sluice, as it opens and passes the extra water, whenever it rises in the reservoir the least above the height assigned, and of course supersedes a by-waste. In making hydraulic experiments, this sluice will also be found of considerable importance, as, by keeping the cistern from which we draw the water for the experiments always exactly at the same height, it will not only save intricate calculations, but make the result on the whole more correct. A, part of the tunnel through which the water flows from the reservoir to B C, the aqueduct that conveys the water to the mills. D E a sluice that turns upon pivots at D. F G a hollow cylinder; H another cylinder, water-proof, of rather less specific gravity than water, and which moves up and down freely in cylinder F G: a chain, one end of which is fixed to an arm

attached to sluice D E, and the other to cylinder H, passes over pulleys I and K; L a cistern always full of water, being supplied by a spring; G M a pipe that communicates between cistern L and cylinder F G; N O the required level of the water in aqueduct B C; P a float which rises and falls with the water in aqueduct B C: attached to this float is a spindie carrying two valves, which by the descent of the float close the aperture in the lower end of pipe M, and open the communication between M and the cistern L. When the float P, and consequently the attached valves, rise, indicating a sufficiency of water in B C, the water escapes from the cylinder F G, because the lower aperture in M is opened, and the upper, which communicates immediately with the cistern L, is closed; as shewn on a larger scale, fig. 6. The sluice D E, fig. 4, is represented shut, cylinder F G empty, cylinder H at the bottom of F G, and the water in the aqueduct at its greatest height. Suppose now, water to be drawn from the aqueduct for any purpose, the float P will fall with the water, and with it the valves. The water now flowing into F G from L will be retained; H will be deprived of its weight, and consequently of its action on sluice D E, which will then yield to the pressure of the water in the reservoir, and pass the requisite quantity, till the float P rising to its former level, opens the lower valve, and shuts off the communication between L and M; the cylinder F G then empties itself, and the weight H closes the sluice. In order to make this sluice operate also as a waster sluice, a tube is made to communicate between the reservoir and cylinder F G; this tube, which must necessarily supply water to F G faster than it can escape by the valve in the lower end of M, enters the reservoir at the height to which we wish to limit the rise of the water, and whenever it rises so as to flow into this tube, the cylinder F G is filled, and the sluice D E opens, and passes the extra water so long as the supply continues through the tube to the cylinder F G; when that ceases by the subsiding of the water in the reservoir to its limited height, the sluice D E shuts as before. The axis of motion of this sluice, instead of being placed at the top, may be placed a little above its centre of pressure, as shewn in fig. 7. In this case, the whole of the operations before described will be reversed: the weight of cylinder H will tend to open the sluice, and the pressure of water in the reservoir to shut it; the rise of the float P, instead of opening the lower aperture of M, will close it, and open the communication with the cistern L, as shewn in fig. 8, the consequence will be, that the cylinder H will be deprived of its weight, and the sluice will be closed by the pressure of the water in the reservoir. In this case, the axis of motion is placed just so far above its centre of pressure as to allow the extra pressure below to overcome the friction, and shut the sluice when cylinder H is floated: this cylinder need only be heavy enough to overcome twice the friction. In order to open the sluice when the water is drawn from cylinder F G; I have found the friction in this case to be less than one-fiftieth of the weight of the column of water pressing upon the sluice; but to guard against contingencies, the machine is made powerful enough to act, although the friction were to become one-tenth, which from the nature of things is more than it can ever be. An apparatus on this construction was erected at Rothesay, in 1819, and has been in constant use ever since.

The single-valve sluice, fig. 9. The construction of this sluice is nearly the same as the last, only it is applicable in cases where the reservoir is on high grounds above the works requiring the water; and where, of course, the water passes down a declivity. A B part of the tunnel of a reservoir; C D a sluice that turns upon pivots at C; E F the rivulet that carries the water from the reservoir down to G H, part of a level canal or aqueduct. I is a hollow cylinder; K another cylinder, water-proof, of rather less specific gravity than water, which moves freely up and down within cylinder I; L a pulley, over which passes a chain attached at one end to the sluice, and at the other to the cylinder K; M, a small cistern kept always full of water, either by a small hole below the sluice, or by the waste from the sluice; a small pipe communicates between this cistern and the upper part of cylinder I; N O, another small pipe, communicating under ground between cylinder I and a valve at the lower end of O, which is closed by the descent of the float P; the float is placed within a small pool of water on the same

level as, and communicating with, the canal. The water in the canal is represented as at its greatest height, the valve opened by the float P, the cylinder I empty, because the valve at O passes the water faster than it is supplied from the cistern M; the cylinder K is consequently at the bottom of I, and the sluice is closed. When the surface of the water falls in the canal, the float P falls with it, the valve at O is closed, the cylinder I is filled, and K floated, the sluice CD opens by the pressure in the reservoir, and supplies water till the canal GH acquires its proper height. The mode of producing this effect may be varied, as in the last instance, by hanging the sluice on pivots a little above the centre of pressure, so that it shall be kept closed by the weight of the water in the reservoir, and opened by the descent of cylinder K; the valve at O will then require to be shut by the ascent of the float P. It is of no consequence, therefore, in regard to regulating the supply of water, how far the reservoir is from, or how high above, the level of the works requiring the water, save that the length of the pipe NO must correspond with the distance, and its strength with the height or pressure of the water; it is necessary, however, that the bore of this pipe should be small, particularly where its length is considerable, in order that the sluice may open or shut in a short time after the valve at O opens or shuts, and at the same time require only a small supply of water for cistern M, as that supply must always flow, whether it be otherwise needed or not. Suppose, therefore, the opening into pipe NO from I to be only half an inch bore, and that the valve at O is shut, it is evident when that pipe is empty, that the sluice CD will not open (or shut, if being on pivots placed just above the centre of pressure) till both the pipe NO and cylinder I be filled; and that the smaller the bore of that pipe, the sooner will it be filled. The time, therefore, that sluice CD takes to open (or shut, as the case may be) after the valve at O shuts, will always be the same that the pipe NO and cylinder I take to fill; and to make sluice CD take an equal time to shut (or open, as the case may be) after the valve at O opens, the aperture of that valve must be such as to take an equal length of time to run off the water to the bottom of cylinder I, (while the water is still flowing from cistern M,) as the pipe from cistern M takes to fill both cylinder I and pipe NO, when the valve at O is shut.

The chain sluice. This apparatus answers exactly the same purpose as the last, but the construction is somewhat different; that difference is described by dotted lines in connexion with the last figure, of which let all the parts be supposed to remain except the pipe from the cistern M, the pipe NO, and the float P. A pipe *m* communicates between cistern M and the upper end of cylinder *no*, from the lower end of which proceeds a pipe *p* connected with the bottom of cylinder I; an aperture in the lower extremity of *no* is supplied with a valve opening downwards loaded with a weight *q*, and attached to a rod suspended from the end of a lever *rs*, moving on a fulcrum at *t*; a chain passing round two pulleys *u* and *v* connects the other end of this lever with a float *w*, of sufficient weight to overcome the loaded valve *q*. To apply this apparatus where the sluice is hung on pivots just above the centre of pressure, no change is required but that of making the valve *q* open upwards. This construction may, perhaps, be adopted with advantage on account of its cheapness, where the reservoir is very near the level canal, but a considerable height above it; as a brass wire one-tenth of an inch diameter will be strong enough for the chain where the distance is short, it having in any case little more to lift than twice its own weight; the former method using the pipe NO instead of the chain, seems better adapted to general purposes.

The double weather sluice, fig. 10. This apparatus is designed for what are generally called compensation reservoirs, where we are only allowed to retain the surplus water of floods, the rivulet or stream being allowed to flow at all other times the same as if no reservoir were there. The usual way of doing this, which may be understood by reference to fig. 5, is to cut an aqueduct, AFB, round the reservoir C, along which all the water of the stream is carried past the reservoir, except during floods, when a part runs over at the by-wash F into the reservoir. But before any part is thus allowed to run over, the proprietors below at Z must have all they need; and then the rise that sends part into the reservoir, sends also more down

the aqueduct; this additional part sent down is therefore lost. But the same rains that swell the streams above the reservoir, also swell the streams GHI and K between the reservoir and place below at Z, where the greatest quantity of water may be needed; all this additional water from the streams below, is therefore also lost. By adopting this apparatus, all that waste is saved, or retained in the reservoir; so that whilst the proprietors below have, in all ordinary times, the same water as if no reservoir had been made, we retain in the reservoir, during floods, all the water not then needed below. A is a basin of water, behind a reservoir, in which the water is always kept at the same level by the apparatus, fig. 4. B, one of a number of sluices of the same kind on that basin. C, a can, open at the top, and having a very small aperture in the bottom; a chain passes over pulley D, having one end fixed to the arm E, attached to sluice B, and the other to can C. F, a weight that keeps the sluice B always shut, when the can C is empty: when that can is full of water, it lifts the weight F, and opens the sluice. GH, a section of that part of the rivulet immediately before it falls into the reservoir. IKL, a pipe, which communicates between the rivulet at GH, and the can C. When the water in the rivulet GH is so low only as to flow through aperture 1, then, all that water passing down pipe IKL, flows out at M into can C, which being thus filled with water, opens sluice B, and passes as much water as the rivulet then brings into the reservoir. But when the rivulet swells so as to flow out at aperture 2, then the opening at M not being able to pass the whole, the water rises in pipe IK, and passes along pipe NOP, and falling into another can,* opens a second sluice, which, with the first, passes as much water as the rivulet then brings into the reservoir. When the water in the rivulet rises so as to flow out at aperture 3, it rises also in IK, and passing along pipe QRS, flows out at S into a third can, and opens a third sluice; and these three pass as much water as the rivulet then brings, and which is here supposed to be the greatest quantity wanted at the place Z, fig. 5. Suppose now the flood should still continue to increase; then the streams and surface water between the reservoir and Z will increase the rivulet at Z, as well as the higher streams increase it at GH; but there was previously enough of water at Z; when, therefore, the rivulet rises so as to flow out at aperture 4, the water will rise also in the vertical tubes M, P, and S, which are respectively surmounted with wide hollow cylinders, T, U, and V, containing the water-pipe floats W, X, and Y. The water first rises to float W, which it lifts, and thereby shuts valve L: the water in can C then passes out at the small opening in its bottom, and the weight F shuts sluice B, which stops as much water in the reservoir as the streams below have increased. When the water rises in the rivulet so as to flow out at aperture 5, it rises also in the tubes till it lift float X, which shuts another sluice. When the rivulet rises till the water flows out at aperture 6, it raises float Y, and shuts the third or last sluice, the flood being now supposed so great, that the streams below the reservoir are sufficient for the supply at Z. When the streams begin to fall, the rivulet at GH will also fall, and when the water ceases to flow into aperture 6, the water falls so far in the tubes as to let down float Y, and open one sluice; when it ceases to flow out at aperture 5, the float X falls, and a second sluice opens: when it ceases to flow out at aperture 4, the third sluice opens, which, with the other two, passes all the water that the rivulet is then bringing into the reservoir. Should the rivulet continue to fall so as not to flow out at aperture 3, then the water ceases to flow along QR, and one sluice shuts; should it fall below aperture 2, the water also ceases to flow along NO, and a second sluice shuts; should the rivulet become quite dry, then the third or last sluice shuts. Any number of sluices may be used, as found necessary: and in this way the same quantity of water will always run in the rivulet at Z, as if no reservoir had been placed in the rivulet above; except during floods, when all the water not needed at Z, would be retained in that reservoir. Besides the immense quantity of water thus gained during floods, the expense of cutting an aqueduct round the

* The first can only is shown in the engraving, but the relative situations of the other cans with respect to the pipes P and S, may be easily understood.

reservoir is also saved, nor is any by-wash necessary, as the main sluice on the reservoir that regulates the height of the water in the basin A, acts also as a water-sluice when necessary. When it is necessary to supply any fixed quantity of water from the reservoir, we have only to make an aperture in the basin of the proper size, and, as the water there stands always at the same height, the supply will always be the same.

The single weather sluice, fig. 11. One of the applications of this apparatus is, to give, at all times, an equal supply of water to any work, situated like Z, in the last case, where the reservoir is at a great distance from the work, and where it might be inconvenient or expensive to lay a pipe between them as in fig. 4. The description of the last figure applies also to this, only when the can C is filled with water, it shuts sluice BC, instead of opening it as in that figure. In very dry weather, when all the streams between the reservoir and the work are dried up, then it requires all the sluices at the reservoir to be open, to give the necessary supply to the works, but when the streams begin to flow a little, one sluice at the reservoir shuts, by the water flowing through aperture 1 into can C; when they increase still further, the water flows out at aperture 2, and along pipe NO, and shuts a second sluice; should they still increase till the water flow out at aperture 3, the third or last sluice shuts, the streams of themselves being now equal to the supply required. As the streams again fall off, the sluices will open, one after another, so as to keep the supply of water at the work always equal. It is necessary, in this case, to have a small reservoir near the work, to contain the water that flows down at night, or when the work is standing; and then this apparatus will be a complete substitute for the last apparatus, fig. 10. The purpose, however, for which this apparatus was invented was different. Having occasion to cut an aqueduct round the bases of some hills, to collect water, and convey it to a reservoir at a considerable distance, I found that to make the aqueduct so large as to convey all the water during floods would be too expensive; it therefore occurred to me, that if a part of the water could be detained during floods, and brought away gradually afterwards, a much smaller (and of course much less expensive) aqueduct would answer the purpose; I therefore made a small reservoir at a convenient place, and contrived this sluice to shut during floods, and to open as they decreased; and this answered the purpose intended completely, and was the origin of all the weather-sluices.

SLUSS, SLUDGE, or *Sluck*, a soft miry substance, serviceable in manuring land.

SMACK, a small vessel commonly rigged as a cutter, and used in the coasting and fishing trade, or as a tender in the king's service.

SMALL-POX, a highly infectious and formidable eruptive fever, which occurs in general but once to the same person. It is distinguished by the appearance of pustules on the third or fourth day of the fever. The face is sometimes dreadfully disfigured with the variolous corrosion. It is supposed to have existed in China and Hindostan several centuries before it was introduced into Europe. About the year 572 of the Christian era, it appeared at Mecca. From this place it was conveyed to Alexandria, and in the eighth century it was spread over France, Spain, and Italy, by the Saracens, in their progressive expeditions into the regions of the west.

SMALT, the last produce of cobalt, a kind of mineral matter, prepared and purified abroad, and brought hither sometimes in blue powder, and at other times in lumps. It is chiefly used with starch, and is generally known by the name of powder blue.

SMARTWEED, a troublesome weed, generally found in arable lands, and more commonly called arsesmart. Its juices have been known to remove warts, by frequently rubbing them with its green leaves a little bruised.

SMELL, SENSE OF. The sense of smell is very nearly allied to that of taste, and indeed many of those pleasurable sensations which are usually referred to the taste, as being received during the act of eating and swallowing, really belong to the smell. The organ of smell is a membrane or skin overspread with nerves, which line the internal cavity of the nostrils, and the surface and cavities of the bones which join the nostrils. This is affected both by the odorous particles which proceed from external substances through the nose, and by those that come from

the substances which are eaten: for there is a communication between the nose and the back part of the mouth. The disagreeable sensations occasioned by smell assist us in the proper choice of food, and prompt us to avoid such noxious vapours as may render the air injurious to health or life. It appears also, that offensive odours in various circumstances, contribute to generate the sense of shame, decency, &c. The pleasures of smell have a direct connexion with those of taste; and in several instances, such is their mutual union and co-operation, that the association appears almost inseparable. The fragrance which arises from the various productions of nature, adds new charms to her landscapes; and the pleasing sensations which enhance our mental enjoyments when inhaling the grateful incense, live in our recollections, when the representations of them are again brought before us in poetry and painting.

SMEETING, in Metallurgy, the fusing or melting of the ores of metals, in order to separate the metalline part from the earthy, stony, and other parts.

SMITHERY, or SMITHING, a manual art by which an irregular lump of iron is wrought into any intended shape.

SMOCK, LADY'S, or *Bitter Cress*, *Cardamine Amara*, in Agriculture, a plant of the weed kind, found in coppices, and on the banks of rivers, which sheep are said sometimes to eat. Some think the common sort is useful in epilepsies.

SMOKE, a humid matter exhaled in form of vapour by the action of heat, either external or internal. It consists of palpable particles elevated by means of the rarefying heat, or by the force of the ascending current of air, from bodies exposed to heat. Sir Isaac Newton observes, that smoke ascends in chimneys by the impulse of the air in which it floats; for that air being rarefied by the fire underneath, hath its specific gravity diminished, and being thus determined to ascend, it carries up the smoke along with it. Smoke of fat unctuous wood, such as fir, beech, &c. makes what we call lamp black. Smoke arising from the combustion of vegetables, is a mixture of water, oil, volatile salts, and all the gaseous products which result from the combination of vital air with the several principles of the vegetable. In the Philosophical Transactions, we have the description of an engine invented by Mons. Dalesme, which consumes the smoke of all sorts of wood, leaving nothing to affect either the sight or smell. It consists of several iron hoops, four or five inches in diameter, which shut into one another, and is placed on a trivet, but its mode of operation we have not seen.

SMOKE SAIL, a small sail, hoisted against the fore-mast when the ship rides head to wind, to give the smoke of the galley an opportunity of rising, and to prevent its being blown aft on to the quarter deck.

SMUGGLING, in civil economy, the importing contraband goods, or the selling of such as the law has made excisable, without paying the legal impost. Several severe laws have been enacted against this species of traffic, but no measures hitherto adopted have been able wholly to suppress the illicit trade. The preventive service holds it under the most powerful restraints.

SMUT, a disease in corn which destroys entirely the germ and substance of the grain.

SNAIL. See **HELIX**.

SNAKE in Zoology, a genus of serpents, the characters of which are, that they have abdominal and subcaudal scales. Of the snake tribes the species are vastly numerous, some of which are inoffensive, while others are dangerous in the highest degree. Those that live in warm climates sometimes grow to an enormous size, and many instances of their strength have been recorded, which appear almost incredible. In these sultry regions, their poison is also more acute than in other portions of the globe, but in general the largest have not been found the most venomous. Perhaps, of none is the poison more virulent than that of the rattlesnake.

SNAKE, Sea, a strange kind of fish, of the eel kind, said to reside in the northern seas, and to have been seen on the coasts of Norway, and on the shores of North America. The size and length of these creatures seem to be almost incredible. Some accounts represent them from fifty to seventy feet long, and others have extended their length to six hundred feet. There can be little doubt that some of these statements have been

exaggerated, the calculations of length having been made in all cases without actual measurement. The evidences, however, in favour of such creatures actually existing, have of late been so numerous and convincing, that the fact seems to be placed beyond the reach of all reasonable suspicion.

SNAKE Root, *Serpentaria*, in Medicine, the root of a species of *aristolochia*. Prior to the discovery of America, only two kinds of *serpentaria* were known; but since that event, several others have been added, such as the Virginian, the Canadian, and the Brazilian. The snake-root of Virginia was esteemed by the Indians as a sovereign antidote against the bite of the rattlesnake. Some travellers assert, that the smell of this antidote drives the rattlesnake away, on which account the Indians, when travelling in dangerous places, tie a portion of snake-root to the end of their staff, to prevent being bitten. In a dried state it is imported into this country in bales, each containing from two to five hundred weight. The smell is aromatic, not unlike that of valerian; and the taste is warm, sharp, and bitter, somewhat resembling that of camphor. It is highly esteemed for various medical purposes.

SNAKE Stone, a species of shell, of a flattened spiral figure, containing many circumsolutions, exhibiting a distant resemblance to a snake coiled up, and in that state becoming petrified. These snake-stones, generally described as *ammonites*, are very numerous in various parts of the world, but the race of animals, of which these are the remains, is supposed long since to have become extinct.

SNAKE Weed, in Agriculture, a common grass, frequently found by the sides of roads, which, if cultivated, would produce seeds answering the same purposes as those of buck-wheat. It is annual, or at most biennial, in its growth.

SNAKE Wood, in the *Materia Medica*, is the wood or root of the tree which affords the *nux vomica*. It is brought from the East Indies under the name of *lignum colubrinum*, in pieces about the thickness of a man's arm, covered with a rusty-coloured bark, and is internally of a yellow colour, with whitish streaks. When rasped, this wood yields an agreeable smell, though it is somewhat faint, and, on being tasted, the flavour is bitter.

SNAKING, is the winding small ropes spirally round a large one, the former lying in the intervals between the strands of the latter, and is frequently termed **WORMING**, which article see.

SNAPDRAGON, in Botany, see *ANTIRRHINUM*. The smaller sort of snapdragon is a troublesome weed in corn fields.

SNATCHBLOCK, a block having an opening in one of its sides, wherein to fix the bight of a rope occasionally. This is by some termed a rouse-about block.

SNEEZING, in Medicine, *sternutatio*, a violent convulsive motion of the muscles of respiration, which is preceded by a deep inspiration that fills the lungs, and then forces the air violently through the nose, while the under jaw is at the same moment closed. The effort shakes the head, and the whole body. This convulsive sensation is always excited by some irritation affecting the inner membrane of the nose; the air, therefore, which in coughing is expelled through the mouth, is vehemently driven through the nose, for the purpose of expelling that irritation.

SNIPE See *SCOLOPAX*.

SOAL-FISH. See *PLEURONECTES*.

SNORING, in Medicine, a sound produced by sleeping persons, in particular positions, apparently occasioned by the vibrations of the palate, in a state of relaxation, when the respiration is performed by breathing through the mouth and nose at the same time.

SNOW, a well-known substance, formed by the freezing of the vapours in the atmosphere. It differs from hail and hoarfrost, in being as it were crystallized, which they are not. This appears on examining a flake of snow by a magnifying glass; when the whole of it will appear to be composed of fine shining spicula, diverging like rays from a centre. As the flakes fall down through the atmosphere, they are continually joined by more of these radiated spicula, and thus increase in bulk like the drops of rain, or hailstones.

The whiteness of snow is owing to the small particles into which it is divided: for ice when pounded will become equally white. According to Beccaria, clouds of snow differ in nothing

from clouds of rain but in the circumstance of cold that freezes them. Were we to judge from appearances only, we might imagine that so far from being useful to the earth, the cold humidity of snow would be detrimental to vegetation. But the experience of all ages asserts the contrary. Snow, particularly in those northern regions where the ground is covered with it for several months, is of service to the earth, by guarding the corn or other vegetables from the intenser cold of the air, and especially from the cold piercing winds. It has been a vulgar opinion, very generally received, that snow fertilizes the land on which it falls, more than rain, in consequence of the nitrous salts which it is supposed to acquire by freezing. But it appears from the experiments of Margraaf in the year 1731, that the chemical difference between rain and snow water is exceedingly small. — Different vegetables are able to preserve life under different degrees of cold, but all of them perish when the cold which reaches their roots is extreme. Providence has, therefore, in the coldest climates, provided a covering of snow for the roots of vegetables, by which they are protected from the influence of the atmospherical cold. The snow keeps in the internal heat of the earth which surrounds the roots of vegetables, and defends them from the cold of the atmosphere.

SNOW, a vessel equipped with two masts, resembling the main and fore masts of a ship, and a third small mast just abaft the main-mast, carrying a sail nearly similar to a ship's mizzen; the foot of this mast is fixed in a block of wood, or kind of step, upon the deck, and the head is attached to the after-part of the main-top. The sail is called a try-sail, and hence the mast is termed a try-sail mast. When sloops of war are rigged as snows, they are furnished with a strong rope called a horse, instead of the try-sail mast, the fore part of the sail being attached by rings to it. This is generally the largest of all two-masted vessels employed by Europeans, and is reckoned the most convenient for navigation.

SNOW Bird, in Ornithology, a bird that appears in Scotland in severe weather, and deep snows. It is sometimes called snow-flakes, and occasionally breeds in the Highlands, on the summits of the highest hills, but the greater part emigrate from the extreme north, and their appearance indicates a rigorous season.

SNOW Drop. See *GALANTHUS*.

SNOW Grotto, an excavation made by the waters on the side of Mount Etna, by making their way under the layers of lava, and by carrying away the bed of puzzolana below them. This place is used for a magazine of snow; for in Sicily at Naples, and particularly at Malta, they are obliged, for want of ice, to make use of snow for cooling their wine, sherbet, and other liquors, and for making sweetmeats. See *RED SNOW*.

SNOW Plough, a contrivance for the purpose of clearing the roads of snow. It has been long used in Sweden, and has of late years been introduced into this country. It consists of boards brought to a point in the front, which enters the snow, and spreads behind to any given width which may be required. In this manner it is driven forward through the snow by horses, and the snow is thrown off on each side somewhat like furrows by the plough used in agriculture.

SNOW Stone, in Natural History, a beautiful stone found in some parts of America. It is richly variegated, and when polished exhibits an appearance resembling snow falling in all its whiteness upon a jetty surface.

SNUFF, a preparation of tobacco, made by reducing it into a powder, fit to be taken in at the nose, to clear the head of pituita. Many other ingredients are mixed with the tobacco, to give the snuff a more agreeable scent. The sorts already in use are too numerous to be named, and every month furnishes new combinations, possessing virtues till then unknown.

SOAP, in domestic economy, a composition of caustic alkali, salt, and oil, or other grease. The earths, and the other metallic oxides, also combine with fat and oils, forming neutral compounds. The former have been called earthy, and the latter metallic soaps. Soaps in common use are made with the fixed alkalis, combined with different kinds of fat and oil. These are divided into two principal varieties, hard and soft, which, in their being manufactured, undergo distinct processes. There are few compounds in which the chemical art appears to greater advantage in common estimation, than in the formation of soap.

Soap refuse, and soap suds, and most kinds of soapy mixture, have been found to be highly valuable as manure, and great promoters of vegetation.

SOAP Stone, a species of steatite. The name is derived from its colour, and from the peculiar unctuous sensation which it imparts to the feeling, which resembles that of white soap. It is sometimes striped and mottled with veins and spots of a dull purple. The only place in England where this stone is found, is at the Lizard, in Cornwall, connected with veins of serpentine, to which rock it seems nearly allied. It is much used in china manufactures.

SOAP Berry Tree. The berries of this tree are about the size of a musket bullet, and are winged with leaves. The skin and pulp are used as soap without any mixture whatever, and, in the cleansing of linen, they are a valuable and cheap substitute; but being of an acid nature, the finer articles of dress rot much sooner than under common soap. These berries are much used by the negroes. They are also said to have many medicinal virtues.

SOAPER'S WASTE. See SOAP.

SOAPY ROCK. See SOAP Stone.

SOCAGE, an ancient tenure, by which lands were held on condition of ploughing the lord's lands, and doing the other operations of husbandry, at their own charges.

SOCUS, in Antiquity, a kind of high shoe reaching above the ankle, worn by comedians, as the cothurnus was by tragedians.

SOCIETY, an assemblage or union of several persons in the same place, for their mutual assistance, security, interest, or entertainment. For the origin of civilized society, various causes have been assigned. To investigate the numerous theories that have been presented to the public on this interesting topic, would be an almost endless task. It would be scarcely less difficult to enumerate and characterize the various societies that have sprung up in civilized states.

SOCINIANS, in Church History, a sect of Christians so called from their founder Faustus Socinus, a native of Sienna, in Italy: they ascribe proper divinity to the Father only.

SOCK, in Agriculture, the share of a plough, or that part which opens the land.

SOCLE, or **ZOCLE**, in Architecture, a flat square member under the bases of pedestals, statues, vases, &c. which it serves as a foot or stand.

SOCO, in Ornithology, a Brazilian bird of the heron kind, remarkable for the length of its neck, and its variegated colours.

SOD, in Agriculture, a portion of turf or sward, cut or dug up. It also signifies the soil or earth. The square pieces of surface turf and earth, that are cut up in forming embankments and earth fences, are likewise termed soda.

SODA. This is found to be compounded of oxygen and a metallic basis called sodium; but as it is found thus combined, and as it is only in this state of combination that it is of the smallest importance, it deserves to be specially noticed. It was formerly called mineral alkali, as it is found in mineral seams and crusts; also in very great abundance in certain lakes near Alexandria in Egypt, in the dry season, being brought thither by the water which enters from the neighbouring country during the overflow of the Nile, and precipitated by the evaporation of the sun during the dry season. Barilla is the impure soda obtained by burning the *salsola* soda and other plants near the sea. Kelp is still more impure, containing only a small portion of pure alkali. It is obtained by burning sea-weed. For the purposes of commerce, soda is obtained from common salt, or muriate of soda.

SODALITE, in Mineralogy, is a stone that derives its name from the large portion of mineral alkali that enters into its composition. Its colour is a bluish green.

SODE-SHOOTS, in Botany, is a name given by some to the tree whose inspissated juice is the gum *tacamahacca* of the shops.

SODIUM, in Chemistry, is a simple body, and a metal. This was discovered by Sir Humphrey Davy in the year 1807. A few days prior to this event he had ascertained, that potass was a compound of a peculiar metal combined with oxygen; and he now found, that soda consisted of a metallic substance combined with oxygen. He first produced it by exposing soda to the action of the galvanic battery. It is now produced by

101-2.

fusing soda or muriate of soda with potassium. The potassium combines with the oxygen in the soda, and with the chlorine in the salt, leaving pure sodium. The metal is white, resembling silver, and having the same metallic lustre.

SOFA, in the East, is a kind of alcove raised about six inches above the floor of the apartment in which it appears. With princes it is a place of state, where visitors of distinction are received. When this ceremony is omitted, it is considered as a mark of disrespect. Sofa, with us, is a piece of furniture that may be ranked among the refinements and luxuries of civilized life. It serves either as a seat or couch, on which the occupier may sit or stretch himself at ease. The frame is of timber, and extends about six feet in length, and is sufficiently wide to render the seat comfortable. Sofas are covered with cotton, hair cloth, damask, or more costly articles, and generally stuffed with horse hair, and furnished with moveable cushions; and sometimes with mattresses formed of the same materials. The sofa has been immortalized by the poet Cowper in his "Task."

SOFFITA, in Architecture, any timber ceiling, formed of cross beams, or flying corniches, the square compartments or pannels of which are enriched with sculpture, painting, or gilding.

SOFT CHALK, a sort of fossil marl, which readily becomes blended with common vegetable mould, and therefore forms an excellent manure. It is chiefly valuable in lands that are stiff and unyielding.

SOIL, in Agriculture, is a general name applied to the surface of all sorts of land which will support vegetation. It is also more particularly applied to the fine powdery materials which have been gradually formed by time, from the various earthy and other bodies in nature, being ground down and incorporated with each other in divers states and proportions. It is therefore obvious that there must be great diversities of soil in different districts. The stratum which lies next below, is generally denominated the subsoil. Professor Davy, in an excellent paper on the analysis of soils, observes, that the substances which are found in soils are certain mixtures or combinations of some of the primitive earths, animal and vegetable matter in a decomposing state, certain saline compounds, and the oxide of iron.

SOILING, in Agriculture, the practice of supporting animals of various kinds, in the summer season, with green food of different sorts cut daily, and given to them in racks, in the houses, stalls, or yards, instead of sending them to the fields.

SOLANUM, in Botany, an ample genus, comprising various kinds of nightshade and other deadly plants.

SOLDER, **SODDER**, or **SODER**, a metallic or mineral composition used in soldering or joining other metals. Solders are made of gold, silver, copper, tin, bismuth, and lead, usually observing, that in the composition there shall be some of the metal that is to be soldered mixed with some higher and finer metals.

SOLDERING, the joining and fastening together of two pieces of the same metal, or two different metals, by the fusion and application of some metallic composition, on the extremities of metals to be joined.

SOLDIER, a military man, who voluntarily enlists to serve a prince or state for pay. The term includes officers of all ranks, as well as privates. The volunteer serves of his own accord without pay; the vassal is compelled to serve at his own expense; while the soldier, though a volunteer when he enters, is remunerated for his services, but is no longer free.

SOLE or **A GUN PORT**, is the lower part of it, and is more properly called the port sill.

SOLE of the Rudder, a piece of timber attached to the lower part of it, to render it nearly level with the false keel.

SOLECISM, in Grammar, a false manner of speaking, contrary the use of language and the use of grammar, either in respect of declension, conjugation, or syntax.

SOLEN, **RAZOR SHEATH**, or *knife-handle shell*, a genus belonging to the class of vermes, and order of testacea. The animal is an asceidia. The shell is a bivalve, oblong, and opening at both sides; the hinge has a tooth shaped like an awl, bent back, often double, not inserted into the opposite shell; the rim at the sides somewhat worn away, and has a horny cartilaginous hinge.

SOLICITOR, a person employed to take care of and manage suits depending in the courts of equity.

SOLID. Geometricians define a solid to be the third species of magnitude, or that which has three dimensions, viz. length, breadth, and thickness or depth. Geometric solids are the regular figures cut in wood or crystal.

SOLIDITY, is that property of matter by which it excludes all other bodies from the place which itself possesses.

SOLO, in Music, a term used in pieces consisting of several parts, to mark those that are to perform alone.

SOLSTICE, in Astronomy, is the time when the sun is at the greatest distance from the equator, and is thus called, because he then appears to be stationary in the zodiac; which arises from the obliquity of our sphere. There are two solstices in the year, generally denominated the summer and the winter solstice. The former is on the 21st of June, when the sun is in the tropic of Cancer, and all the inhabitants of the northern hemisphere have their longest day: the latter is on the 21st of December, when the sun enters the first degree of Capricorn, and makes the shortest day to the above inhabitants. To all those who live on opposite sides of the equator, the longest and shortest days, and the summer and winter seasons, stand reversed.

SOLUTION, in Chemistry, denotes an intimate mixture or perfect union of solid bodies with fluids, so as seemingly to form one homogeneous liquor.

SOMATOLOGY, comprehends our knowledge of bodies, or external substances. The properties of bodies, says Leslie, are detected by the senses, either from immediate observation, or through the application of experiment, and the aid of instruments. The more obvious properties are revealed to us merely by touch or sight; but the penetration of the telescope has enabled us to survey vast systems of worlds, dispersed through the remotest heavens; while the opposite power of the microscope has brought within our view, from the very verge of existence, a miniature creation of organized beings. Again, the most careless observer can hardly have omitted to perceive that the air is a compressible fluid, while it requires a very delicate experiment to discover the same property in water. The properties of body are either essential and permanent, or they are contingent, and susceptible of change or variation. Body is essentially, 1. extended; 2. figured; 3. impenetrable; 4. divisible; 5. porous; 6. contractile, or distensible.

SOMMITE, a mineral which is found in small crystals in the lava on the sides of mount Somma, which is a part of Vesuvius.

SOMNAMBULISM, sometimes called Noctambulism, or Sleepwalking. In this singular condition of the body, a person performs many voluntary actions, implying a certain degree of perception of the presence of external objects, but without any consciousness while the actions are performed, and without any recollection of them when consciousness returns. Of this very remarkable phenomenon many very singular accounts have been recorded, but the physical causes of sleepwalking remain yet in a great measure to be explored. Dugald Stewart, in his *Elements of the Philosophy of the Human Mind*, has the following observations in reference to Somnambulism: "There are many cases in which sleep seems to be partial; that is, when the mind loses its influence over some powers, and retains it over others. In the case of Somnambulism, it retains its power over the limbs, but it possesses no influence over its own thoughts, and scarcely any over the body, excepting those particular members of it which are employed in walking." Some, indeed, have doubted whether the state in which these persons are, who thus walk and act, can justly be denominated sleep. Dr. Cleghorn has pointed out several particulars in which this condition differs from sleep; and Dr. Darwin, in his *Zoonomia*, considers it as belonging to *reverie*, or as approximating to epilepsy, or catalepsy, rather than to real sleep. It must, however, be acknowledged, that these are but mere opinions and theories, totally unsupported by anything conclusive, and nearly all we know with certainty is, that the facts connected with Somnambulism are too obvious to be denied, while their causes have hitherto in a great degree eluded all research.

SONATA, in Music, a piece or composition intended to be performed by instruments only.

SONCHUS, in Botany, the *Sow Thistle*, so called because it is a plant of which swine are remarkably fond.

SONG, in Poetry, a little composition, consisting of easy and natural verses set to a tune in order to be sung.

SONG of Birds, has been defined to be a succession of three or more different notes, which are continued without interruption, during the same interval, with a musical bar of four crotchets in an adagio movement, or whilst a pendulum swings four seconds.

SONNA, a book containing Mahometan traditions, which all true Mussulmen are required to believe, though they be not included in the Koran, to which the Sonna is considered as a supplement.

SOOT, a substance deposited from the flame of burning vegetables.

SOPHI, or **SOFI**, a title of quality given to the emperor of Persia, which signifies wise, or sage, or philosopher.

SOPHISM, in Logic, &c. an argument which carries much of the appearance of truth, and yet leads to an error.

SORCERY, the crime of witchcraft, or divination, by the assistance of evil spirits.

SOREX, **SHREW**, a genus of quadrupeds of the order *feræ*. The generic character is, front teeth in the upper jaw two, long, bifid; in the lower, two or four, the intermediate ones shorter; canine teeth, several on each side; grinders cuspidated.

SORTES, in Antiquity, a method of deciding difficult cases by lots, dice, or the drawing of tickets.

SOUL, the spirit of man, which, in his present state, is adapted to the organization of his body, but which is capable of subsisting when it becomes disembodied. The word *soul* is understood in several other senses.

SOUND, on the coast of Norway in particular, is used for any opening of a river, or any gulf, or deep inlet of the sea, in the same sense as "deep" on the coast of Germany. In other parts it is more usually understood of a passage between the main land to which it is contiguous, and some island, which together form a strait or passage within such lands.

SOUND, or **HEARING**, sense of. The external air collects and modifies sounds; and by a long channel communicates them to the internal ear; this consists, in the first place, of what is called the drum of the ear, which is a small cavity, closed towards the opening of the ear by a delicate membrane. In the drum are three or four very small bones, furnished with muscles and joints. From the drum are several openings, one of which is to the mouth; the others communicate into the different recesses of the ear. One of these leads into the labyrinth, which consists first of a small irregular cavity, next of three semicircular canals, and lastly of a winding spiral canal, as unlike some sea shells. All these parts of the cavity are lined with a very delicate membrane, and filled with a watery fluid, which conveys to the portions of the nerve in contact with it, the vibrations received from the membrane which separates the labyrinth from the drum of the ear. The vibrations of the air act upon the drum, and thus set in motion the series of small bones in the cavity of the drum; these communicate the vibrations to the membrane which separates the drum from the labyrinth, and this (as before mentioned) produces vibrations in the watery fluid in the several parts of the labyrinth, and conveys to the nervous branches, which line the labyrinth, the vibrations originally produced on the drum. The mechanism is complicated, but what we understand must increase our reverential admiration of the skill which produced it. To illustrate the cause of sound, it is to be observed, 1st. That a motion is necessary in the sonorous body, for the production of sound. 2dly. That this motion first exists in the small and insensible parts of the sonorous bodies, and is excited in them by their mutual collision against each other, which produces the tremulous motion so observable in bodies that have a clear sound, as bells, musical chords, &c. 3dly. That this motion is communicated to, or produces a like motion in, the air, or such parts of it as are fit to produce and propagate it. Lastly, that this motion must be communicated to those parts that are the proper and immediate instruments of hearing. The sonorous body having made its impression on the contiguous air, that impression is propagated from one particle to another, according to the laws of pneumatics. Sound is conveyed through air with great rapidity. The motion of sound through the air is at the rate of about 13 miles in an hour.

SOUND, VELOCITY OF. By Dr. Olinthus Gregory. (Abstracted from a paper by Dr. G. in the Transactions of the Cambridge Philosophical Society for 1824.) The results of the experiments hitherto made to determine the velocity of sound present an extraordinary discrepancy; thus,

Feet per second.	Feet per second.
Mr. Roberts assigns a velocity of 1300	Cassini de Thiercy.... 1107
Mr. Boyle 1200	Meyer 1105
Mr. Walker and Duhamel 1338	Derham 1112
Mersenne 1474	Muller 1100
The Florence Academy. 1148	Picket 1130
	Arrago 1100-32

A series of experiments undertaken by Dr. Gregory produced the following results:

Velocity of sound.	Feet.	Velocity of sound.	Feet.
Fahr. therm. 27° . . .	1094.2	Fahr. therm. 60° . . .	1112
Ditto . 33 . . .	1099½	Ditto . 64 . . .	1114½
Ditto . 35 . . .	1102	Ditto . 66 . . .	1116
Ditto . 45 . . .	1107½	Ditto . 68 . . .	1118
Ditto . 50 . . .	1109½		1117

Of these results, some have been obtained in the day-time, others in the night; some when the sound has been transmitted over the surface of the earth, others when it has been transmitted over the surface of water; some are the result of direct sound, others of both direct and reflected sound; some from the report of cannons, others of muskets, others from the sound of bells. Were these the only experiments (says Dr. G.) on the subject that had ever been made, I should not regard them sufficiently extensive to justify me in deducing from them even an approximative rule. But as they have been made with great care, I may at least venture to present a rule, which, while it includes, with only slight discrepancies, all the preceding results, is simple enough to be easily recollected by practical men; and may, perhaps, be employed in our own climate. It is this:

At the temperature of freezing, 33°, the velocity of sound is 1100 feet per second.

For lower temperatures deduct } half a foot.
For higher temperatures add }

From the 1100 } for every degree of difference from 33° on to the 1100 }

Fahr. therm. the result will shew the velocity of sound, very nearly, at all such temperatures.

Thus, at the temperature of 50°, the velocity of sound is $1100 \times \frac{1}{4} (50-33) = 1108\frac{1}{4}$ feet.

At temperature 60°, it is $1100 + \frac{1}{4} (60-33) = 1113\frac{1}{4}$ feet; agreeing with the experimental result quite within the limits of a practical rule.

The above practical rule, so far as it may be entitled to confidence, may be useful, 1st, to the military man, in determining the distance of an enemy's camp, of a fortress, a battery, &c.; 2nd, to the sailor, in determining the distance of another ship, &c.; 3rd, to the landsurveyor, in ascertaining the length of base lines, &c. in conducting the survey of a lordship or county; 4th, to the philosophic observer, in appreciating the distances of thunder clouds during a storm. Yet in either of these applications, the rule must be regarded as approximative only; because few practical men can be expected to possess a time-measurer for less intervals than tenths of seconds, if, indeed, so small; and an error of a tenth of a second will occasion a mistake of from 32 to 40 yards in the estimate of the distance. Beyond this, however, the error need scarcely ever extend; because a mean of five or six careful experiments will usually give the interval to a degree of correctness far within the limits just specified. Indeed, an error of from 30 to 40 yards in a distance of three or four miles, will, on most occasions, where such approximative estimates are required, be of but small consequence. When the distance exceeds four miles, this method of approximating to it can only be employed under favourable circumstances of a very quiescent atmosphere, &c. Combining the results of experiments here recorded with those which have been formerly deduced by Derham and others, we may, I think, conclude unhesitatingly, 1st, That sound moves uniformly, at least, in a horizontal direction, or one that does not deviate

greatly from horizontality. 2nd, That the difference in intensity of a sound makes no appreciable difference in its velocity.* 3rd, Nor, consequently, does a difference in the instrument from which the sound is emitted. 4th, That wind greatly affects sound in point of intensity; and that it affects it also in point of velocity. 5th, That when the direction of the wind concurs with that of the sound, the sum of their separate velocities gives the apparent velocity of sound; when the direction of the wind opposes that of the sound, the difference of the separate velocities must be taken. 6th, That in the case of echoes, the velocity of the reflected sound is the same as that of the direct sound. 7th, That, therefore, distances may frequently be measured by means of echoes. 8th, That an augmentation of temperature occasions an augmentation of the velocity of sound, and vice versa.

SOUND, the French academicians made, in 1738, some experiments for measuring the velocity of sound: the Board of Longitude renewed these investigations in modern times, with all possible precision, when they found that the velocity of sound in the air, at the temperature of 65 degrees Fahrenheit, differs very little from 1044 feet per second.

SOUNDBOARD, in an Organ, is a reservoir into which the wind, drawn by the bellows, is conducted by a port vent, and hence distributed into the pipes placed over holes in its upper parts.

SOUND, in Geography, denotes in general any strait, or inlet, of the sea, between the two headlands.

SOUNDING, the operation of trying the depth of the water, and the quality of the ground, by means of a plummet sunk from a ship to the bottom. For sounding there are two plummets used, one of which is called the hand-lead, weighing about eight or nine pounds; and the other, the deep sea-lead, weighing from twenty-five to thirty pounds, and both are shaped like the frustum of a cone or pyramid. The former is used in shallow waters, and the latter at a great distance from the shore, particularly on approaching the land after a sea voyage. Accordingly the lines employed for this purpose are called the deep sea-lead, and the hand lead-line. The hand lead-line, which is generally twenty fathoms in length, is marked at every two or three fathoms, so that the depth of water may be ascertained either in the day or night. At the depth of two or three fathoms there are marks of black leather; at five fathoms there is a white rag; at seven a red rag; at ten black leather; at thirteen black leather; at fifteen a white rag; and at seventeen a red rag. Sounding with the hand lead, which is called heaving the lead by seamen, is generally performed by a man who stands in the main-chains to windward. Having the line all ready to run out without interruption, he holds it nearly at the distance of a fathom from the plummet, and having swung the latter backwards and forwards three or four times, in order to acquire the greater velocity, he swings it round his head, and thence as far forward as is necessary; so that by the lead's sinking while the ship advances, the line may be almost perpendicular when it reaches the bottom. The person sounding then proclaims the depth of the water, in a kind of song, resembling the cries of London hawkers. Thus if the mark of five fathoms is close to the surface of the water, he calls, "By the mark five," and as there is no mark at four, six, eight, &c. he estimates those numbers, and calls "By the dip four." If he judges it to be a quarter or a half more than any particular number, he calls, "And a quarter five," "And a half four," &c. If he perceives the depth to be three quarters more than a particular number, he calls it a quarter less than the next; then at four fathoms and three quarters, he calls "A quarter less five," &c. The deep-sea lead is marked with two knots at twenty fathoms, three at forty, four at fifty, and so on to the end. It is also marked with a single knot in the middle of each interval, as at twenty-five, thirty-five, forty-five fathoms, &c. To use this lead more effectually at sea, or in deep water on the sea-coast, it is usual previously to bring-to the ship in order to retard her course; the lead is then thrown as far as possible from the ship on the line of her drift, so that as it sinks the ship drives more perpen-

* The conservation of the notes in a tone, notwithstanding the difference in their intensity, being uninterrupted when heard at a distance, furnishes an elegant and decisive confirmation of this proposition.

dicularly over it. The pilot feeling the lead strike the bottom, readily discovers the depth of the water by the mark on the line nearest its surface.

JA SOUNDINGS, implies the being so near the land, as that a deep sea lead will attain the bottom, which is seldom practicable in the ocean.

SOUNDINGS, is also a name given to the specimen of the ground; a piece of tallow being stuck upon the base of the deep-sea lead, brings up distinguishing marks of the bottom, as sand, shells, ooze, &c. which adhere to it. The soundings, i. e. the depth of the water and the nature of the ground, are carefully marked in the log-book, as well to determine the distance of the place from the shore, as to correct the observations of former pilots.

SOUNDING Rod, a long piece of iron, marked with feet and inches, which being let down by a line in a groove by one of the pumps, indicates what water there is in the well, and consequently whether or not the ship leaks.

SOUP, a kind of pottage made of bread, broth, or the juice of flesh, with various other ingredients, usually served up at the beginning of a meal. *Portable Soup*, is a kind of cake, formed of concentrated broth, which being freed from all fat, and by long boiling having the most putrescent parts of the meat evaporated, is reduced to the consistence of glue, and will keep sound for many years. In long voyages this has been found to be a most valuable article of food.

SOUTH, one of the four cardinal points of the compass.

SOUTHING of the Moon, the time at which the moon passes the meridian of any particular place.

SOWING, in Agriculture, the act of scattering, or putting the seeds of grain, plants, &c. on or into the ground, in order to their producing crops.

SPACE, in Geometry, denotes the area of any figure, or that which fills the interval or distance between the lines that terminate it.

SPACE, in Mechanics, the line a moveable body, considered as a point, is conceived to describe by its motion.

SPADE, a well-known tool used in digging the soil; but its form is varied, according to the purposes to which it is applied.

SPADING, in Agriculture, is the taking off the sward or surface of grass land by means of the paring spade, with an intent to burn it.

SPAN, among Sailors, a small line or cord, the middle of which is usually attached to a stay, whence the two ends branch outwards to the right and left, having either a block or thimble attached to their extremities. It is used to confine some ropes which pass through the corresponding blocks or thimbles. To span in the rigging, is to draw the upper parts of the shrouds together by tackles, in order to seize on the catharping legs.

SPAN, a measure taken from the space between the thumb's end and the tip of the little finger, when both are stretched out. The span is estimated at three handbreadths, or nine inches.

SPANDRIL, in Architecture, the open space between the outward moulding of an arch, from its impost to the horizontal member or line which surrounds it.

SPANKER, another name for a ship's Driver, which see.

SPAR, in Mineralogy, a name given to those earths which break easily into rhomboidal, cubical, or laminated fragments with polished surfaces.

SPARE, an epithet applied to any part of a ship's equipage that lies in reserve, to supply the place of such as may be lost or rendered incapable of service; hence we say, spare tiller, spare top-masts, spare sails, &c.

SPARROW. See FRINGILLA.

SPARROW-HAWK. See FALCO.

SPARS, large round pieces of timber, fit for making top-masts, &c.

SPASM, in Medicine, a cramp: in its modern sense it signifies a continued and painful contraction of a muscle, or any portion of muscular fibres, and in this signification it stands opposed to convulsion.

SPATULA an instrument used by surgeons and apothecaries for spreading plasters, &c.

SPAVIN, a disease in horses, which being a swelling or stiffness usually in the ham, causes them to halt.

SPAWN, in Gardening, the progeny of plants, or other vegetables, which consists of such small offsets, suckers, and sprouts, as rise numerously from the root of the parent stock. These being taken off and planted, will readily take root, and become proper plants.

SPAWN, *Mushroom*, generated in old hot-beds, stable dung moderately dry, and the yards of livery stables, is the seed whence new crops of mushrooms spring.

SPAWN of Fish, the glutinous deposits, whence new generations, that continue the species, arise. Each kind has its own peculiar instinct, in reference to the manner, time, and place, of providing for its young; but the variations and singularities of the tribes belong to the natural history of the species.

SPAYING, an operation performed on the females of several kinds of animals, to prevent any further conception, and promote their fattening.

SPEAKER, of the House of Commons, a member of the house elected by a majority of the votes thereof, to act as chairman or president in putting questions, reading briefs or bills, keeping order, reprimanding the refractory, adjourning the house, &c. The first thing done by the commons, upon the first meeting of a parliament, is to choose a speaker, who is to be approved of by the king, and who, upon his admission, begs his majesty that the commons during their sitting may have free access to his majesty, freedom of speech in their own house, and security from arrests. The speaker is not allowed to persuade or dissuade in passing a bill, but only to make a short and plain narrative; nor to vote, unless the house be equally divided.

SPEAKING TRUMPET, a tube formed to collect the impulses of sound in speaking, and convey them forward to a distance. See ACOUSTICS.

SPEAR. See LANCE.

SPEARWORT, in Botany, the *Ranunculus Flammula*, generally deemed poisonous, but frequently used for medical purposes. The leaves, bruised to a kind of paste, and applied to the skin, will soon raise a blister. To sheep it proves very pernicious.

SPECIES, a term of relation. It comprises any number of individuals of the same common character, and yet it is less comprehensive than the term genus. That, however, which is a species in one relation, may become a genus in another. Thus, animal is a species as ranged under Body, but it is a genus in reference to Man, who now becomes a species of the more generic term Animal.

SPECIES, in Algebra, the characters or symbols made use of to represent quantities.

SPECIFIC, in Medicine, a remedy whose virtue and effect is peculiarly adapted to some certain disease, is adequate thereto, and exerts its whole force immediately thereon.

SPECIFIC GRAVITY, the relative weight of equal portions of different kinds of matter. For fluids and solids, the common standard of reference is pure distilled water at 62° Fahrenheit, which a cubic foot will weigh 1000 ounces. The specific gravity of water is called 1, or 1000.

SPECIFICATION, a statement of particulars given by a builder, an engineer, or artist, describing the dimensions and the peculiarities of the work he is about to undertake. Specifications must always be given when patents are to be obtained.

SPECTACLE, some remarkable object which arrests, or is designed to arrest, public attention. It is presumed to be always beheld with some passion or emotion of the mind.

SPECTACLES, an optical instrument, consisting of two lenses set in a frame, and fixed at a convenient distance before the eyes, to assist the sight. Spectacles are said to have been invented about the year 1290; but several individuals claim the honour of this discovery.

SPECTRUM, in Optics. When a ray of light is admitted through a small hole, and received on a white surface, it forms a luminous spot. If a dense transparent body be interposed, the light will be refracted in proportion to the density of the medium; but if a triangular glass prism be interposed, the light is not merely refracted, but it is divided into seven different rays. The ray of light no longer forms a luminous spot, but has assumed an oblong shape, terminating in semicircular arches, and exhibiting seven different colours. This image is called the spectrum, and, from being produced by the prism, the pris-

matic spectrum. These different coloured rays appearing in different places of the spectrum, shew that their refractive power is different. Those which are nearest the middle are the least refracted, and those which are the most distant, the greatest. The order of the seven rays of the spectrum is the following: red, orange, yellow, green, blue, indigo, violet. The red, which is at one end of the spectrum, is the least, and the violet, which is at the other end, is the most refracted. Sir Isaac Newton found, if the whole spectrum was divided into 360 parts, the number of the parts occupied by each of the colours to be the following:—red, 45 parts; orange, 27; yellow, 48; green, 60; blue, 60; indigo, 40; and violet, 80. These different coloured rays are not subject to further division. No change is effected upon any of them by being further refracted or reflected; and as they differ in refrangibility, so also do they differ in the power of inflection and reflection. The violet rays are found to be the most reflexible and inflexible, and the red the least.

SPECULARES, the name of a genus of fossils of the talc class.

SPECULUM, in Catoptrics, is a metallic reflector made use of in catadioptric telescopes, instead of the object-glass used in dioptric telescopes.

SPEECH, the act or art of expressing thought by articulate sounds, or signs invented for that purpose.

SPEEDWELL. See *VERONICA*.

SPELL, a kind of charm to drive away disease by hanging a piece of paper round the neck. It also signifies the extending an indefinite but strange influence over a person, which prevents the regular use of his natural powers. Spell is likewise used for a given period, during which one man or party relieves another in doing something that is laborious. In this sense it is common among sailors and miners.

SPERMACEI. This peculiar oily substance is found in the cranium of the physeter *monocephalus*, or spermaceti whale. It is obtained also from some other species.

SPHERE, in Mineralogy, a mineral composed of nearly equal parts of oxide of titanium, silice, and lime.

SPHERE, is a solid contained under one uniform round surface, such as would be formed by the revolution of a circle about a diameter thereof as an axis.

SPHERE, in Astronomy, that concave orb, or expanse, which invests our globe, and in which the heavenly bodies appear to be fixed and at equal distance from the eye.

SPHERICS, the doctrine of the sphere, particularly of the several circles described on its surface, with the method of projecting the same on a plane.

SPHEROID, a solid body approaching to the figure of a sphere, though not exactly round, but having one of its diameters longer than the other.

SPHINX, the *Hawk moth*, a genus of insects of the order *lepidoptera*. The generic character is, antennæ thickest in the middle, subprismatic, and attenuated at each extremity; wings deflected; flight strong, and commonly in the morning or evening.

SPHINX, in Sculpture, a figure representing a fabulous monster of that name. It is portrayed with the head and breasts of a woman, the wings of a bird, the claws of a lion, and the other parts of the body like those of a dog or lion.

SPHRAGIDE, or *Lemnian Earth*, in Mineralogy, a substance resembling fuller's earth, found in the island of Lemnos in the Mediterranean. It is in high repute in the East as an antidote against poison and the plague, and is dug only once a year, and that with great solemnity.

SPICA VIRGINIS, a star of the first magnitude in the constellation *Virgo*.

SPICE, any kind of aromatic drug that has hot and pungent qualities; such as pepper, nutmeg, ginger, cinnamon, and cloves. Some include under this term *senna*, *cassia*, *frankincense*, &c.

SPIDER, a creature too well known to require any particular description. Of this genus one hundred and twenty species have been enumerated; and of some, the natural history is exceedingly curious.

SPIELMANNIA, a genus of the *didynamia angiospermia* class and order.

SPIGELIA, *Wormgrass*, a genus of plants belonging to the

class of pentandria, and order of monogynia; and in the natural system arranged under the 47th order, *stellatæ*.

SPIKE, in Gunnery, to choke up the touch-hole with a nail, or something made on purpose, so as to render that piece of ordnance useless. Spike is also the nail or instrument with which the act is effected.

SPIKING up the Ordinance, a sea phrase used for fastening a quoin with spikes to the deck close to the breech of the carriage of great guns, that they may keep close and firm to the ship's sides, and not get loose when the ship rolls, and by that means endanger the breaking out of a butt-head of a plank.

SPINACIA, *SPINACH*, a genus of plants belonging to the class of dicercia, and to the order of pentandria; and in the natural system arranged under the 12th order, *holoracæ*.

SPINDLE, on Ship Board, a sort of iron pin tapering at the upper end to a point. It is fixed into the upper end of the top-gallant mast, so as to carry a vane, which turning thereon horizontally, shews the direction of the wind.

SPINDLE, is also the name of the lower end or foot of a capstan, which is shod with iron, and becomes the pivot or axis on which it turns in the saucer.

SPINE, the backbone in any animal, but, in reference to man, it is the articulated bony pillar at the back of the trunk, forming the foundation or basis of support and connexion to all the other parts of the frame.

SPINELL. See *RUBY*.

SPINET, or *SPINNET*, a musical instrument ranked in the second or third place among harmonious instruments.

SPINNING, the art of combining animal or vegetable fibres into threads or cords, by twisting them together. Wool, silk, cotton, flax, and hemp, are the matters most commonly employed for spinning into threads; and of these most of the vegetable fibres, except cotton, require to be wetted during the operation of spinning, to render them more supple; but cotton, wool, and silk, are spun in a dry state. The machines employed for spinning are of very different kinds, and adapted to the materials to be operated upon; but they have all a spindle, revolving with a rapid motion to twist the fibres which are attached to the end of it, and are supplied in a regular quantity, as fast as the twisting motion of the spindle will form them into a thread; and there is also some provision of a bobbin upon the spindle, to take up and retain the thread when made.

The most ancient mode of spinning is by the spindle and distaff, which, though exceedingly simple, was attended with much labour, and as the produce was small, the original method was laid aside. This simple but inconvenient method of spinning, however, becomes very efficient, when the spindle, instead of being spun upon the ground, is mounted in a proper frame and turned by a wheel and band: this forms a machine which is called the one-thread wheel, and is still used in the country for spinning wool; the spindle is made of iron, and placed horizontally, so that it can revolve freely; and the extremity of the spindle, to which the thread is applied, projects beyond the support. The wheel which turns it is placed at one side, the pivots of both being supported in upright pieces, rising up from a sort of stool. The spinner puts the wheel in rapid motion by its handle, and its weight is sufficient to continue the motion for some seconds; then walking backwards from the spindle, in the direction of its length, she supplies the fibres regularly, and the motion twists them into a thread; but when a convenient length is spun, the spinner steps on one side, and reaches out that arm which holds the end of the thread, so as to alter the direction of the thread, and bring it nearly perpendicular to the length of the spindle, which motion gathers or winds up the thread upon the middle of the projecting part of the spindle. This being done, she holds the thread in the direction of the spindle, so that it will receive twist, and retreats again to spin a fresh length of thread. For spinning wool, it is not wound round the distaff the same as flax, but the spinner holds a lock of it doubled over the fore-finger, and draws away the fibres from the middle part of a lock, to do which with regularity is the great art of spinning by hand.

A spinning machine more perfect than this is the one-thread flax-wheel, with spindle and flyer; it has the property of constantly drawing up the thread as fast as it is spun, instead of spinning a length and then winding it upon the spindle.

An improvement was made in the spinning wheel by Mr. Antis some years ago, which was an application of what Sir Richard Arkwright had before invented. The object is to obviate the necessity of stopping the wheel to remove the thread from one hook to another, in the manner just described. For this purpose the bobbin is made to move regularly backwards and forwards upon the spindle, a space equal to its length, so that every part will in succession be presented opposite the hook over which the thread passes, and thus receive the thread regularly upon the whole length of the bobbin. The invention has also another advantage over the old method, which always winds the thread in ridges upon the bobbin, and if the thread breaks in reeling the yarn, the whole bobbin may as well be thrown away, because the thread cannot easily be found again but this improved wheel always winds the threads across upon one another, by which means the end can never be lost.

It was not until the latter end of the last century, that spinning machines of greater powers were constructed; but all threads were spun by one of the machines which we have described; the first being used for cotton and wool, and the other with the bobbin and flyer, for flax; but for the very coarse threads, two spindles were applied to the latter machine, and the spinner having the wool wound round a band, tied it round her waist instead of winding it upon a distaff, and was thus able to draw out fibres with each hand, and supply two spindles. The first improvement of any importance in spinning, was that of the spinning jenny invented by Mr. Hargraves, as related in our article **WEAVING**. This was followed by the slubbing machine or billy, which by preparing the rovings for the jenny, a work which was previously performed by the hand, was deemed a considerable acquisition.

The inventions of Sir Richard Arkwright soon superseded these machines. His principal invention in the spinning was the introduction of the rollers to draw out or extend the fibres to their full length, which is by this means much more perfectly performed than by the fingers of the spinner. For the immediate twisting of the thread, he adopted the spindle, bobbin, and flyer of the old flax-wheel, placed in a vertical position, but added to it the important improvement of raising and lowering the bobbin, to distribute the thread regularly and equally upon all the length of it, the same which we have before described as being applied by Mr. Antis to the common spinning-wheel. The spinning jenny was again introduced, and rendered equal, and for some purposes superior, to the water frame, by Mr. Crompton, who combined with it the system of rollers, of Sir Richard Arkwright, and called the mule.

The great success attending the spinning of cotton by these machines, induced many persons to attempt the spinning of flax and wool by similar means. Short wool, for the manufacture of cloth, is spun by the billy and jenny; but flax and long wool for worsted require very different treatment from cotton and short wool, particularly the flax, owing to the great length of the fibres, and to their being of such irregular lengths; in consequence, when they are extended by the rollers on Arkwright's principle, some fibres will be broken, if the distances between the rollers is too small: and on the other hand, if the distance is too great, the fibres will not be properly extended. The latter, however, is the least evil of the two; and in consequence, the spinning frames for flax have the rollers, between which the extension or drawing out is effected, placed at a distance of from 14 to 18 inches between the first two pair of rollers, through which the flax passes; the next two pair, six or eight inches; after which it is passed between the third pair of rollers at a distance of five or six inches, and then delivered to the spindles, which are similar to those of the water-frame, but placed in an inclined position. The rollers are made in a very different way from those for cotton, being only narrow wheels just wide enough to receive the fibres of flax between them; and the fibres are prevented from getting out sideways by small tin spouts, through which the flax passes, as the rollers draw it forwards. The reason of this is, that the flinty surface of the flax would soon wear a hollow part round a plain roller, which would then let the flax slip through; but the narrow wheel wears down equally over the whole breadth of its edge. The lower pair of these rollers, or wheels, revolves in a small trough of water, in the same manner as a grindstone, and thus keeps the flax constantly

wet, which is necessary, in order to soften the fibres, and make them spin into a firm and smooth thread.

Worsted is also spun in a frame resembling the water-frame of Arkwright, from which it only differs in the relative distances of the rollers, by which the drawing out or extending of the fibres is effected.

Messrs. Clarke and Bugby obtained a patent in 1806, for improvements in a machine for spinning hemp and flax, which is intended to be worked by hand labour, and to be at such a small expense, as to bring it within the reach of small manufacturers. The inventors state it to be constructed upon such safe and easy principles, that no length of experience is necessary to enable children to work it; and that it occupies so little space, that the machines may be placed in small rooms, out-buildings, and other cheap places. To effect the above purposes, it was necessary to get rid of the flyer fixed upon the spindle used in the old machinery for spinning hemp or flax, which additions require a power in proportion of five to one; and also to surmount the difficulty which arises from the want of elasticity in these substances, and which prevents them from being spun by stretching out, at the same time that the thread is twisted in the manner of the mule or jenny. For farther particulars see **COTTON**.

SPINNING Wheel, in Rope-making, for twelve spinners to spin yarn at the same time is about five feet in diameter, and is hung between two posts fixed in the ground: on its top is fixed a semicircular frame, called the head, which contains 12 whirls, that turn on iron spindles, with hooks to their front ends to hang the hemp on, and are worked by means of a leather band encircling the wheel and whirls. The whirls are made to run with a true motion when the head on the rising side of the band has a larger segment of a circle than the falling side; or, in other words, let the base part of the head be longer from the middle than the opposite or falling side, by which means the band will be kept equally tight over the whirls, and consequently the motion will be alike to all. Heads made in this manner have the wheels turned always the same way.

SPINSTER, in Law, an addition usually given to all unmarried women, from a viscount's daughter downward.

SPIRACULA, in Entomology, holes or pores on each side of every segment of the abdomen, through which insects breathe.

SPIRAL, in Architecture and Sculpture, implies a curve that ascends winding about a cone or spire, so that all the points thereof continually approach the axis.

SPIRAL, in Geometry, a curve line of the circular kind, which in its progress recedes from its centre.

SPIRALE, **PROPORTIONAL**, are such spiral lines as the rhumb lines on the terrestrial globe.

SPIRIT, in Physiology, the most subtle and volatile part or juice of the body, by means of which its various functions and operations have been supposed to be performed. For **Spirits** distilled, see **ARAC**, **BRANDY**, **RUM**, &c.

SPIRIT, in Theology, signifies any incorporeal being that possesses intelligence. In the highest sense, God is a spirit; angels, devils, and the souls of men, are spirits. The term is more emphatically applied to the Holy Ghost. On the nature, qualities, and peculiar properties of spirit, the disputations among divines and metaphysicians have been carried to an almost immeasurable length.

SPIRITUALIZATION, in Chemistry, the act of extracting spirits from natural bodies.

SPIRKETING, that range of planks which lies between the water-way and the lower edge of the gun-ports within side of a ship.

SPLICING, among Seamen, to join the two ends of a rope together, or to unite the end of a rope to any part thereof, by interweaving the strands in a regular manner. There are several methods of splicing, according to the services for which it is intended; all of which are distinguished by particular epithets.

The short splice, is used upon the cables, slings, block-ropes and in general all ropes which are not intended to run through blocks, or where the splice is not in danger of being loosened. It is made by untwisting the ends of two ropes, or the ends of one rope, and having placed each of the strands of one opposite, and in the interval between two strands of the other, by pen-

trating the latter with a fid or marline spike, parallel to the axis or length of the rope.

The long splice, occupies a greater extent of rope, but by the three joinings being fixed at a distance from each other, the increase of bulk is divided; hence it is much neater and smother than the short splice, and better adapted to run through the channel of a block, &c. for which use it is generally intended.

The eye-splice, forms a sort of eye or circle at the end of a rope, and is used for splicing in thimbles, bulls-eyes, &c. and sometimes on the end of block-strops. The strands are therefore untwisted, and their extremities thrust through the three strands in that part of the rope whereon the splice is to be formed, and thence passing over the surface of the second strand, they are again thrust through the third, which completes the operation. There are other names for splices made in a similar manner to the eye-splice, but for a different purpose, being chiefly used in lead-lines, log-lines, and fishing lines, where the short splice would be liable to separation, as being frequently loosened by the water. It is made by splicing the ends of two lines at a short distance from each other; and the extremities of each being interwoven into the bight of the other lines, becomes double in the extent of the splice.

SPLINTERS, the pieces of a ship's side, masts, decks, &c. which being knocked off by a shot, acquire great velocity, and frequently do more damage among the men than the shot itself.

SPLINTER-Netting, sinnet made into nets, and nailed upon the inner part of the ship's sides, to lessen the effect of the splinters.

SPOILS, whatever is taken from an enemy in war; it is frequently denominated booty.

SPONDEE, *SPONDEUS*, in ancient Poetry, a foot consisting of two long syllables as, *om-nes*.

SPONGIA, *Sponge*, in Natural History, a genus of animals belonging to the class of vermes and order of zoophyta. It is fixed, flexible, and very torpid, growing in a variety of forms, composed of reticulated fibres, or masses of small spines interwoven together, and clothed with a living gelatinous flesh, full of small mouths or holes on its surface, by which it sucks in and throws out the water.

SPONGIOSE, in Anatomy, an appellation given to several parts of the body.

SPONSORS. See *GODFATHERS*.

SPONTANEOUS COMBUSTION. Many vegetable substances, highly dried, and heaped together, will heat, scorch, and at last burst into a flame. Of those, the most remarkable is a mixture of the expressed oil of the farinaceous seeds, as rape or linseed oil, with almost any dry vegetable fibre, such as hemp, cotton, matting, &c. and still more so, if also united with lamp-black or any other carbonaceous substance. These mixtures, if kept for a time undisturbed in close bundles, and in a warm temperature, even in small quantities, will often heat and burn with a smothered fire for some hours; and if air be admitted freely, will then burst into flame. To this, without doubt, may be attributed several accidental conflagrations in storehouses, and places where quantities of these substances are kept.

SPONTOON, is a weapon much like a halberd, formerly used instead of a half-pike, by the officers of foot.

SPOONDRIFT, a sort of showery sprinkling of the seawater, swept from the surface of the waves in a tempest, and flying according to the direction of the wind.

SPOTS, in Astronomy, dark places observed on the discs of the sun, moon, or planets. These were first discovered by Galileo in the year 1610, soon after he had completed his telescope.

SPOUT, the name of a trunk for conveying water from off the tops of buildings.

Spout, Water, or Water Spout, in Natural History, is an extraordinary elevation of the water at sea, and is very dangerous to ships. Its first appearance is in the form of a deep cloud, the upper part of which is white, and the under black. From the lower part of this cloud hangs down a conical tube, its biggest end at the top, which is called the spout. Under this tube the sea appears in a state of boiling agitation; the water rises, and stands as a column or pillar, some yards above the common surface; and from its extremity it spreads around

in a kind of smoke. Many instances have occurred where the water has risen when no spout has been visible. Water-spouts generally appear in warm dry weather, and when the sea is calm. This phenomenon is supposed, by some, to be occasioned by electricity, while others ascribe it to the meeting of contrary winds. It is, however, admitted, that water-spouts frequently appear without any indications of an adequate cause.

SPRAT, a small fish well known in London and other markets. The usual length is about four or five inches, and the body deep. From its superficial appearance some have erroneously thought it to be a young herring. But a minute examination will prove the species to be distinct.

SPRAY, the sprinkling or foam of the sea, which is driven from the top of a wave in stormy weather. It differs from the spooondrift, as being only blown occasionally from the broken surface of a high wave; whereas the latter continues to fly horizontally along the sea without intermission during the excess of a tempest or hurricane. It is sometimes called *spry*.

SPRING, in Natural History, a fountain or source of water rising out of the ground.

SPRING, in Mechanics, denotes a thin piece of tempered steel, or other elastic substance; which being wound up, serves to put several machines in motion by its elasticity, or endeavour to unbend itself; such is the spring of a clock, watch, &c.

SPRING, among Sailors, implies a crack running transversely or obliquely through any part of the mast or yard, so as to render it unsafe to carry the usual quantity of sail thereon.

SPRING, is also a rope passed out of a ship's stern, and attached to a cable proceeding from her bow, when she lies at anchor. It is usually performed to bring the ship's broad side, or battery of cannon, to bear upon some distant object, as another ship, a fortress on the coast, &c. When a ship rides by anchors which are only attached to one end, she will move like a weather-cock, according to the direction of the wind or tide. Now, if a rope be extended to the other end to the same anchor, it is evident that by slackening one of these ropes, and keeping the other fast, her side will lie more or less obliquely to the wind or tide as occasion may require, so as to be opposed to any distant object to the right or left. For instance, if a ship ride with her head northerly, and is required to cannonade a fortress lying on the south or south-east, a hawser is run out of the stern, and being carried forward without her fid, is attached to the cable, at a competent distance ahead of the ship; the hawser is then tightened by the capstan or tackles, and the cable being slackened the ship immediately turns her side towards the object intended to be battered.

SPRING, is likewise a rope extending diagonally from the stern of one ship to the head of another which lies abreast of her at a short distance, and is performed to make one of the ships sheer off to a greater distance from the other. Springs of this kind are occasionally applied to a wharf or pier for the same purposes.

To Spring a Mast, Yard, &c. is to crack it transversely or obliquely.

SPRING TIDE, the periodical excess of the elevation and depression of the tide, which happens soon after the new and full moon.

SPRINGS. *On the different Properties of Metal and Wooden.*—The spring is not only a very useful auxiliary, but an indispensable requisite, in many pieces of mechanism. But, from the difficulty of getting springs to stand, as the workmen express it, to their temper, they are not so frequently applied to the purposes of mechanics as otherwise they might be. Great judgment and skill, as every one knows who is conversant with the subject, are required, to give to a metal spring its due degree of temper; for, if made too hard, it snaps; if not hard enough, it acts. Metal springs, however, frequently fail from another cause, which is very little understood; in consequence of which, the failure is usually attributed, though, as presently will be seen, unjustly, to the unskilfulness of the workman. It is a circumstance not commonly observed respecting a metal spring, that if it has not something to stop against, but is suffered to vibrate after performing the requisite action, it will, in a short space of time, if the action be frequently repeated, either break or set. Whence this property arises, is not at present the object of inquiry. It is mentioned, that, in cases which

will admit of it, this inconvenience may be guarded against. In those cases in which the vibration cannot conveniently be avoided, a wooden spring, which is not subject to the like inconvenience, is the best, and perhaps the only substitute. A wooden spring is, in the property alluded to, the reverse of a metal one: if stopped in its vibration, it soon sets or breaks; if permitted to vibrate, its temper or elasticity suffers not the smallest diminution. Some years ago, the Reverend Edmund Cartwright established a mill for a manufacturing purpose, (we believe, for weaving by power, which was first introduced by him, and for which he was afterwards rewarded by parliament.) In this mill he had occasion to apply springs, under the circumstances mentioned above; he at first attempted to make use of metal ones, but in vain, being never able to make them stand a single day's work. He tried every kind of steel, and employed many different workmen, but still without success. Merely as a temporary expedient, till such time as he could get a fresh supply of steel springs, he one day tried a wooden one, which, to his agreeable surprise, completely answered his purpose; and from that time, as may be concluded, he never used any other than wooden ones. The experiment was perfectly decisive: the springs were in daily action for four years successively, making, in a common way, from forty to fifty strokes in a minute, on an average. At the expiration of the four years, those springs which had escaped accidents were as elastic, and as strong, as when first put into action. The wood they were made of was red deal, clean grained, and perfectly free from knots. To many manufacturers who employ machinery for various purposes, in which springs, that must be suffered to vibrate, form a part, this information, which may to some appear trivial, will be found highly useful.

SPRINGES, a sort of noose made of horse-hair, and sometimes spread on the ground, supported by a twisted willow, to ensnare birds. Springes are, however, used in various other ways, being occasionally set in hedges, on the boughs of trees, and in other places to which birds resort.

SPRIT, a small boom or pole, which crosses the sail of a boat diagonally from the mast to the upper aftmost corner, which it is used to extend and elevate; the lower end of the sprit rests in a sort of wreath, called the snottor, which encircles the mast at that place. These kind of sails are accordingly called sprit-sails.

SPRIT Sail, is also a sail attached to a yard which hangs under the bowsprit. It is furnished with a large hole towards each of its four corners, to evacuate the water with which the cavity or belly of it is frequently filled by the surge of the sea, when the ship pitches.

SPRIT Sail Top-sail, a sail extended above the former by a yard which hangs under the jib-boom; the clues of this sail are hauled home to the sprit-sail yard arms, after which the sail is drawn out towards the extremity of the boom, as any other top-sail yard is hoisted upon its mast. Formerly, the sprit-sail top-sails were set on a mast which was erected perpendicularly on the end of the bowsprit, but this method has of late been justly rejected as inconvenient and dangerous to the bowsprit, although serviceable in light breezes.

SPRIT Sail Top-gallant Sail, is set upon the flying jib-boom, in the same manner that the sprit-sail top-sail is set upon the inner jib-boom: this sail is, however, very rarely used.

SPROUT, the common name of a young shoot, offset, or sucker, which is thrown out by the parent plant or tree.

SPRUCE-BEER, a cheap and wholesome liquor, which is thus made: Take of water sixteen gallons, and boil the half of it. Put the water thus boiled, while in full heat, to the cold part, which should be previously put into a barrel, or other vessel; then add sixteen pounds of treacle or molasses, with a few table-spoonfuls of the essence of spruce, stirring the whole well together; add half a pint of yeast, and keep it in a temperate situation, with the bung-hole open for two days, till the fermentation is abated. Then close it up, or bottle it off, and it will be fit for being drunk in a few days afterwards.

SPUNGE, an instrument used to clean the cannon after firing, and to extinguish any sparks that may remain behind. They are sometimes made of bristles resembling a round brush, but more generally of sheep-skin with the wool outwards, nailed upon a block of wood nearly as large as the caliber of the piece

The block is either fixed upon a long wooden staff, or upon a thick piece of rope, well stiffened by serving it with spun-yarn. This latter is much more convenient on board of ships, on account of its flexibility; and is generally furnished with a block at the upper end, to use as a rammer. To sponge a gun, is to clean it out with the sponge; and should be constantly repeated after every explosion.

SPUNGE, or **SPONGE**, a marine substance found adhering to rocks, shells, &c. under cover of the sea-water, or on the sides of rocks regularly visited by the tides. It was long disputed whether this production of nature belonged to the mineral, the vegetable, or the animal kingdom; but it is now ascertained to be of animal origin, being the fabric and habitation of some species of worm or polype.

SPUN-YARN, a small line or cord formed of two, three, or more rope-yarns, twisted together by a winch; the yarns are usually drawn out of the strands of old cables and knotted together. Spun-yarn is used for various purposes, as seizing and serving-ropes, weaving mats, &c.

SPUR, a piece of metal, consisting of two branches encompassing a horseman's heel, and a rowel, in form of a star, advancing out behind to prick the horse.

SPY, a person hired to watch the actions, motions, &c. of another, particularly of what passes in a camp. When a spy is discovered he is hanged immediately.

SQUACCO, a large bird of the heron kind, that is bold and fierce. Its head is adorned with a crest of black, white, and yellow; and its plumage is variegated throughout with the same tints.

SQUAD, in Military language, denotes a small number of horse or foot, collected for the purpose of exercise.

SQUAD, *Awkward*, consists of such recruits, and others, as cannot go regularly through their military evolutions. It is frequently used as a term of reproach to such officers and men as are deficient in their duty.

SQUADRON, in Military Affairs, denotes a body of horse, whose number of men is not fixed, but is usually from one to two hundred. Each squadron usually consists of three troops of fifty men each.—**SQUADRON**, in Naval Affairs, either implies a detachment of ships employed on any particular expedition, or one-third part of a naval armament.

SQUALL, a sudden and violent gust of wind, usually occasioned by the interruption and reverberation of the wind from high mountains. These are very frequent in the Mediterranean, particularly that part of it which is known by the name of the Levant, as produced by the repulsion and new direction which the wind meets with in its passage between the various islands of the Archipelago.

A *Black Squall*, one attended with a dark cloud, which occasions a diminution of the usual quantity of light. A *White Squall*, produces no such diminution. A *Thick Squall*, is accompanied with rain, sleet, &c.

SQUALUS, the *Shark*, in Natural History, a genus of fishes of the order cartilagines. These animals are never found in rivers or lakes, inhabiting only the sea, and carrying terror and destruction wherever they appear. They grow in some species to the weight of three or four thousand pounds. They occasionally emit a phosphoric illumination, visible by night. They produce their young alive, several at a birth, but every one enclosed in a transparent hornlike substance, lengthened at the extremity into a thread which attaches to fixed substances, such as rocks or weeds. Some appear to live on vegetables chiefly, but the greater number are rapacious of animal substances in the extreme. They seize, indeed, whatever they find, with the most violent avidity, following in the wakes of ships, for the sake of nearly every thing thrown from them, and are fatal to those mariners who slip from their hold on the rigging into the sea, in which case the sharks are seen to tear them to pieces, with all the violence of competition. They are in most instances solitary wanderers through the ocean, but in some species they are gregarious. They contain large quantities of oil, and their skin is convertible to several useful purposes.

SQUARE, among Sailors, is a term peculiarly appropriated to the yards and their sails, either implying that they are at right angles with the mast or keel, or that they are of greater extent than usual. Thus, when the yards hang at right angles

with the mast, they are said to be square by the lifts; when they hang perpendicular to the ship's length, they are called square by the braces; but when they lie in a direction perpendicular to the plane of the keel, they are square by the lifts and braces; or, in other words, they hang directly across the ship, and parallel to the horizon. The yards are said to be very square, when they are of extraordinary length, and the same epithet is applied to their sails with respect to their breadth.

SQUARE-rigged, is a vessel used in contradistinction to all vessels whose sails are extended by stays, lateen, or lug-sail yards, or by gaffs and booms, the usual situation of which is nearly in a plane with the keel.

SQUARE Sail, is any sail extended to a yard suspended by the middle, and hanging parallel to the horizon, as distinguished from other sails which are extended obliquely. *Square Sail*, is also the name of a sloop's or cutter's sail, which hauls out to the lower yard, called the square-sail yard. This sail is only used in fair winds, or to scud in a tempest. In the former case it is furnished with a large additional part called the bonnet, which is then attached to its bottom, and removed when it is necessary to scud.

SQUARE. See GEOMETRY.

SQUARE NUMBER, the product of a number multiplied into itself.

SQUARE, in the Military Art, a particular formation into which troops are thrown on critical occasions particularly to resist the charge of cavalry.

SQUARE SOLID, is a body of foot, where both ranks and files are equal. It was formerly held in great esteem; but when the prince of Nassau introduced the hollow square, this was soon neglected.

SQUARE, Hollow, is a body of foot drawn up, with an empty space in the centre, for the colours, drums, and baggage facing every way, to resist the charge of the horse.

SQUARE, Oblong, a square which is 'not at right angles, but represents the figure of an oblong, whose sides are unequal.

SQUARE, Perfect, a square whose sides are equal and at right angles.

SQUILL, or **SEA ONION**, in the *Materia Medica*. The roots, or rather the bulbs, of this species, are the parts that are used in medicine. There are two sorts, the white and the red, but the latter is generally preferred. Squills grow naturally on sea-shores, or in ditches to which salt water has access. From Spain and the Levant, large quantities are annually imported into England.

SQUINTING, an irregular position and motion of the eyes, in which their axes do not converge to the object looked at.

SQUIRREL, a small animal well known in England, and in most other warm or temperate climates, where woods abound. During the summer it provides for the contingencies of winter, by laying up a store of nuts and other fruits. Its tail is formed chiefly of bushy hair, and being nearly as large as its body, serves it in some measure instead of wings, when darting from one tree to another, or even descending to the ground. Of the English squirrel the flesh is said to be delicate, and of an excellent flavour.

STABLE, a building constructed for horses and other animals, being furnished with stalls, and proper contrivances to contain their food and necessary equipments.

STACK, a quantity of corn, hay, pease, pulse, straw, or stubble, regularly piled up and thatched, to protect it from the inclemencies of the weather. Various forms prevail in different districts, and the dimensions are regulated by local circumstances.

STADIUM, an ancient Greek long measure, about a furlong.

STAFF, among Seamen, a light pole erected in different parts of a ship, whereon to hoist and display the colours. The *Ensign Staff*, is reared immediately over the stern, to display the ensign. The *Jack Staff* is fixed at the end of the bowsprit, to extend the jack. A *Flag Staff*, is erected at each of the mast-ends, or formed by their upper ends to support the flag or pendant of the respective squadron or division to which the ship belongs.

STAG, the *Red Deer*, or *Hart*.

STAGE, among Ship-carpenters, is a machine composed of planks, let over the sides by ropes, whereon the people may stand when repairing, caulking, or paying the ship's sides,

wales, &c. A *Floating Stage*, is one which needs not the support of ropes, being sufficiently large and firm to bear upon the water.

STAGGERS, a disease in horses, nearly allied to apoplexy in human beings. It consists of a giddiness in the head, and is sometimes indicated by madness.

STAIRCASE, an ascent enclosed between two walls, or a balustrade, consisting of steps or stairs, with landing places and rails; serving to make a communication between the several stories of a house.

STALACTITÆ, or **STALACTAGNIA**, stony concretions resembling icicles, in *Natural History*; or crystalline spars formed into oblong, conical, round, or irregular bodies, composed of various crusts, and usually found hanging in form of icicles from the roofs of grottoes.

STALK, that part of a plant which rises immediately from the root, and supports the leaves, flowers, and fruits.

STAMINA, in the animal body, are defined to be those simple original parts, which existed first in the embryo.

STAMMERING, a hesitation in pronunciation, or interruption of speech, which seems generally to arise from fear, eagerness, or some violent passion. This should be checked as much as possible in its early stages, by slow and deliberate pronunciation; for once confirmed into a habit, it becomes inveterate.

STAMP DUTIES, a tax imposed upon all parchment and paper on which any legal proceedings are written; and also upon licenses for retailing wines; upon all almanacks, newspapers, advertisements, cards, dice, and pamphlets of a certain description.

STAMPS, in Metallurgy, large heads of iron fastened to timbers that are lifted by the revolution of a water wheel. These falling on the ore that is incorporated with refuse, beat the whole to powder, that the valuable parts may be separated from the useless, and preserved.

STANCHIONS, those pillars which being set up pillar-wise, support and strengthen the waste-trees, but are chiefly intended to support the weight of the artillery. They are used for various purposes.

STANCHIONS of the Nettings, are either slender bars of iron whose lower ends are fixed in iron sockets at proper distances, or square wooden pillars let into the upper part of the ship's side.

STANDARD, in Ship-building, is an inverted knee, placed upon the deck instead of beneath it, and having its vertical branch pointed upwards from that which lies horizontally.

Royal STANDARD, a flag in which the imperial ensigns of England, Scotland, and Ireland, are quartered, together with the armorial bearings of Hanover. It is never hoisted unless when the king is on board, at which time it is displayed at the main-top-gallant-mast head.

STANDARD, in Commerce, the original of a weight, measure, or coin, committed to the keeping of a magistrate, or deposited in some public place, to regulate, adjust, and try the weights used by particular persons in traffic.

STANDARD, in Military affairs, a measure by which men enlisted into his majesty's service have the regulated height ascertained.

STANDARD, in War, a sort of banner or flag, borne as a signal for the joining together of several troops belonging to the same body.

STANDING, in the Sea Language. Standing part of the sheet, is that part of it which is made fast to a ring at the ship's quarter. Standing part of a tackle, is the end of the rope where the block is fastened. Standing ropes, are those which do not run in any block, but are set taut or let slack as occasion serves, as the sheet-stays, back-stays, or the like.

STANNARIES, certain laws to which those who dig and purify tin in the counties of Cornwall and Devonshire are subject. There are four stannary courts for each of the above counties, to which appeals are made by the tinners, and in which justice is administered by the lord and vice-wardens, who preside. An appeal lies from these courts to the privy council of the prince of Wales, as duke of Cornwall, and thence, finally, to the king himself.

STANZA, in Poetry, a certain stated number of grave
11 L

verses, containing a perfect sense, and terminated with some significant pause.

STAPLE, primarily signifies a public place or market, whither merchants, &c. are obliged to bring their goods to be bought by the people, as the Greve, or the places along the Seine, for sale of wines and corn at Paris, whither the merchants of other parts are obliged to bring those commodities. Formerly the merchants of England were obliged to carry their wool, cloth, lead, and other like staple commodities of this realm, in order to utter the same by wholesale; and these staples were appointed to be constantly kept at York, Lincoln, Newcastle upon Tyne, Norwich, Westminster, Canterbury, Chichester, Winchester, Exeter, and Bristol; in each whereof a public mart was appointed to be kept, and each of them had a court of the mayor of the staple, for deciding differences, held according to the law-merchant, in a summary way. The staple commodities of this kingdom are said by some to be these, viz. wool, leather, wool-felts, lead, tin, butter, cheese, cloth, &c. but others allow only the first five to be staple commodities.

STAPLING or Wool, the art or process of adjusting the qualities and different properties of wool in the same fleece, selecting the fine from the coarse, and placing together the more valuable parts. This is frequently called sorting.

STAR, in Astronomy, a general name for all the heavenly bodies, which are dispersed through the whole heavens.

Stars, Falling, in Meteorology, meteors which dart through the sky in the form of a star.

STAR, in Pyrotechny, a composition of combustible matters, which being thrown aloft in the air, exhibits the appearance of a real star.

STAR-SKOT, a gelatinous substance frequently found in fields, and is the half-digested food of herons, sea-mews, and the like birds; for these birds when shot have been found to disgorge a substance of the same kind.

STARBOARD, the right side of a ship when the eye of a spectator is directed forward.

STARBOARD, is also an order to the helmsman to put the helm a little to the starboard side; and is used only when the ship is going large or free.

STARCH. If a quantity of wheat-flour be formed into a paste, and then put under a very small stream of water, stirring it continually, till the water runs off from it colourless, the flour by this process is divided into two distinct constituents. A tough substance of a dirty white colour, called gluten, remains in the hand; the water is at first milky, but soon deposits a white powder, which is known by the name of starch.

STARLING, in Ornithology, a bird about the size of the common blackbird. The whole plumage is a resplendent black, with changeable blue, purple, copper, tints of green, and small yellow spots. During winter they assemble in large flocks. Pennant says, they may be taught to speak; and Ray observes, that they imitate the human voice much better than the parrot.

STATE, an empire, kingdom, province, or extent of country, under the same government.

STATICE, in Botany, a name now applied to the common thrift, or sea gilliflower.

STATICS, that branch of mathematics which considers the motion of bodies arising from gravity.

STATION BILL, a list containing the appointed posts of the ship's company when navigating the ship.

STATIONARY, in Astronomy, the state of a planet when it seems to remain immoveable in the same point of the zodiac.

STATIONERS. This denomination of venders of books, paper, &c. is derived from the following circumstance. The traffic of books was anciently very inconsiderable, in so much that the book merchants of England, France, and Spain, and other countries, were distinguished by the appellation of Stationers, as having no shops, but only stalls and stands in the streets.

STATISTICS, a word lately introduced to express a view or survey of any kingdom, county, or parish.

STATUARY, a branch of sculpture, employed in the making of statues. In this art the ancients are thought to have excelled the moderns. Among the former, the name of Phidias stands pre-eminent; and among the latter, that of Michael Angelo.

STATUES, are figures representing living or deceased creatures, of whatever species, real or imaginary; and carved, cast, modelled, or moulded, in full relieve, inscribed on every part. Statues are formed with the chisel, of several materials, such as marble, stone, &c.: they are carved in wood, or cast in plaster of Paris, or other matter of the same nature; they are also cast in several metals, as lead, brass, silver, and gold.

STATURE, the height or pitch of a man, which is found admirably adapted to the circumstances of his existence.

STATUTE in its general sense, signifies a law, ordinance, decree, &c. Statute, in our laws and customs, more immediately signifies an act of parliament made by the three estates of the realm; and such statutes are either public, of which the courts at Westminster must take notice, without pleading them, or they are special and private, which last must be pleaded.

STATUTE Merchant, is a bond of record acknowledged before one of the clerks of the statute merchant, and lord mayor of the city of London, or two merchants of the said city for that purpose assigned, or before the mayor or warden of the town, or other discreet men, for that purpose assigned.

STATUTE Staple, is a bond of record acknowledged before the mayor of the staple, in the presence of all or one of the constables: but now statute staple, as well as statute merchant, are in great measure become obsolete.

STATUTES, or *Statute Sessions*, otherwise called *petit sessions*, is a meeting in every hundred of all the shires in England, whereto the constables and others, both holder and servants, repair for the debating of conferences between masters and servants, the rating of servants' wages, and bestowing such people in service as, being fit to serve, either refuse to seek or get masters.

STAUROLITE, in Mineralogy. This stone has been found at Andresberg in the Hartz. It is crystallized, and the form of its crystals has induced mineralogists to give it the name of cross-stone. Its crystals are two four-sided flattened prisms, terminated by four-sided pyramids, intersecting each other at right angles; the plane of intersection passing longitudinally through the prism. Sometimes these prisms occur solitary. Primitive form, an octahedron with isosceles triangular faces, the faces of the crystals striated longitudinally.

STAVE, in Music, the five horizontal and parallel lines on and between which the notes are placed.

STAY, a large strong rope, employed to support the mast on the fore part, by extending from its upper end towards the stem of the ship, as the shrouds are extended on each side. The *Fore Stay*, is that which reaches from the fore-mast head towards the bowsprit end. The *Main Stay*, is that which extends to the ship's stem. The *Mizzen Stay*, is that which is stretched to a collar on the main-mast immediately above the quarter-deck. The *Fore Top-Mast Stay*, is that which comes to the end of the bowsprit, a little beyond the fore-stay. The *Main-Top-Mast Stay*, is attached to the hounds of the fore-mast. The *Mizzen Top-Mast Stay*, is that which comes to the bounds of the main-mast. The *Fore-Top-Gallant Stay*, is that which comes to the outer end of the jib-boom. The *Main-Top-Gallant Stay*, is that which is extended to the head of the fore-top-mast. The *Mizzen-Top-Gallant Stay*, is that which is attached to the head of the main-mast. The *Royal Stays*, when used, are those which extend to the jib-boom end, or to the heads of the top, or top-gallant masts next before them. The whole of these stays are nearly in the direction of the upper edges of the several stay-sails which derive their names from them.

SPRING STAY, is a kind of assistant stay, extending in a direction nearly parallel to the principal stay, it is much thinner than the other, and is only used to the lower-masts and top-masts.

STAY-Sail, any sail extended upon a stay.

STAY-Sail-Stay, a rope used solely to extend and support a stay-sail, as the middle stay-sail.

STAY-Tackle, a large tackle, attached by means of a pendant to the main-stay. It is used to hoist heavy bodies, such as the boats, or butts of water, beer, &c. in or out of the ship, and out of the holds; for which purpose there are generally two, the one over the fore-hatchway, the other perpendicular to the main-hatchway; and they are accordingly distinguished by the epithets, main or fore stay-tackles, though both are upon the main-stay.

STEADY, at Sea, the command given to the helmsman in a fair wind, to steer the ship in the line on which she advances at that instant, without deviating from the right or left; to which the helmsman answers, "Steady," to shew his attention to the order.

STEALING, the fraudulent taking away another man's goods, with an intent to steal them against, or without, the will of him whose goods they are.

STEAM, water converted by heat into vapour.

STEAM-ENGINE, an engine originally contrived for raising water by means of the expansive force of the steam or vapour produced from water or other liquids in a state of ebullition.

General Principle of the Steam Engine.—The force of the steam-engine is derived from the property of water to expand itself in an amazing degree, when heated above the temperature at which it becomes changed into steam or vapour, which being an exceedingly elastic fluid, it can be retained within the close vessel or boiler to which the heat is applied, even when it has an expansive force sufficient to make it fill, if left at liberty, 20 or 30 times the space in which it is confined. In this state the steam will exert a proportionate force or pressure to burst open the sides of the vessel in which it is retained; which force may be applied either to expel or raise up water from any vessel into which the confined steam is admitted, or to give motion to a moveable piston, which is so accurately fitted to the interior capacity of such vessel, as not to permit the escape of the steam between them.

Another source of the power of the steam engine, is the facility with which steam of a great expansive force can be cooled by the application of cold water, and condensed into the small quantity of water from which it was originally produced. A partial vacuum can thus be made, in a very large vessel, in an instant, and even in the same vessel, which was, a moment before, filled with confined steam, exerting a great force to escape. The pressure of the atmosphere which tends to fill up this vacuum, can be made to produce the ascent of water into the vessel to any height less than twenty-four or twenty-five feet. Or the pressure of the atmosphere may be made to give motion to a piston, by admitting the atmospheric air to press upon one side of the piston, whilst there is a vacuum space formed by the condensation of the steam which filled the cylinder on the other.

Notwithstanding the great variety of different constructions of the steam-engine, they all derive their force from one of these two principles, or from the combination of the two; but before entering upon any description of the manner in which these forces are applied, it is necessary to have clear ideas of the nature of steam, and of the law by which it expands by heat, in order to form a precise judgment of what passes in the interior part of a steam-engine when it is at work. In the common acceptance of the word steam, it is that hot white vapour which we see every day rising in a cloud from a tea-kettle, or a boiling pot: but this is not exactly the state of the steam employed in an engine; it is there perfectly transparent, and is more or less hot than boiling water, according as it is retained under a lesser or greater degree of compressure. The ordinary pressure of the atmosphere, bearing upon the surface of the water, will retain it in a state of fluidity, until it is heated to what is generally called the boiling point, and is marked 212° in Fahrenheit's thermometer. If the heat is increased above that degree, and if the water is unconfined except by the pressure of the atmosphere, the water immediately assumes the aeriform state, and flies off in elastic vapour, which we call steam; but if the same water is relieved from the pressure of the atmosphere by enclosing it in a close vessel, and exhausting the air from it, a certain portion of steam or vapour will rise from the same at any temperature, even when it is as low as freezing; and if this vapour is conveyed off from the vessel as fast as it rises, the water, although cold, will boil, and such vapour will rise as fast as from the boiling kettle in the open air. If the vapour is retained in the vessel, it will only accumulate, until it has acquired a certain degree of elastic force to press upon the surface of the water, which will then cease to yield any more vapour, until the heat is farther increased, or that the vapour is drawn off to relieve the water from the pressure which confined and retained it in its fluid state. On the other

hand, water which is retained in a close vessel, under a greater degree of pressure than that occasioned by the pressure of the atmosphere, will not boil or rise in vapour, until it becomes heated to a higher temperature than 212°. It is even probable, that water might be compressed to that degree, that it would not boil until heated red-hot; but this would require such an enormous strength in the vessel which should contain the steam, that it is far beyond the practicability of an experiment. In this manner the reader is to bear in mind, that vapour or steam, when confined in close vessels, is always more or less elastic, in proportion to the degree of heat which is applied to it; or, in other words, that the temperature of the steam is an exact index of the elastic or expansive force with which it presses upon the surface of the water, and against the interior surface of the vessel which contains it.

The first notice which we have of the steam-engine, is in a small pamphlet by the Marquis of Worcester, written in 1665, and published during the reign of Charles II. in 1683, entitled, "A Century of the Names and Scantlings of the Marquis of Worcester's Inventions." In the sixty-eighth article of this Century of Inventions, the author thus speaks:—"An admirable and most forcible way to drive up water by fire! not by drawing or sucking it upwards, for that must be as the philosopher calleth it, *intra spheram activitatis*, which is but at such a distance. But this way hath no bounder, if the vessel be strong enough: for I have taken a piece of a whole cannon, whereof the end was burst, and filled it three-quarters full of water, stopping and screwing up the broken end, as also the touch-hole; and making a constant fire under it, within twenty-four hours it burst, and made a great crack; so that having a way to make my vessels, so that they are strengthened by the force within them, and the one to fill after the other, I have seen the water run like a constant fountain stream forty feet high; one vessel of water, rarefied by fire, driveth up forty of cold water. And a man that tends the work is but to turn two cocks, that one vessel of water being consumed, another begins to force and refill with cold water, and so successively; the fire being tended and kept constant, which the self-same person may likewise abundantly perform in the interim between the necessity of turning the said cocks."

However plain these hints may now appear, they were thought at the time when first published, to border so much on the marvellous and romantic, as to be scarcely worthy of notice; and finally, from being neglected, they became nearly forgotten. At length, after a lapse of about forty years, Capt. Thomas Savery, a commissioner of sick and wounded, obtained a patent in 1698, for "A new invention for raising water, and occasioning motion to all sorts of millwork, by the impellent force of fire." Of this contrivance, a small model was exhibited to the Royal Society, and in vol. xxi. of their Transactions, their approbation is recorded. The inventor afterwards published an account of his engine in a small book, entitled, "The Miner's Friend," accompanied with an engraving; which shews that this early effort of genius had made a bold advance toward perfection.

It appears from Captain Savery's description, that his engine not only derived its power from the expansive force of steam, like that of the Marquis, but also by the condensation of steam, the water being first raised by the pressure of the atmosphere, to a given height from the well into the engine, and then forced out of the engine up the remaining height, by the expansive force of steam. This action was performed alternately by two receivers, so that while the vacuum formed in one, was drawing up from the well, the pressure of the steam in the other was forcing up water into the reservoir. The power and utility of Savery's engine being every where acknowledged, many improvements were subsequently made by various engineers, in its appendages, arrangements, and the adjustments of its parts; but nothing of importance appeared, to mark an era in the history of the steam-engine, until about the year 1706, when Thomas Newcomen, ironmonger, and John Cawley, glazier, of Dartmouth, obtained a patent for a new invention; but so far was their principle of movement connected with that of Savery, that the latter was admitted to a participation in their patent.

The engine thus brought into use is sometimes called the atmospheric engine, and is commonly a forcing pump, having

its rod fixed to one end of a lever, which is worked by the weight of the atmosphere upon a piston at the other end, a temporary vacuum being made below it by suddenly condensing the steam that had been admitted into the cylinder in which this piston works, by a jet of cold water thrown into it. A partial vacuum being thus made, the weight of the atmosphere presses down the piston, and raises the other end of the straight lever, together with the water, from the well. Then immediately a hole is uncovered in the bottom of the cylinder, by which a fresh quantity of hot steam rushes in from a boiler of water below it, which proving a counterbalance for the atmosphere above the piston, the weight of the pump-rods, at the other end of the lever, carries that end down, and raises the piston of the steam-cylinder. The steam hole is then immediately shut, and a cock opened for injecting the cold water into the cylinder of steam, which condenses it to water again, and thus making a vacuum below the piston, the atmosphere again presses it down, and raises the pump-rods as before; and so on continually.

On this engine some considerable improvements were afterwards made by Mr. Smeaton, which though containing little that was new in principle, tended much to facilitate the progress of this mighty agent in the mechanic arts. The improvements made by Watt upon the engine of Newcomen and Cawley are first, that the elasticity of the steam itself is used as the active power in this engine; and secondly, that besides various other judicious arrangements for the economy of heat, he condenses the steam, not in the cylinder, but in a separate vessel.

In the cylinder or syringe, concerning which we have spoken, in mentioning the engine of Newcomen, let us suppose the upper part to be closed, and the piston rod to slide air tight through a collar of leathers. In this situation it is evident that the piston might be depressed by throwing the steam upon its upper surface, through an aperture at the superior end of the cylinder. But if we suppose the external air to have access to the lower surface of the piston, we shall find that steam no stronger in its elasticity than to equal the weight of the atmosphere would not move the piston at all; and consequently that this new engine would require much denser steam, and consume much more fuel, than the old engine. The remedy for this evil is to maintain a constant vacuum beneath the piston. If such a vacuum were originally produced by steam, it is certain that its permanency could not be depended on, unless the engine contained a provision for constantly keeping it up. Watt's contrivance in his simplest engine is as follows:—The steam is conveyed from the boiler to the upper part of the cylinder through a pipe, which also communicates occasionally with the lower part, and beyond that space with a vessel immersed in a trough of water; in which vessel the condensation is performed by an injected stream of cold water. This water is drawn off, not by an eduction pipe but by a pump, of which the stroke is sufficiently capacious to leave room for the elastic fluid, separated during the injection, to follow and be carried out with the injection water. Suppose now the piston to be at its greatest elevation, and the communication from the boiler to the upper as well as to the lower parts of the cylinder to be opened. The steam, under these circumstances, will pass into the whole internal part of the engine, and will drive the air downwards into the condenser, and thence through the valves of the air pump. In this situation, if the communication from the boiler to the lower part of the cylinder be stopped, and an injection be made into the condenser, a vacuum will be produced in that vessel, and the steam contained in the lower part of the cylinder and communication pipe will expand itself with wonderful rapidity towards the condenser, so that in a period of time too minute to be appreciated, the whole of the steam beneath the piston will be practically condensed. The steam which continues to act above the piston will immediately depress it into the vacuum beneath; at the same time that by connexion with the external apparatus, the piston of the air pump also descends in its barrel. When the stroke is nearly completed downwards, the requisite part of the apparatus shuts the communication with the boiler, opens that between the upper and lower parts of the cylinder and condensing vessel, and turns the injection-cock. At this very instant the piston loses its tendency to descend, because the steam presses equally on both surfaces, and continues its equality of pressure while the condensation

is performed. It therefore rises; the injection is stopped; and the air-pump making its stroke suffers the injection water and a considerable part of the elastic fluid to pass through its lower valve. The vacuum is thus kept up through the whole internal capacity of the engine. As soon as the piston has reached the upper part of the cylinder, the communication to the under part of the cylinder is stopped, and that with the boiler opened, as before; the consequence of which is, that the piston again descends; and in this manner the alternations repeatedly take place. The principal augmentation of power in this engine, compared with that of Newcomen, arises from the cylinder not being cooled by the injection water, from its being practicable to use steam, which is more powerful than the pressure of the atmosphere, and from the employing of this steam both to elevate and to depress the piston. In general, these engines are worked by steam, which would support a column of four or five inches of mercury besides the pressure of the atmosphere, and sometimes more.

All the engines which were constructed before the time of Mr. Watt were employed merely for raising water, and were never used as the first movers of machinery; except indeed, that Mr. R. Fitzgerald published in the Transactions of the Royal Society, a method of converting the irregular motion of the beam into a continued rotatory motion, by means of a crank and a train of wheel-work connected with a large and massy fly, which by accumulating the pressure of the machine during the working stroke, urged round the machinery during the returning stroke, when there is no force pressing it forward. For this new and ingenious contrivance, Mr. Fitzgerald received a patent, and proposed to apply the steam engine as the moving power of every kind of machinery; but it does not appear that any mills were erected under this patent. In order to convert the reciprocating motion of the beam into a circular motion, Mr. Watt has a contrivance far more simple, as may be seen by inspecting any of the numerous engravings of his machinery.

The strides which steam is making in the economy of the country, are more gigantic and surprising than those who are domesticated at a distance from its immediate operation imagine; but the capability of the locomotive engine to travel, with ease and safety, with a weight of ninety tons in its train, at the rate of eight miles an hour, having been proved by the opening of the Darlington and Stockton rail-road, the following particulars of its powers and advantages may not be unacceptable to the reader:—The engine will travel over 25 miles seven times a day, making 175 miles a day's work, with 90 tons, consuming seven tons of small coals each day, or 42 tons per week; which, at an average cost of 7s., £14. 14s. will be the expense. One man and a boy in constant attendance, supposing the 24 hours equal to three days, will be three men and thirteen boys each day, at 16s. 6d.; this will add £5. 3s. 6d. making the total weekly expense £19. 17s. 6d. The engine will cost £600, 80 waggons £900,—giving £1500 for the entire set out. Now, 90 tons will load six boats, each of these boats will be a day in performing 20 miles; therefore 52 boats, with 52 horses, 52 men, and 52 boys, will be required to execute the transfer of 90 tons 175 miles in one day. Each horse will cost weekly one guinea, each man a guinea, and each boy 12s. forming a total weekly charge of £140. 8s. in lieu of £19. 17s. 6d. The 52 boats and horses will be worth £10,000, and requiring a considerably greater amount to keep them in repair, throwing a balance of full £7000 per annum in favour of every locomotive engine that may be used. How many may eventually be at work, it would be difficult to conjecture; but as forty would be required to work the London, Birmingham, and Liverpool, and the Manchester and Stockport lines, in all probability not less than 500 would be employed; and as the saving on every five engines would be equal to the interest of one million, the 500 would put the people yearly in possession of a sum as great as the interest of one hundred millions sterling, independently of the advantage of speed, and of the great saving of tonnage, the rail-road lines being one-third shorter than the canals in use. Finally, 1000 persons may be conveyed one mile, or one person 1000 miles, by locomotive engines, at the rate of eight miles an hour, at a cost of something less than five pence.

In addition to the improvements made by Watt on his original invention, many others are highly deserving of notice; but the

Parts of a 12 Horse Steam Engine, by Rothwell, Hick, & Rothwell. BOLT

p. 361.

whole are too numerous to admit in detail. During the last twenty years, scarcely a month has elapsed in which some new modification has not been proposed, among which, several have been found highly beneficial. The names of Witty, Bettancourt, Moyle, Trevithick, Woolf, Evans, Perkins, and others, will never be forgotten while the steam-engine is remembered, and shall retain its use; but their respective merits we cannot find room to enumerate.

Of the steam-engine described in the following paragraphs, and illustrated in the plates, we have been furnished with an account by Mr. Hick, whose name it bears:—

"Twelve Horse Portable Steam-Engine, as manufactured by Rothwell, Hick, and Rothwell, engineers, Bolton, Lancashire. Steam cylinder 10½ inches diameter; 4 foot stroke; 27 strokes in a minute."

"This engine consists, in the first place, of a large cast iron plate, firmly bolted down to stone or brick work, on which the whole of the materials are fixed. The beam, with all its appendages, is by this means supported without being at all connected with the building, by a double diagonal frame, one half only of which can be seen in the drawing. These frames are surmounted by an entablature plate, to which the bearers or spring beams are attached that receive the studs or centers of the radius rods of the parallel motion, the extreme ends of which are supported by a pillar resting on a bracket projecting from the back of the cylinder. The pedestals in which the gudgeon of the beam works, rest on the entablature plate, and are firmly secured by bolts passing through the whole. The side walls on which the foundation plate acts, are so far asunder as to allow a sufficiently wide recess to receive the condensing cistern, with its air-pump and condenser, hot and cold water pumps, as well as to afford room for getting down to secure the ends of the bolts. The governor is supported by a standard placed directly over the crank shaft, and is turned by a single pair of bevel wheels. The upper part of it is hollow, to receive a small rod that is attached by a cross pin to a brass sliding socket, which is connected with the governor arms by two small links, and partakes of the motion communicated to them by the movement of the balls. The small rod has a communication with the throttle valves, by means of the levers fixed to the ceiling of the engine-house.

"The annexed engraving represents a steam-engine of twelve horses' power, with a cross section of its boiler A, about two-thirds filled with water. The boiler is oblong, 12 feet by 5½ feet, and the flame, after acting upon the whole length of the bottom, is conducted entirely over the whole surface of the sides and ends, by means of the brick flues, (which are wide enough to admit a person to get in, to clean them when requisite,) before its entrance to the chimney.

"In the flue near to the chimney, is placed a damper or plate, moving perpendicularly in two grooves, in such a manner as entirely to stop the draft when shut. This damper is suspended by a chain passing over two pulleys, at the opposite end of which is attached a hollow iron float, that moves up or down in a pipe fixed on the top of the boiler, exactly in proportion to the height of the column of water in the pipe, that the strength of the steam is capable of supporting, which rising in height as the strength of the steam increases, raises the float, and causes the damper to descend, thereby lessening the draft, and *vice versa*. To this apparatus a bell is sometimes connected, to give notice of the time when it is necessary to throw an additional quantity of coals upon the fire.

"In order to prevent any stoppage of the engine when it might be necessary to repair a boiler, two are now generally adopted, and the box B on the boiler top, which contains a stop valve, is prepared with an additional branch, to communicate with a second boiler. On the steam pipe, and leading to the cylinder, is placed a box containing a valve opening upwards, called a safety valve, and so weighted as to rise and let the steam escape when it is stronger than the engine requires.

"The steam cylinder and its casing are cast together in one piece. A section of which, in plate 2, will explain the construction of this important part of the engine, as well as the peculiar construction of the valves for admitting the steam alternately to act on contrary sides of the piston. The space betwixt the

cylinder and the casing being constantly filled with steam, prevents any condensation taking place within the cylinder, and serves also as a conducting pipe for the steam to the boxes E, containing the sliding valves, (which are generally called D valves, from their resemblance in form to that letter,) through two separate openings for that purpose, in each of which is placed a throttle valve, and on their spindles are levers communicating by a rod with the governor for the purpose of regulating the speed of the engine.

"The valves F are packed on their circular sides with a soft substance of hemp or flax, and in consequence of the steam being admitted to the *under* side of the top valve, and the *upper* side of the bottom valve, they of course require no more force to move them than what is necessary to overcome the friction of the packing and the surface over which they slide. The weight of the valves and their rods are accurately counter-balanced by a moveable weight or a lever under the cylinder, and are moved by an eccentric circle, or the fly-wheel shaft, which is shewn on an enlarged scale in plate 2. By the arrangement of having two throttle valves, the least difference in weight between those parts of the engine that are attached to the opposite ends of the working beam, can be regulated, by allowing a little more steam to pass in the same time through either of the valves, as may be found necessary, thereby equalizing as much as possible the action of the engine. One pipe, G, only is required in front of the cylinder, and that for the purpose of conducting the steam from the upper side of the piston to the condenser H,—a vessel in which the condensation of the steam is effected after its escape from the cylinder, by admitting a quantity of cold water out of the condensing cistern I, through an injection cock, the opening of which is regulated by hand. The condensing cistern is supplied with water by the cold-water pump K.

"The air pump, (or, more properly, discharging pump,) for the purpose of removing the water from the condenser after its admixture with the steam, and keeping up a constant vacuum, with its valves and bucket, will be fully understood by a reference to plate 2, as well as L, the hot-water pump, used for raising water to supply the boiler, which water passes through a small valve, and down the same pipe that contains the damper float. This valve is connected with a lever, having one of its ends connected by a rod passing through a pipe with a stone float, that rises and falls with the surface of the water in the boiler, and thereby admitting a smaller or larger quantity of water, as may be requisite. This pipe, for the rod to pass through, has several advantages over the method of passing it through a *stuffing box* on the boiler top, as in case the hot water pump by any accident should cease to act, and the water get low in the boiler, the steam would make its escape before any serious injury could happen, shewing instantly that such was the fact the moment it got below the end of the pipe. The friction between the rod and the water being so trifling, insures an almost uniform regularity of action.

"The little apparatus M, or self-acting water gauge, consists of a standard fixed on the boiler top, with a pulley, over which a chain passes connected at one end with a copper wire, and a stone float, which by its rising or falling indicates the exact variation that takes place in the height of the surface of the water, and is used in lieu of the gauge pipes and cocks formerly applied for that purpose, over which it has this great advantage, that besides shewing the water to be too high or too low, it shews exactly how much, by the pointer and scale that are affixed to it.

"N, a small cistern containing the blow valve, for the purpose of allowing the air to escape from the cylinder, &c. previous to the engine being set to work.

"The crank P in o is made globular, to prevent any strain in case the shaft should get out of its level position by the unequal wearing of the brass steps under its tunnels, or any little sinking of the foundation."

"In order to prevent the accidents occasioned by the bursting of steam boilers, which are of such frequent occurrence, I must now solicit a little attention to the drawing and description of a self-acting safety valve, of my invention, or rather the application of it to a new purpose: for a similar valve has been used, as a clack for a pump upwards of a hundred

years; and it will easily be perceived from the several advantages it possesses, that wherever its adoption shall take place it will be scarcely possible for any accident of this nature to arise.

"The opening in the lower part of the box, which is fixed on the boiler top, or, if more convenient, on any part of a pipe having a free communication with it, requires to be of such a size as to allow a free discharge of all the steam the boiler is capable of generating. This opening is covered with a spherical valve, the outer part of brass, which is filled with lead, of such dimensions, and consequently of such weight, as to press with as many pounds per square inch, as it is intended the strength of the steam at a *maximum* in the boiler should ever be raised to. Now, as it is perfectly free from friction, the obvious effect will be, that at the very instant the steam arrives at this degree of pressure, the ball will be raised by its force, and a discharge will immediately take place.

"The plate *b*, which is large enough to cover entirely the ball or valve, and thereby prevent its being pressed down, or at all interfered with, even by any bar or rod being forced down the discharging pipe, is connected with the cover by small bars *c*. The projections *a* are merely to prevent the ball at any time from being thrown off its seat. Originally the steam was discharged at the side-opening *d*, but this will be rendered unnecessary if the plan be adopted which has the discharging pipe in the lid or cover of the box, but both are drawn to shew the different methods of taking away the steam, and the selection must be made according to convenience, and the judgment of the engineer.

"From the nature of its construction, this safety valve, requiring no packing or attention, can be entirely secured from the officious meddling and carelessness of attendants; and a pipe may be attached to the opening in the box, and continued into the chimney, or any other convenient place of discharge. I should not recommend this valve to be used as a substitute for the ordinary safety valve, (improperly so called,) but in all cases in addition, and so loaded as only to be brought into action at a very trifling additional pressure above that to which the other valve is weighted. This valve would be found of the greatest advantage, in preventing the boiling over of the feed pipes of boilers, when the rooms over them are used as drying stoves in print-works, bleach-works, &c. I ought to state, that I have had this description of valve in use upwards of four years, with the greatest regularity of action."

First Steam Boat.—Although it is only of late years that steam has been extensively applied to the propelling of vessels on water, yet, a knowledge of its capabilities for this purpose is of old date. As far back as the 21st of December 1736, Mr. Jonathan Hulls took out a patent for "A new-invented Machine for carrying Vessels or Ships out of, or into, any Harbour, Port, or River, against Wind and Tide, or in a Calm;" and in the following year, he published a pamphlet in London, detailing at length the nature of his invention, which was nothing else than a tow-boat moved by steam, as represented in the annexed engraving. The description of the mode of working it we shall give in his own words.

In some convenient part of the tow-boat, there is placed a vessel, about two-thirds full of water, with the top close shut. This vessel being kept boiling, rarefies the water into a steam. This steam being conveyed through a large pipe into a cylindrical vessel, and there condensed, makes a vacuum, which causes the atmosphere to press on this vessel, and so presses down a piston that is fitted into the cylindrical vessel, in the same manner as Mr. Newcomen's engine with which he raises the water by fire.

"Fig. 1, P, is the pipe coming from the furnace to the cylinder. Q, is the cylinder wherein the steam is condensed. R, the valve that stops the steam from coming into the cylinder whilst the steam within the same is condensed. S, the pipe to convey the condensing water into the cylinder. T, a cock to let in the condensing water when the cylinder is full of steam, and the valve P is shut. U, a rope fixed to the piston that slides up and down the cylinder.

"Note.—This rope U is the same rope that goes round the wheel D in the machine fig. 2.

"Fig. A the chimney coming from the furnace. B the tow-boat. C C two pieces of timber, framed together to carry the

machine. D a D and D b are three wheels on one axis, to receive the ropes M f l and F a. H a and H b are two wheels on the same axis with the fans I I I I I, and move alternately in such a manner, that, when the wheels D a D and D b move backward or forward, they keep the fans in a direct motion. P f is a rope going from H b to D b, that when the wheels D a D and D b move forward, moves the wheel H b forwards, which brings the fans forward with it. F a is a rope going from the wheel H a to the wheel D a, that, when the wheels D a and D b move forward, the wheel H a draws the rope F, and raises the weight G, at the same time as the wheel H b brings the fans forward. When the weight G is so raised, while the wheels D a D and D b are moving backward, the rope F a gives way, and the power of the weight G, brings the wheel H a forward and the fans with it, so that the fans always keep going forward, notwithstanding the wheels D a D and D b move backwards and forwards as the piston moves up and down in the cylinder. L l are teeth for a catch to drop in from the axis, and are so contrived, that they catch in an alternate manner to cause the fans to move always forward for the wheel H a, by the power of the weight G, is performing its office, while the other wheel H b goes back in order to fetch another stroke."

The next attempt was that of Mr. Symington. In his boat, by placing the cylinder nearly in a horizontal position, the introduction of a beam is avoided. The piston is supported in its position by friction wheels, and communicates by means of a joint with a crank, connected with a wheel, which gives the water-wheel, by means of its teeth, a motion somewhat slower than its own; the water-wheel serving also as a fly. This water-wheel is situated in a cavity near the stern, and in the middle of the breadth of the boat, so that it becomes necessary to have two rudders, one on each side, connected together by rods, which are moved by a winch near the head of the boat, so that the person who attends the engine may also steer. Mr. Symington likewise placed an arrangement of stampers at the head of the boat, for the purpose of breaking the ice on canals, an operation often attended with great labour and expense. These stampers were raised in succession by levers, the ends of which were depressed by the pins of wheels turned by an axis communicating with the water-wheel. A drawing of this steam-boat is given in vol. i. of Dr. Young's Natural Philosophy.

The first steam-boat in America was launched at New York on the 3d of October 1807, and began to ply on the river between that city and Albany, a distance of about 120 miles.

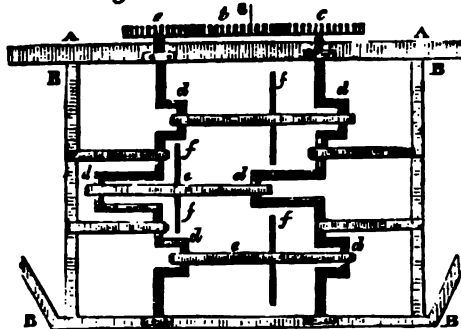

In the common wheel paddles at present employed for propelling steam-boats, "there are, it appears to me, (says Mr. Clark,) two defects, which are yet left to the ingenuity of the mechanic to remove. In the first place, they are defective, on account of the declivity with which they enter and come out of the water. In the second place, the successive paddles are commonly placed so very near one another, that when one paddle enters the water, it leaves, by its swift motion, a current, into which the next paddle enters; which, instead

of moving in an opposite direction to the paddles, moves in the same. Great resistance is thus lost. To remedy the former of these defects, several attempts have been made in this country. These attempts, however, have commonly been unsuccessful, on account of the great contingency of force which steam-boat paddles are called to bear. The latter of the defects which I have stated, has not, however, so far as I am aware, met the attention of the mechanics of this country.

"About two years ago, I made some attempts at the removal of these defects. The following is an account of one of the plans which occurred to me.

"Fig. 2 is a plan of the machine; fig. 3 is a sectional view. The same letters refer to both. A A fig. 2, is the side of the boat. B B, B B, figs. 2 and 3, is the frame to support the machinery.

Fig. 2.

a is the shaft which turns the wheel b, whose teeth run into those of the wheels c c, and turn both in the same direction. These wheels are connected, by a shaft, with the double cranks d d d, d d d. These cranks are inclined to one another, at equal angles, and are of equal lengths. e e e are bars, connecting these cranks in such a manner as to preserve the corresponding cranks on the different shafts, parallel to one another, as shewn in fig. 3, f f f are paddles affixed perpendicularly to these bars. These paddles alone, or the paddles and the bars together, may be so fixed as to be removable at pleasure."

Fig. 3.

From this description, it is evident that the cranks on the same shaft will always preserve the same inclination to one another; that the corresponding ones on different shafts will always be parallel; that the bars connecting them will always be horizontal; and consequently that the paddles must always enter, pass through, and rise out of the water, perpendicularly to its surface. The terminations of the paddles move in a circle, as represented in fig. 3 by a dotted line. The radius of this circle is equal to the length of any of the several cranks. It is evident, also, that every successive paddle enters in a current different from that caused by the one which it follows.

Of an excellent plan for the consuming of smoke, invented by Mr. Chapman, of Whithy, and for which he was rewarded with the large silver medal by the Society of Arts, the following is his account:—

"It is well known to all that are conversant on the subject, that it is necessary to admit a proportion of pure atmospheric air, to unite with the smoke after it is generated in the furnace, in order to supply the oxygen gas, without which it will not inflame. It is likewise known that any air admitted into the body of the furnace, if it does not go through the burning fuel, has a great tendency to cool the bottom of the boiler, and retard the generation of steam. To obviate this, it is the general

practice, in the construction of those furnaces which consume the smoke, to admit the air partly at the ash-pit, and partly up through the fire-bridge. I offer, for the consideration of the Society, an improved plan, which I have adopted, and which has answered beyond my utmost expectations. It is as follows:—

"To heat the air before its admission into the furnace. This I do by casting the grate bars hollow from end to end, so that they form a series of parallel tubes, which open in two boxes, one placed in front, and the other behind the grate. In the front box, directly under the fire-door, I make a register to open and shut, to any extent, at pleasure. The other end I connect with the brickwork directly underneath the fire-bridge, which fire-bridge I make double, with a small interval between, say one inch; the interval to go across the furnace from side to side, and rather to incline forward, or towards the fire-door, so as to meet and reverberate the smoke on to the ignited fuel in the grate, which causes it to inflame and become a sheet of bright fire under the bottom of the boiler. From what I have said it will appear, that if the front register is open, or partially so, there will be a great draught of air through it, along the interior of the grate bars, thence into the flue of the fire-bridge, and out of the orifice at top, which air will be heated in its passage through the bars, before it comes in contact with the smoke, when it will give out its oxygen, and cause it to inflame.

"Such was my view of this part of the subject in theory, and I have found it to succeed in practice, in a small engine of my own. But a further improvement was necessary to make it quite perfect. There are few people who are aware of the extent of the mischief arising from the old method of charging a grate by the front door. Now, in my engine, (which has only two-horse power), I calculated that every time the fire-door was opened, to stir the fire and replenish the fuel, there could not be less than from forty-five to fifty feet of cold atmospheric air admitted into the furnace, which so cooled the heated gases, &c. that, however complete the plan was in other respects, the smoke could not possibly inflame, from being so cooled, till a considerable time after the fire-door was shut.

"To obviate this, I have adopted a cast iron hopper above the fire-door, with a type at the bottom, that has two pivots at one side and open at the other; one pivot goes through the end of the hopper, and has a counter-lever to keep the type shut when a sufficient quantity of coal for a charge is on it. The top of the hopper is covered with a lid, which I shut down during the time of firing, then, by lifting the lever which opens the type inside, the coals slide down on to the fore end of the grate bars, which is only the work of a moment. It is evident that no quantity of cold air can thus get into the furnace; in fact, it is not possible for any person that does not see the operation of firing to know when fresh fuel is added by looking at the top of the chimney. The smoke that issues is never more than a light gray, just perceptible, but in a general way is not seen at all.

"The coals last admitted, after lying a short time at the front of the more ignited fuel, become partially coked, and just before I admit a fresh supply, I push the last charge further along the grate, by a tool made for the purpose, which remains constantly in the furnace. It consists of a plate of iron about four inches broad; its length goes across the grate with a round bar of iron riveted into its centre, at right angles, to form a handle, which comes through a hole made at the bottom of the fire-door, and is long enough for a man to use with both hands, so that he can either push from, or pull towards him, to manage the fire within, without opening the fire door, except when the grate wants cleaning, &c. &c. For better knowing when the fire wants stirring or replenishing, I have a hole, about an inch in diameter, in the fire door, to look through, covered by a piece of iron which hangs by a rivet above. After I have used the above instrument, I pull it up close to the fire-door, where it remains till it is again wanted; and the coals, when let into the fire, fall down beyond it.

"The above-written account constitutes the whole of my improvements, as far as is required by the Society, but not the whole of the advantages gained by my invention. For instance, the durability of the grate bars by the admission of air through them. I may add, that I examined my own yesterday, and I do not find them any worse, although they have been in use for four months."

STEAM PRINTING. See **PRINTING BY STEAM.**

STEATITES, in Mineralogy, is usually amorphous, but sometimes crystallized in six-sided prisms. Its texture is commonly earthy; specific gravity 2.61 to 2.79; feels greasy; seldom adheres to the tongue; colour white or gray, with a tint of other colours; the foliated green.

STEEL, a most valuable metal, consisting of iron combined with carbon. It is chiefly used for edge-tools, and other sharp and cutting instruments where hardness is required; and from the fine polish of which it is susceptible, it is used in ornaments of various kinds. By heating steel to redness, and cooling it suddenly, it can be made much harder than any other metal; and if heated to a lower temperature than redness, and suddenly cooled, it becomes the most elastic of all the metals.

STEELING, in Cutlery, the laying on a piece of steel upon a larger mass of iron, that the part which is to receive the edge, may be harder than the rest.

STEELEYARD, a kind of balance, called also the Roman balance, by means of which the gravities of different bodies are found by a single weight being placed on the lever or beam, so as to secure an equilibrium; the notches and figures marked on it, denoting the number of pounds.

STEELYARD Spring, a kind of portable balance, serving to weigh any article not exceeding forty pounds. It is composed of a brass tube, in which is a rod, round which is wound a spring of tempered steel, in a spiral form. On this rod are marked pounds, and the divisions of pounds, and to the part of the rod at the bottom of the tube, is a hook, on which the article to be weighed, is fastened. Now, the other part of the rod being made fast to the spiral spring, it must be obvious that the greater the weight which is attached to the hook, the more will the spring be pressed and contracted; and consequently the greater will be the part of the rod drawn out of the tube, on which are marked the number of pounds that have thus drawn it out.

STEEPLE, an appendage to a church, generally raised at the western end, for ornament, and also to hold the bells. Both towers and spires come under the denomination of steeple.

STEERAGE, an apartment before the great cabin, from which it is separated by a partition or bulk-head. In merchant-ships it is generally the habitation of the inferior officers and crew; but in ships of war it serves only as a hall or antichamber to the great or captain's cabin. *Steerage*, is also used to express the effort of the helm. *Steerage-Way*, implies a sufficient degree of motion communicated to a ship for her to become susceptible of the effects of the helm in governing her course.

STEERING, may be defined the art of directing a ship's way by the movements of the helm, or of applying its efforts to regulate her course when she advances. The perfection of steering, consists in a vigilant attention to the motion of the ship's head, so as to check every deviation from the line of her course in the first instant of its motion, and in applying as little of the power of the helm as possible. By this she will run more uniformly in a straight path, as declining less to the right and left; whereas, if a greater effort of the helm is employed, it will produce a greater declination from the course, and not only increase the difficulty of steering, but also make a crooked and irregular track through the water. The phrases used in steering a ship vary according to the relation of the wind to her course. Thus, if the wind is fair or large, the phrases used by the pilot or officer who superintends the steerage, are Port, Starboard, and Steady. The first is intended to direct the ship's course farther to the right, the second is to guide her further to the left, and the last is designed to keep her exactly in the line on which she advances, according to her prescribed course. The excess of the first and second movement is called *Hard-a-Port*, and *Hard-a-Starboard*; the former of which gives the greatest possible inclination to the right, and the latter an equal tendency to the left. If, on the contrary, the wind is foul and scant, the phrases then used are *Luff*, *Thus*, and *No-Near*. The first of which is the order to keep her close to the wind; the second, to retain her in her present situation; and the third, to keep her sails full. In ships of war, the duties of conning and steering are divided amongst the quarter-masters, their mates, and the most expert seamen, who attend the helms

in turns. The steerage is constantly supervised by the quarter-masters. In merchant-ships, every seaman takes his turn in steering, being directed therein by the mate of the watch, or some other officer. As the safety of a ship, and all contained therein, depend in a great measure on the steerage and effects of the helm, the apparatus by which it is managed should often be examined by the proper officers. Indeed, when the fatal effects which may result from negligence in this important duty are duly considered, such inattention must be pronounced pardonable.

STEERSMAN, the helmsman, or timoneer; which latter appellation is derived from the French term, which signifies an helmsman. He is reckoned the best steersman who uses the least motion in putting the helm over to and again, and who keeps the ship best from making yaws, that is, from running in and out. For this purpose, he should diligently watch the movements of the head by the land, clouds, moon, or stars; because, although the course is in general regulated by compass, the vibrations of the needle are not so quickly perceived, as the sallies of the ship's head to the right or left, which, if not immediately restrained, will require additional velocity in every instant of their motion, and demand a more powerful impulse of the helm to reduce them; the application of which will operate to turn her head as far on the contrary side of her course.

STEEVING, the angle of elevation which a ship's bowsprit makes with the horizon.

STEM, a circular piece of timber, into which the two sides of a ship are united at the fore end; the lower end of it is scarfed to the keel, and the bowsprit rests upon its upper end; the ends of the wales and planks of the sides and bottom are let into a groove or channel cut in the middle of its surface, from top to bottom. The outside of the stem is usually marked with a scale of feet, answering to a perpendicular from the keel. Its use is to ascertain the draught of water at its fore part, when the ship is in preparation for a sea voyage, &c. The stem at its lower end is of equal breadth and thickness with the keel, but it grows proportionally broader and thicker towards its upper extremity. *False Stem*, is that fixed before the right one. When a ship's stem is too flat, so that she cannot keep a wind well, they put a false stem above, which makes her rid more way, and bear a better sail. *To Stem a Tide*, to acquire a velocity in sailing against the tide equal to the force of the current. *From Stem to Stern*, from one end of the ship to the other.

STEM. See **STALK.**

STEMMATA, in the history of insects, are three smooth hemispheric dots, placed generally on the top of the head, as in most of the hymenoptera and other classes.

STEMSON, an arching piece of timber fixed within the apron, to reinforce the scarf thereof, in the same manner as the apron supports the scarf of the stem.

STENOGRAPHY. The art of short-hand writing. The following scheme is that which has received most general approbation from its simplicity, and being founded on rational principles, by which it is easily acquired and retained.

Rules for Orthography in Short Hand.—All quiescent consonants in words are to be dropped; and the orthography to be directed only by the pronunciation; which being known to all, will render this art attainable by those who cannot spell with precision in long hand. 2. When the absence of consonants not entirely dormant can be easily known, they may often be omitted without the least obscurity. 3. Two, or sometimes more consonants, may, to promote greater expedition, be exchanged for a single one of nearly similar sound, and no ambiguity as to the meaning ensue. 4. When two consonants of the same kind or same sound come together, without any vowel between them, only one is to be expressed; but if a vowel or vowels intervene, both are to be written; only observe, if they are perpendicular, horizontal, or oblique lines, they must only be drawn a size longer than usual; and characters with slopes must have the sides of their heads doubled. See **PLATE**.

Might is to be written mit, fight, fit, machine, manish, enough, enuf, laugh, laf, prophet, profet, physics, fisika, foreign, foren, sovereign, sovren, psalm, sam, receipt, resot, write rite, island, iland. In short, all that the short-hand writer has to do with

orthography, is to produce the clear and distinct sound of his word in the shortest and most compact manner possible.

1. Vowels, being only simple articulate sounds, though they are the connectives of consonants, and employed in every word and every syllable, are not necessary to be inserted in the middle of words; because the consonants if fully pronounced, with the assistance of connexion, will always discover the meaning of a word, and make the writing perfectly legible. 2. If a vowel is not strongly accented in the incipient syllable of a word, or if it is mute in the final, it is likewise to be omitted; because the sound of the incipient vowel is often implied in that of the first consonant, which will consequently supply its place. 3. But if the vowel constitutes the first or last syllable of a word, or is strongly accented at its beginning or end, that vowel is continually to be written. 4. If a word begin or end with two or more vowels, though separated, or when there is a coalition of vowels, as in diphthongs and triphthongs, only one of them is to be expressed, which must be that which agrees best with the pronunciation. 5. In monosyllables, if they begin or end with a vowel, it is always to be inserted, unless the vowel *e* is mute at the end of a word.

The short-hand alphabet consists of 18 distinct characters, taken from lines and semicircular curves; the formation and application of which we shall now explain, beginning with the vowels. For the three first vowels *a*, *e*, and *i*, a comma is appropriated in different positions; and for the other three *o*, *u*, and *y*, a point. The comma and point, when applied to *a* and *o*, is to be placed as in the plate, at the top of the next character; when for *e* and *u* opposite to the middle; and when for *i* and *y* at the bottom. Simple lines may be drawn four different ways perpendicular, horizontal, and with an angle of about 45 degrees to the right and left. An ascending oblique line to the right, which will be perfectly distinct from the rest when joined to any other character, may likewise be admitted. These characters being the simplest in nature, are assigned to those five consonants which most frequently occur, *viz*, *l*, *r*, *t*, *c* hard, or *k*, and *e* soft, or *s*. Every circle may be divided with a perpendicular and horizontal line, so as to form likewise four distinct characters. These being the next to lines in the simplicity of their formation, we have appropriated them for *b*, *d*, *n*, and *m*.

The characters expressing nine of the consonants are all perfectly distinct from one another; eight only remain which are needful, *viz*, *f*, *g*, or *j*, *h*, *p*, *q*, *v*, *w*, and *x*, to find characters for which we must have recourse to mixed curves and lines. The characters which we have adopted are the simplest in nature after those already applied, admit of the easiest joining, and tend to preserve lineality and beauty in the writing. It must be observed, that we have no character for *c* when it has a hard sound as in castle, or soft as in city; for it naturally takes the sound of *k* or *s*, which in all cases will be sufficient to supply its place. *R* likewise is represented by the same character as *l*; only with this difference, *r* is written with such an ascending stroke, and *l* with a descending: which is always to be known from the manner of its union with the following character; but in a few monosyllables where *r* is the only consonant in the word, and consequently stands alone, it is to be made as is shewn in the alphabet, for distinction's sake. *Z*, as it is a letter seldom employed in the English language, and only a coarser and harder expression of *s*, must be supplied by *s* when ever it occurs; as for Zedekiah, write Sedekiah, &c.

4. The terminative character for tion, sion, cion cian, tian, is to be expressed by a small circle joined to the nearest letter and turned to the right. 5. The terminative character for ing is to be expressed likewise by a small circle but drawn to the left hand, and its plural *ings* by a dot. 6. The plural sign *s* is to be added to the terminative characters when necessary. 7. The separated terminations are never to be used but in polysyllables, or in words of more syllables than one.

The following is the explanation of the different arbitrariness and abbreviations in the plate:—No. 1, As—2, Nation—3, Thing—4, Circumstance—5, Counterfeit—6, Visible—7, Himself—8, Themselves—9, Atonement—10, Therefore—11, Christ—12, Multitude—13, Descendants—14, Government—15, Everlasting.

The most usual abbreviation, is to use the full letter of a word with a dot under it, to show it is an abbreviation.

STEP, a block of wood fixed on the decks or bottom of a ship, and having a hole in its upper side fitted to receive the heel of a mast or capstan. To *Step a Boat's Mast*, is to erect and secure it in readiness for setting sail.

STEREOGRAPHY, the art of drawing the forms and figures of the solids upon a plane.

STEREOMETRY, that part of geometry which teaches how to measure solid bodies, that is, to find the solidity or solid contents of bodies, as globes, cylinders, cubes, vessels, ships, &c.

STEREOTYPE PRINTING. The mode of stereotype printing is first to set up a page, for instance, in the common way, and when it is rendered perfectly correct, a cast is taken from it, and in this cast the metal for the plate is poured: the plates thus procured are afterwards worked on blocks in the common way.

STERILITY, the state of that which is barren, whether animal or vegetable, in opposition to fecundity or fruitfulness.

STERLING. A pound, shilling, or penny, sterling, signifies as much as a pound, shilling, or penny, of lawful money of Great Britain as settled by authority.

STERN, the posterior part of a ship, or that part which is presented to the view of a spectator, placed on the continuation of the keel, behind. The stern is terminated by the taffarel above, and by the counters below. It is limited on the sides by the quarter-pieces, and the intermediate space comprehends the galleries and windows of the different cabins.

STERN-FAST, a rope used to confine the stern of a ship, lighter, or boat, to any wharf or jetty-head, &c.

STERN-FRAME, the several pieces of timber which form the stern.

STERNMOST, implies any ship or ships that are in the rear or farthest astern, as opposed to headmost.

STERN-POST, a long straight piece of timber, erected on the extremity of the keel, to sustain the rudder, and terminate the ship behind. It is usually marked like the stem with a scale of feet, from the keel upwards, in order to ascertain the draught of water abaft. This piece ought to be well served and supported, because the ends of all the lower planks of the ship's bottom are fixed in a channel cut on its surface, and the whole weight of the rudder is sustained by it. The difficulty of procuring a stern-post of sufficient breadth in one piece, has introduced the practice of fixing an additional piece behind it, which is strongly bolted to the former; the hinges which support the rudder are accordingly fixed to this latter, which is also tenoned into the keel, and is denominated the back of the post. The stern-post is strongly attached to the keel by a knee, of which one branch extends along the keel, being scarfed to the dead-wood, and fore-locked under the keel, whilst the other branch inclines upwards, and corresponds with the inside or fore part of the stern-post, to which it is also bolted in the same manner.

STERN-SHEETS, that part of a boat which is contained between the stern and the aftmost seat of the towers. It is generally furnished with seats to accommodate passengers.

STERN-WAY, the movement by which a ship retreats or goes backward with her stern foremost.

STERNA, the *Tern*, in Natural History, a genus of birds of the order anseres. There are twenty-five species. The following are the principal: *S. caspia*, or the Caspian tern. This abounds on the seas wherein it derives its name. It fishes also in rivers, and sometimes suddenly darts upon its prey from a considerable height, and at other times skims the surface of the water in the manner of a swallow. It is nearly two feet in length. It lays only two eggs, and its sound resembles those of a person laughing.—The moody, is a foot and a quarter long, and is frequently met with at sea, between the tropics.—The great tern, is found in various parts of Europe, and in summer on the British coasts. It is fourteen inches long. Its manners on the water resemble those of the swallow by land.

STEWARD, in Naval affairs, is an officer in a ship of war, appointed by the purser to distribute the different species of provisions to the officers and crew, for which purpose he is furnished with several assistants. He is generally denominated the purser's steward, or the ship's steward, to distinguish him from the captain's or the ward-room stewards, who are appointed to take care of the sea-stock belonging to the captains and lieutenants, &c.

STEWARD, a man appointed in a place or stead, and always signifies a principal officer within his jurisdiction.

STICK, GOLD. An officer of superior rank in the life-guards, so called, who is in immediate attendance upon the king's person. When his majesty gives either of his regiments of life-guards to an officer, he presents him with a gold stick. The colonels of the two regiments wait alternately month and month. The one on duty is then called gold stick in waiting, and all orders relating to the life-guards are transmitted through him. During that month he commands the brigade, receives all reports, and communicates them to the king. This temporary command of the brigade does not, however, interfere with the promotion that may be going forward, as each colonel lays those of his own particular corps before his majesty. Formerly the gold stick commanded all guards about his majesty's person. On levees and drawing room days, he goes into the king's closet for the parol.

STICK, Silver. The field-officer of the life-guards when on duty is so called. The silver stick is in waiting for a week, during which period all reports are made through him to the gold stick; and orders from the gold stick pass through him to the brigade. In the absence of the gold stick, on levees and drawing-room days, he goes into the king's closet for the parol.

STIFF, the quality by which a ship is enabled to carry a sufficient quantity of sail without oversetting.

STIGMA, in Entomology, a spot or anastomosis in the middle of the wings of insects, near the anterior margin, conspicuous in the hymenopterous tribes.

STIGMATA, in Natural History, the apertures in different parts of the bodies of insects, communicating with the tracheæ or air-vessels, and serving for the office of respiration.

STILL, the name of an apparatus used in distillation. See **DISTILLATION**.

STIMULANT, in Medicine, any agent which has the property of increasing the mobility, or of exciting the motions of the living body, or its moving parts.

STING, an apparatus in the body of certain insects, in form of a little spear, serving them as a weapon of offence.

STINK-POT, an earthen jar, charged with powder, grenades, and other materials of an offensive and suffocating smell. It is sometimes used by privateers, to annoy an enemy whom they design to board. See the article **BOARDING**.

STIPPLING, a mode of engraving on copper by means of dots, as contradistinguished from a course of continued lines.

STITCH, in Agriculture, a ridge or butt in a field which is under the plough. The dimensions of a stitch are liable to many variations in different districts.

STOAT, in Zoology, the name of an animal whose skin is the ermine. These creatures are plentiful in Russia and Norway, where an extensive trade in their skins is carried on. Their fur changes colour with the seasons of the year. When the snow is on the ground, its celebrated whiteness appears to the greatest advantage.

STOCK, generally implies provisions procured by individuals, for the particular accommodation of themselves or messmates; hence we say, fresh stock, sea stock, live stock.

STOCKINGS, the clothing of the leg and foot. Anciently stockings were made of cloth or milled stuff sewed together, but since the knitting and weaving of stockings have been invented, cloth has been entirely laid aside. Henry II. of France, in 1559, was the first who wore silk stockings. Henry VIII. and Queen Elizabeth, were the first who wore silk stockings in England, and these were brought from Spain, where the invention seems to have had its birth. In the third year of Elizabeth, the art of knitting was introduced into England, and to this honour the Scotch lay claim. The stocking loom is generally thought to have been invented by William Lee, M. A. of St. John's College, Cambridge, a native of Woodborough, near Nottingham, in the year 1589; but receiving little encouragement, and being in indigent circumstances, he went to France, where, meeting with further disappointment, he died of a broken heart.

STOCKS, a frame erected on the shore of a river, whereon to build shipping. It generally consists of a number of wooden blocks ranged parallel to each other at convenient distances, and with a gradual declivity towards the water.

STOCKS, the public funds of the nation, instituted for the purpose of paying the interest upon loans.

STOCKS, a wooden machine to put the legs of offenders in, for the securing of disorderly persons, and by way of punishment in divers cases ordained by statute, &c.

STOLE, GROOM OF THE, the eldest gentleman of his majesty's bed-chamber, whose office and honour it is to present and put on his majesty's first garment, or shirt, every morning, and to order the things into the chamber.

STONEHENGE, a stupendous monument, of Druidical antiquity, standing on Salisbury plain, and supposed to be nearly coeval with the pyramids of Egypt. Its origin and use are buried in impenetrable obscurity.

STONES and EARTHS. The only substances which enter into the composition of the simple stones, as far at least as analysis has discovered, are the six earths, silica, alumina, zirconia, glucina, lime, and magnesia; and the oxides of iron, manganese, nickel, chromium, and copper. Seldom more than four or five of these substances are found combined together in the same stone.

STONE-Ware. Under the denomination stone-ware are comprehended all the different artificial combinations of earthy bodies which are applied to useful purposes.

STOP, in Music, a word applied by violin and violincello performers, to that pressure of the strings by which they are brought into contact with the finger-board, and by which the pitch of the note is determined.

STOP, Trumpet, a reed metallic stop, so called because its tone is imitative of the trumpet.

STOPPER, of the Anchor, a strong rope attached to the cat-head, which, passing through the anchor-ring, is afterwards fastened to a timber-head, thereby securing the anchor on the bow. **Stoppers**, of the cables, commonly called deck-stoppers, have a large knot and a laniard at one end, and are fastened to a ring-bolt in the deck by the other; they are attached to the cable by the laniard, which is fastened securely round both by several turns passed behind the knot, or about the neck of the stopper, by which means the cable is restrained from running out of the ship when she rides at anchor. **Dog-Stoppers**, is a strong rope clenched round the main-mast, and used on particular occasions to relieve and assist the preceding when the ship rides in a heavy sea, or otherwise bears a great strain on the cable. **Wing-Stoppers**, similar pieces of rope clenched round one of the beams near the ship's side, and serving the same purpose as the preceding. **Stoppers** of the rigging, have a knot and a laniard at each end; they are used when the shrouds, stays, or back-stays, are out asunder in battle, or disabled in tempestuous weather, and are then lashed, in the same manner as those of the cables, to the separated parts of the shroud, &c. which are thereby reunited so as to be fit for immediate service. This, however, is only a temporary expedient, applied when there is not time or opportunity to refit them by a more complete operation. **Stoppers**, are also pieces of rope used to prevent the running rigging from coming up whilst being belayed.

STOPPERS, certain short pieces of rope, which are usually knotted at one or both ends, according to the purpose for which they are intended.

STORAX, in the Materia Medica, is the resinous drug which issues in a fluid state from incisions made in the bark or branches of the storax tree. It can be obtained in perfection only from those trees which grow in Asiatic Turkey.

STORE-KEEPER, an officer invested with the charge of the principal stores. **Store-Room**, an apartment or place of reserve, of which there are several in a ship, to contain the provisions or stores of a ship, together with those of her officers.

STORES, if any person who has the charge or custody of any of the king's armour, ordnance, ammunition, shot, powder, or habiliments of war, or of any victuals for victualling the navy, shall, to hinder his majesty's service, embezzle, purloin, or convey away the same to the value of 20s. or shall steal or embezzle any of his majesty's sails, cordage, or any other of his naval stores, to the value of 20s. he shall be adjudged guilty of felony, without benefit of clergy. 22 Car. II. c. 5.

STORK, a large bird of the heron class, of which many particulars are related that are remarkably singular. It is a

bird of passage. Egypt is said to be the place of its winter residence. It is in high repute among the Mahometans, approaching almost to veneration.

STORM, a term signifying a fall of snow, hail, or rain; also high wind, thunder, &c. In some places the term is restricted to high winds, thunder, &c.

STOVE, in Building, is a hot-house or room, but in a more restricted sense it is a place in which fires in dwelling-houses are made, and so contrived that it may communicate heat to the room, and send the smoke up the chimney. Stoves are of various constructions, and numerous patents have been taken out for inventions and improvements in what had been previously known. The great excellence of a stove consists in its adaptation to give the heat to the room, and to exclude the smoke. Towards these desirable objects many advances have been made, both by Englishmen and foreigners; but much yet remains to be done. See **FIRE-PLACE**.

STOVES, square boxes made of plank, and lined with brick, for burning charcoal in, to dress the admiral's victuals.

STOWAGE, the general disposition of the several materials contained in a ship's hold, with regard to their figure, magnitude, or solidity. In the stowage of different articles, as ballast, casks, cases, bales, or boxes, there are several general rules to be observed, according to the circumstances or qualities of those materials. The casks which contain any liquid are, according to the sea phrase, to be bung up and bilge free, that is, closely wedged up in an horizontal position, and resting on their quarters, so that their bilges (or where they measure most round) being entirely free, cannot rub against each other, or the ship's side, by the motion of the vessel. Dry goods, or such as may be damaged by the water, are to be carefully enclosed in casks, bales, cases, or wrappers, and wedged off from the bottom or sides of the ship, as well as from the bows, masts, and pump-well, &c. Due attention must likewise be had to their disposition, with regard to each other, and to the trim and centre of gravity of the ship, so that the heaviest may always be nearest the keel, and the lightest gradually above them.

STRAIT, a narrow channel or arm of the sea, contained between two opposite shores; as, the straits of Gibraltar, the straits of Sunda, the straits of Dover, &c.

STRAKES, or **STREAKS**, the uniform ranges of planks on the bottom or sides of a ship, or the continuation of planks joined to the end of each other, and reaching from the stern, which limits the vessel forward, to the stern-post and fashion-pieces, which terminate her length abaft. *Garboard-Streak*, is the lowest streak or range of planks, being let into rabbets in the keel below, and in the stem and stern-post at the ends. See the article **KEEL**.

STRAMONIUM, in Botany, *Datura*, Common Thornapple, is a powerful narcotic poison, and in many instances its deleterious effects have been attended with pernicious, and even fatal consequences. Some have fancied that smoking stramonium has proved beneficial in asthmatic complaints, and for shortness of breath.

STRAND, one of the twists or divisions of which a rope is composed. *Strand* also implies the sea-beach. *Stranded*, speaking of a cable or rope, signifies that one of its strands is broken. *Stranded*, applied to a vessel, means that she has run aground on the sea-shore, either by a tempest, or through bad steerage. Where any vessel is stranded, the justices of the peace are empowered to command the constables near the coast to call assistance, in order to preserve the ship, if possible.

STRAPADO, a barbarous military punishment, now abandoned. It consisted in having the hands of the offender tied behind his back, by which he was drawn to a certain elevation by a rope, then left to run suddenly towards the ground, when being stopped with a sudden jerk, his shoulders were dislocated. This was also one of the punishments of the inquisition, and perhaps it has been re-established with the restoration of that infernal tribunal.

STRATA, in Natural History, the several beds or layers of different matters, whereof the body of the earth is composed.

STRATAGEM, in War, a military wile or device for deceiving or deluding an enemy. The ancients were more expert in stratagems than the moderns, except the Indians of America, who in this art of circumvention are exceedingly dexterous.

STRAW, in Agriculture, the common name of the stem on which grain grew, and from which it is thrashed. A considerable portion is used as fodder, for various other purposes, and finally as manure.

STREAKY CHEESE, in rural economy, is made from a mixture of new and old curd, or of two sorts which have different proportions of colouring in them, giving a variegated appearance, and hence the name.

STREAM TIN, in Mineralogy, consists of particles or masses of tin ore, found beneath the surface in alluvial grounds, generally in low situations. Its name is derived from the streams of water used to separate the earthy matter from it. This ore is of the best quality, and is occasionally mixed with small particles of gold. *Stream Works*, are the usual repositories in which the stream tin is found. *Streaming*, denotes the management of a stream work, or of stream tin during the process of refinement.

STRENGTH. All experiments made on the strength of materials, when well conducted, are highly valuable, in as much as they lie at the very foundation of mechanical science, as applied to practice. Those acquainted with the history of mechanics, cannot be ignorant that many machines, otherwise well contrived, have been found quite inadequate to their proposed ends; some of them not having strength enough, in different parts, to bear the pressure of the rest; and others, on the contrary, so loaded with unnecessary matter as to be ready to fall to pieces by their own weight. The same remark is applicable to architectural structures, many of which have given way only from a want of due proportion in the strength and weight of the different parts. And we add, that the value of such experiments is greatly increased, by having the manner in which they were conducted, (as in the present instance,) laid before the public; as any error in applying the means employed, or in deducing the inferences, is thus avoided; or, if any have been committed, may be detected. We purpose, therefore, in the first place in this article, to lay before our readers some experiments made by George Rennie, Esq. civil engineer, and which were first published in the Philosophical Transactions for 1818. The notes with which the article is accompanied, add not a little to its value, being by Mr. Thomas Tredgold, to whom the public is indebted for several valuable practical works, possessing considerable merit, and highly useful to mechanics and builders. The notes were first given to the world in the late Dr. Tilloch's Magazine for 1819.

Preliminary Remarks.—The knowledge of the properties of bodies which come more immediately under our observation, is so instrumental to the progress of science, that any approximation to it deserves our serious attention. The passage over a deep and rapid river, the construction of a great and noble edifice, or the combination of a more complicated piece of mechanism, are arts so peculiarly subservient to the application of these principles, that we cannot be said to proceed with safety and certainty, until we have assigned their just limits. The vague results on which the more refined calculations of many of the most eminent writers are founded, have given rise to such a multiplicity of contradictory conclusions, that it is difficult to choose, or distinguish the real from that which is merely specious. The connexions are frequently so distant, that little reliance can be placed on them. The Royal Society appears to have instituted, at an early period, some experiments on this subject, but they have recorded little to aid us. Emerson, in his *Mechanics*, has laid down a number of rules and approximations. Professor Robinson, in his excellent treatise in the *Encyclopædia Britannica*; Banks on the *Power of Machines*; Dr. Anderson, of Glasgow; Colonel Bcaufoy, &c. are those, amongst our countrymen, who have given the result of their experiments on wood and iron. The subject, however, appears to have excited considerable attention on the continent. A theory was published in the year 1638, by Galileo, on the resistance of solids, and subsequently by many other philosophers. But however plausible these investigations appeared, they were more theoretical than practical, as will be seen in the sequel. It is only by deriving a theory from careful and well-directed experiments, that practical results can be obtained. It would be useless to enumerate the labours of those philosophers, who in following, or varying from, the steps

of Galileo, have merely tended to obscure a subject, respecting which they had no data to proceed upon. It is sufficient to enumerate the names of those who, in conjunction with our own countrymen, have added their labours to the little knowledge we possess. The experiments of Buffon, recorded in the *Annals of the Academy of Sciences at Paris*, in the years 1740 and 1741, were on a scale sufficiently large to justify every conclusion, had he not omitted to ascertain the direct and absolute strength of the timber employed. It, however, appeared from his experiments, that the strength of the ligneous fibre is nearly in proportion to the specific gravity. Muschenbroeck, whose accuracy (it is said) entitled him to confidence, made a number of experiments on wood and iron, which, by being tried on various specimens of the same materials, afforded a mean result considerably higher than any other previous authorities. Experiments have also been made by Mariotte, Varignon, Perronet, Ramus, Rondelet, Gauthey, Navier, Aubry, and Texier de Norbeck, as also at the *Ecole Polytechnique*, under the direction of M. Prony. With such authorities before us, it might be deemed presumption in me, to offer a communication on a subject which had been previously treated of by so many able men.* But whoever has had occasion to investigate the principles upon which any edifice is constructed, where the combination of its parts is more the result of uncertain rules than sound principle, will soon find how scanty is our knowledge on a subject so highly important. The desire of obtaining some approximation, which could only be accomplished by repeated trials on the substances themselves, induced me to undertake the following experiments.

Description of the Apparatus. (See the Plate.)—A bar of the best English iron, about ten feet long, was selected, and formed into a lever (whose fulcrum is denoted by *f*). The hole was accurately bored, and the pin turned, which suffered it to move freely. The standard *A* was firmly secured by the nut *c* to a strong bed-plate of cast iron, made firm to the ground. The lever was accurately divided in its lower edge, which was made straight in a line with the fulcrum. A point, or division, *D*, was selected, at five inches from the fulcrum, at which place was let in a piece of hardened steel. The lever was balanced by the balance weight *E*, and in this state it was ready for operation. But in order to keep it as level as possible, a hole was drilled through a projection on the bed-plate, large enough to admit a stout bolt easily through it, which again was prevented from turning in the hole by means of a tongue *t*, fitting into a corresponding groove in the hole. So that, in order to preserve the level, we had only to move the nut to elevate or depress the bolt, according to the size of the specimen. But as an inequality of pressure would still arise from the nature of the apparatus, the body to be examined was placed between two pieces of steel, the pressure being communicated through the medium of two pieces of thick leather above and below the steel pieces, by which means a more equal contact of surfaces was attained.† The scale was hung on a loop of iron, touching the lever in an edge only. I at first used a rope for the balance-weight, which indicated a friction of four pounds, but a chain diminished the friction one half. Every moveable centre was well oiled. Of the resistances opposed to the simple strains which may disturb the quiescent state of a body, the principal are the repulsive force, whereby it resists compression, and the force of cohesion, whereby it resists extension. On the former,

with the exception of the experiments of Gauthey and Rondelet on stones, and a few others on soft substances, there is scarcely any thing on record. In the memoir of M. Lagrange, on the force of springs, published in the year 1760, the moment of elasticity is represented by a constant quantity, without indicating the relation of this value to the size of the spring: but in the memoir of the year 1770, on the forms of columns, where he considers a body whose dimensions and thickness are variable, he makes the moment of elasticity proportional to the fourth power of the radius, in observing the relations of theory and practice to accord with each other. This was admitted by Euler in his memoir of 1780, in his elaborate investigation of the forms of columns. Mr. Coulomb had, however, shewn before that time, how inapplicable all these calculations were to columns under common circumstances; and similar observations have been made in subsequent lectures on natural philosophy. The results of experiments have also been equally discordant; since it is deduced from those of Reynolds, that the power required to crush a cubic quarter of an inch of cast iron is 448000 lbs. avoirdupois, or 200 tons; whereas by the average of thirteen experiments made by me on cubes of the same size, the amount never exceeded 10392.53 lbs. not quite five tons; This may be seen by referring to the tables. There were four kinds of iron used, viz. 1st. Iron taken from the centre of a large block, whose crystals were similar in appearance and magnitude to those evinced in the fracture of what is usually termed gun-metal. 2dly. Iron taken from a small casting, close-grained, and of a dull gray colour. 3dly. Iron cast horizontally in bars of $\frac{1}{2}$ inches square, 8 inches long. 4thly. Iron cast vertically, same size as last. These castings were reduced equally on every side to $\frac{1}{4}$ of an inch square: thus removing the hard external coat usually surrounding metal castings. They were all subjected to a gauge. The bars were then presumed to be tolerably uniform. The weights used were of the best kind that could be procured, and as the experiment advanced, smaller weights were used.

Experiments on Cast-Iron in Cubes of $\frac{1}{4}$ of an Inch, &c.—Iron taken from the block whose specific gravity was 7.033.

Averages.	lbs. avoirdupois.
1439.66	$\left\{ \begin{array}{l} \frac{1}{4} \times \frac{1}{4} \dots\dots\dots 1454 \\ \frac{1}{4} \times \frac{1}{4} \dots\dots\dots 1416 \\ \frac{1}{4} \times \frac{1}{4} \dots\dots\dots 1449 \end{array} \right.$

On specimens of different lengths. Specific gravity of iron 6.977.

2116	$\left\{ \begin{array}{l} \frac{1}{4} \times \frac{1}{4} \dots\dots\dots 1922 \\ \frac{1}{4} \times \frac{1}{4} \dots\dots\dots 2310 \end{array} \right.$
	$\left\{ \begin{array}{l} \frac{1}{4} \times \frac{1}{4} \text{ slipped with 1863 lbs. filed flat, and} \\ \text{crushed with} \dots\dots\dots 2363 \\ \frac{1}{4} \times \frac{1}{4} \text{ ditto, } \dots\dots 1495, \text{ ditto} \dots\dots 2005 \\ \frac{1}{4} \times \frac{1}{4} \text{ ditto, } \dots\dots\dots 1407 \\ \frac{1}{4} \times \frac{1}{4} \text{ ditto, } \dots\dots\dots 1743 \\ \frac{1}{4} \times \frac{1}{4} \text{ ditto, } \dots\dots\dots 1504 \\ \frac{1}{4} \times \frac{1}{4} \text{ ditto, } \dots\dots\dots 1459 \end{array} \right.$

April 23, 1817. *Experiments on Cubes of $\frac{1}{4}$ of an Inch, taken from the Block.*

9773.5	$\left\{ \begin{array}{l} \frac{1}{4} \times \frac{1}{4} \dots\dots\dots 10561 \\ \frac{1}{4} \times \frac{1}{4} \dots\dots\dots 9506 \\ \frac{1}{4} \times \frac{1}{4} \dots\dots\dots 9917 \\ \frac{1}{4} \times \frac{1}{4} \dots\dots\dots 9250 \end{array} \right.$
--------	--

* It is true that the subject has been considered by many able philosophers, from Galileo down to the present period; but it is only lately that the proper object of attention has been ascertained; or at least the results of their inquiries had not been brought forward in a practicable form. For when Dr. T. Young published his Lectures, there was little on the subject besides the intricate, and I may add unsatisfactory, investigations of Euler and Lagrange. As to the resistance to fracture, which with the greater part of mechanical writers is the only object attended to, it is of very inferior importance.—The laws of flexure constitute the chief guide in the construction of buildings: and the intention of these notes is to call the attention of experimentalists to this part of the subject: and as it is probable the ingenious author of the experiments now before me may be tempted to resume his labours, I feel certain that he will not feel displeased to have his attention called to some interesting points of inquiry, which he has either omitted to notice, or has not given to the public.—T. T.

† This machine must have had a considerable degree of friction, and Mr. Rennie has not, apparently, attempted to determine the quantity: it must however have been very great in the high pressures. The lever turned upon a pin similar to that used by Gauthey, (Rozier's *Journal de Physique*, tome iv. p. 403,) which Perronet found to have much friction, and to cause great irregularity. To remedy the defects of this machine, another was contrived by Rondelet, in which he attempted, and it appears successfully, to obviate the most material defects of the old one. The action was more equal on the compressed surface, and a more accurate measure of the strength was obtained. Rondelet's machine is described in his *Traité Théorique et Pratique de l'Art de Bâtir*, tome iii. p. 79.—T. T.

‡ It is probable that Mr. Reynolds made his experiments on metal cast at the furnace of Maidley Wood, which is of a very strong and superior quality; but this circumstance can have been but of little importance compared to the great disproportion of the results.—T. T.

$\frac{1}{2} \times \frac{1}{2}$ wrought copper, $\frac{1}{4}$ 3427 $\frac{1}{2}$	6440
$\frac{1}{2} \times \frac{1}{2}$ cast tin, $\frac{1}{4}$ 552 $\frac{1}{2}$	966
$\frac{1}{2} \times \frac{1}{2}$ cast lead, $\frac{1}{4}$	483

The anomaly between the three first experiments on $\frac{1}{2}$ cubes, and the two second of a different length, can only be accounted for, on the difficulty of reducing such small specimens to an equality. The experiments on $\frac{1}{2}$ inch prisms of different lengths give no ratio. The experiments on $\frac{1}{2}$ inch cubes, taking an average of the three first in each, give a proportion between them and the three on $\frac{1}{2}$ cubes,

as 1 : 6.036 in the block castings
as 1 : 7.352 in the horizontal ditto,
as 1 : 8.035 in the vertical ditto,

in several cases the proportion is as the cubes.—The vertical cube castings are stronger than the horizontal cube castings.—The prisms usually assumed a curve similar to a curve of the

* In these experiments, the results are so irregular, that no practical conclusions can be derived from them. There are many circumstances that affect the results of such experiments, which were observed by Gauthey; such as the position of the specimen, the form of its surfaces, and the inequality of the different specimens—which were so extremely small, that it would be scarcely possible to obtain any tolerable degree of accuracy.

Gauthey's experiments exhibit a like irregularity, indicating no relation between the height of the piece and its resistance, (Rozier's *Journal*, tome iv. p. 407.) It appears probable that when the fracture is of that kind where the body decomposes into pyramids, the length does not influence the result, provided that the piece be long enough to admit of the free motion of the fractured parts. I imagine that hard cast iron breaks into pyramids, but the nature of the fracture Mr Rennie has not stated. Probably it was so soft as to break in the manner of flexible bodies, in which, though the forces must act according to some regular law, it is difficult to trace their operation in a continuous solid.—T. T.

† The degree of compression of these bodies having been observed, we might conclude that the height of the modulus of elasticity might be obtained from these experiments. This, however, is not the case; and so far proves that the strain is not of that simple kind which it has been supposed to be. The reduction of length might be easily measured, even in hard bodies, by an apparatus for multiplying its extent; and it would throw much

light on the subject, to reduce pieces of the same length but of different areas to a given length. Such a set of experiments would be infinitely more valuable than those on the fracture, and much more easily made, as the apparatus would be easier to manage.

Experiments on the Suspension of Bars.—The lever was used as in the former case, but the metals were held by nippers, as indicated in the drawing No. 2. They were made of wrought iron, and their ends adapted to receive the bars, which, by being tapered at both extremities, and increasing in diameter from the actual section, (if I may so express it,) and the jaws of the nippers being confined by a hoop, confined both. The bars, which were six inches long, and $\frac{1}{2}$ square, were thus fairly and firmly grasped.

April 30, 1817

No.	lbs.
45 $\frac{1}{2}$ inch, cast-iron bar, horizontal	1166
46 $\frac{1}{2}$ do. do. vertical	1218
47 $\frac{1}{2}$ do. cast steel previously tilted	8391
48 $\frac{1}{2}$ do. blister steel, reduced per hammer	8322
49 $\frac{1}{2}$ do. shear steel, do. do.	7977
50 $\frac{1}{2}$ do. Swedish iron, do. do.	4504
51 $\frac{1}{2}$ do. English iron, do. do.	3492
52 $\frac{1}{2}$ do. hard gun-metal, mean of two trials	2273
53 $\frac{1}{2}$ do. wrought copper reduced per hammer	2112
54 $\frac{1}{2}$ do. cast copper	1192
55 $\frac{1}{2}$ do. fine yellow brass	1123
56 $\frac{1}{2}$ do. cast tin	296
57 $\frac{1}{2}$ do. cast lead	114

Remarks on the last Experiments.—The ratio of the repulsion of the horizontal cast cubes to the cohesion of horizontal cast bars, is 8.65 : 1. The ratio of the vertical cast cubes to the cohesion of the vertical cast bars, is as 9.14 : 1. The average of the bars, compared with the cube, No. 16, is as 10.611 : 1. The other metals decrease in strength, from cast steel to cast lead.

The stretching of all the wrought bars indicated heat.* The fracture of the cast bars was attended with very little diminution of section, scarcely sensible.

The experiment made by M. Prony, (which asserts, that, by making a slight incision with the file, the resistance is diminished one half,) was tried on a $\frac{1}{2}$ inch bar of English iron; the result was 2920 lbs., not a sixth part less. This single experiment, however, does not sufficiently disprove the authority of that able philosopher, for an incision is but a vague term. The incision I made might be about the 40th part of an inch.

Experiments on the Twist of $\frac{1}{2}$ Inch Bars.—To effect the operation of twisting off a bar, another apparatus was prepared: it consisted of a wrought-iron lever two feet long, having an arched head about 1-6th of a circle, of four feet diameter, of which the lever represented the radius, the centre round which it moved had a square hole made to receive the end of the bar to be twisted. The lever was balanced as before, and a scale hung on the arched head; the other end of the bar being fixed

light on the subject, to reduce pieces of the same length but of different areas to a given length. Such a set of experiments would be infinitely more valuable than those on the fracture, and much more easily made, as the apparatus would be easier to manage.

The importance of the laws of stiffness over those of strength has been ably stated by Dr. Young, (Lectures on Natural Philosophy, vol. i.) and what he has stated in favour of stiffness applies equally to the mode of experimenting I now recommend, which could not fail of establishing some important practical rules.—T. T.

† Mr. Rennie's apparatus did not permit of measuring the extension of the specimens. In some experiments made by Mr. Telford, (Barlow's Essay on the Strength of Timber, &c. p. 230,) where the extension was measured, it appears to have been greatest at the middle of the length, and to increase from the ends towards the middle in a ratio sensibly proportional to the square of the distance from the end. This fact is at variance with the received opinion respecting the strain.

Dr. Thomson has remarked, (Annals of Philosophy, vol. xii. p. 450,) that the strengths of English and Swedish iron are not in the same proportion as is found by comparing Count Stokengen's with that described in the Annals for April 1816. But if I do not mistake, Stokengen's was made on wire, and consequently would be higher, as the strength is always much increased by forging, wire-drawing, &c.—T. T.

in a square hole in a piece of iron, and that again in a vice. The undermentioned weights represent the quantity of weight put into the scale.

Remarks.—Here the strength of the vertical bars still predominates. The average of the two taken conjointly, and compared with a similar case of $\frac{1}{2}$ inch bars, gives the ratio as the

* In the resistance to twisting, there are some doubts by different writers expressed respecting the effect of the length: these experiments, however, do not appear calculated to remove them; they are so extremely irregular. The angle of torsion was not observed, though it certainly would not have been difficult to have done so in the longer pieces. Some experiments on larger specimens are described in Thomson's Annals for March 1819; but we cannot compare them with these, for want of a more correct knowledge of the nature of this strain.—T. T.

† These experiments are merely a repetition of those in a preceding page, experiments 64 to 73; except that here cast steel is stated to be 19 lbs. 9oz. instead of 17lbs. 9oz.

‡ The experiments on wood are considerably below those of other writers; and it appears singular that the four-inch specimen should be stronger than the shorter length. According to Rondelet's experiments to crush a cubic inch of oak it required from 5000 to 6000lbs. avoirdupois.

of fir - from 6000 to 7000lbs.

cubes, as was anticipated. In the horizontal castings of different lengths, the balance is in favour of the increased lengths; but in the vertical castings, it is the reverse. In neither is there any apparent ratio. In the horizontal castings at 6 inches from the bearing, there is a visible increase, but not so great as when close to the bearing.

134 Aberdeen granite, blue kind	2.625	24556

In the former the pieces were compressed 1-3d of their length; in the latter one half of their length (Rondelet's *L'Art de Bâtir*, tome iv. p. 67.) Mr. Rennie has not stated the diminution of length.—T. T.

§ It certainly would have been preferable to have placed a hard and rigid substance next the stone, in order to secure equality of pressure.—T. T.

|| Gauthey tried the stones in different positions in respect to their natural beds; but from a general view of his experiments, it does not appear that he was correct in concluding them to be stronger when "posées en défil," because his comparison is made between means that include sections of very different forms. (Rozer's *Journ.* tome iv. p. 496.)—T. T.

¶ According to Gauthey's experiments, a cubic inch of brick, specific gravity 1.557, was crushed by 1562 lbs. avoirdupois of Flanders marble 2.628 13143 of Genoese do. 2.700 4856 of porphyry 2.871 25568—T. T.

N. B. The specific gravities were taken with a delicate balance, made by Creighton of Glasgow; all with the exception of two specimens, which were by accident omitted.*

Remarks.—In observing the results presented by the preceding table, it will be seen that little dependence can be placed on the specific gravities of stones, so far as regards their repulsive powers, although the increase is certainly in favour of their specific gravities. But there would appear to be some undefined law in the connexion of bodies, with which the specific gravity has little to do. Thus, statuary marble has a specific gravity above Aberdeen granite, yet a repulsive power not much above half the latter. Again, hardness is not altogether a characteristic of strength, inasmuch as the limestones, which yield readily to the scratch, have nevertheless a repulsive power approaching to granite itself.†

It is a curious fact in the rupture of amorphous stones, that pyramids are formed, having for their base the upper side of the cube next the lever, the action of which displaces the sides of the cubes, precisely as if a wedge had operated between them. I have preserved a number of the specimens, the sides of which, if continued, might cut the cubes in the direction of their diagonals.

* Mr. Rennie has, of course, taken the specific gravity in the usual manner, but certainly not the real specific gravity of the stone in any of the porous ones, though it may be that of the material the stone is composed of. When a stone is porous—and many building stones are very much so—it will be found that the specific gravity, as usually obtained, is not the weight of a cubic foot in ounces avoirdupois, which it certainly ought to be, and particularly where the information is intended for the use of practical men. If Mr. Rennie were to try any of his specimens, he would find the weight of a cubic foot much below the numbers he has given in the case of brick, coillite, and sandstones. The specific gravity of a minute concretion of Portland stone may be 2.432, or, as Kirwan has it, 2.461, but that of the stone itself is much lower.

Were the real specific gravity of porous stones taken, their comparative heaviness would become a more decisive mineral character than it is according to the present method, and the correction presents no difficulty.—T. T.

† A curious circumstance was observed by Rondelet in his experiments; viz. that the blocks from the middle of a stratum of stone were of a higher specific gravity than those taken either from the upper or lower part of the stratum. The stones were from Châtillon, Bagnoux, &c. He also observed, that in the same kind of stone the strength was as the cube of the specific gravity. (*L'Art de Bâtir*, tome iii. p. 83, *et suiv.*) That any relation should exist between the specific gravity and strength of stones of different kinds was not to be expected, as strength depends on other properties.—T. T.

‡ It is in these experiments that we have most to regret the want of observations, and those of a nature that would have added little to the labour which all, who make such experiments, must undergo. It is, however, a labour that is, to a mind engaged in the search of knowledge, more pleasing than those unaccustomed to such feelings, can conceive. But too often it is a pleasure that cannot be pursued, except at an expense and encroachment on the hours of business which a professional man can ill afford to indulge in. The defect of these experiments consists in the want of observations on the flexure produced by given weights, particularly in the first degrees of deflexion; and it is the more to be regretted, because we have very few experiments on cast-iron, where such observations have been made. Banks states, that his specimens bent about an inch at the time of fracture; and

160 A feather-edged or $\frac{1}{2}$ bar, whose dimensions were 151 $\frac{1}{2}$ inches deep by 2 wide 10 0 edge up 2 8 3106

155 An inch square bar bore	280
156 A bar 2 inches deep, by $\frac{1}{2}$ an inch thick	539
157 An inch bar, the ends made fast	1173

The paradoxical experiment of Emerson was tried which states that by cutting off a portion of an equilateral triangle, (see page 114 of Emerson's *Mechanics*.) the bar is stronger than before, that is, a part stronger than the whole! The ends were loose at 2 feet 8 inches apart as before. The edge from which the part was intercepted was lowermost, the weight was applied on the base above, it broke with 1129 lbs. whereas in the other case it bore only 840 lbs.

Remarks on the Transverse Strain.—Banks makes his bar from the cupola, when placed on bearings 3 feet asunder, and the ends loose, to bear

Now, all my bars were cast from the cupola, the difference was therefore

I adopted a space of 2 feet 8 inches asunder, as being more convenient for my apparatus. The strength of the different bars, all cases being the same, approaches nearly to the theory which makes the comparative values as the breadths multiplied into the squares of the depths. The halves of the bars were tried merely to keep up the analogy. The bar of 4 inches deep, however, falls short of theory by 365 lbs. It is evident we cannot extend the system of deepening the bar much further, nor does the theory exactly maintain in the case of the equilateral triangle by

Dr. Young has calculated the height of the modulus of elasticity from this statement, (*Nat. Phil.* vol. ii. art. 328.) but it is well known, that the deflexion is not regular when the piece is nearly broken. In Banks's experiments on curved bars, the deflexion is given, but the thickness of the bars is not stated. It is true, Rondelet has made some experiments on cast-iron, where the successive deflexions were registered, but these experiments are not very regular; besides, it would be desirable to have experiments on British iron.

As I have two experiments by me, I shall take this opportunity of laying them before my readers. A bar of cast-iron, from a Welsh foundry, which did not yield easily to the file, was laid upon supports exactly three feet apart; the bar was an inch square, and when 308 lbs. were put into a scale suspended from the middle of its length, the deflexion was found to be $\frac{3}{16}$ ths of an inch; whence the height of the modulus of elasticity is 6,396,688 feet. The experiment was made by Mr. R. Ebbels, at Germes, near Hereford. A joint of cast-iron 9 inches deep, resembling in form the letter I, was laid upon supports 19 feet apart, first on its edge, when the deflexion from its own weight was $\frac{3}{4}$ ths of an inch. It was then laid flatwise, and the deflexion from its own weight was $3\frac{1}{2}$ inches. The castings were from Messrs. Dawson's foundry, Edgeware Road. The iron yielded easily to the file. The height of the modulus of elasticity, according to the experiment on the joint flatwise, is

— on the edge is

The deflexion being very small when the joint was on its edge, perhaps it was not measured with the necessary degrees of accuracy, as a very small error would cause the difference in the result. The following table contains the value of the modulus for cast-iron, according to the experiments above stated.

Height of Modulus in feet. Experimenters.	
Cast-iron (Welsh)	6,396,688 Ebbels.
Cast-iron	5,500,000 Banks.
Cast-iron, grey French	5,093,450 Rondelet.*
Cast-iron, soft do.	4,317,000 Rondelet.*
Cast-iron	5,700,000 By my trial.—T. T.

* *L'Art de Bâtir*, tome iv. part ii. p. 514.

The diagonal position of the square bar is actually worse than when laid on its side, contrary to many assertions.* The same quantity of metal in the feather-edged bars was not so strong as in the 4-inch bar.

The semi-elliptic bar exceeded the 4-inch bar, although taken out of it. The parabolic bar came near it. The bar made fast at both ends, I suspect must have yielded, although the ends were made fast by iron straps. The experiments from Emerson on solids of different forms might be made; but the time and trouble these experiments have already cost, have compelled me to relinquish further pursuits for the present. If, however, in the absence of better, they are worthy of the indulgence of the Royal Society, it will not only be a consolation to me that my labours merit their attention, but a further inducement to prosecute the investigation of useful facts, which even in the present advanced state of knowledge will yet admit of addition.

It has been observed by professor Leslie, that the strength of materials is exerted in four different ways: 1. In sustaining a longitudinal tension; 2. In withstanding a longitudinal compression; 3. In resisting a transverse pressure; and, 4. In opposing the act of twisting or wrenching.

1. *Longitudinal Tension.*—The tension which a stone pillar, a bar of metal, a beam of wood, or even a hempen rope, can bear when pulled lengthwise, must evidently depend upon the cohesion of any cross section. As the material stretches out, the longitudinal attraction of the particles becomes augmented. This increase, at first, is proportional to the dilatation, but it afterwards advances very slowly, and a small additional strain is then sufficient to produce that limit of extension which occasions total fracture or disruption of the column. Its length will nowise affect the utmost strain which it can bear, this being determined merely by the smallest cross section where the dislocation of the particles will take place.

Let Z A be a prism stretched in the direction of its length. The particles of the section B will be pulled from those of the section C, till an attraction be generated equal to the whole tension. But the particles of the section C, must settle in equilibrium, and are consequently drawn back by an equal force. In this acquired position, therefore, they must attract the particles of the section D with the same force. The original tension is thus transferred successively to the extremity Z, where it is finally exerted, the effect of its action being neutralized in all the intermediate sections.

The cohesive power thus evolved, is hence the accumulative attraction of all the particles in any sec-

* That a square bar was weakest in the direction of its diagonal, I had from theory determined some time ago, and the investigation is given in the Phil. Mag. vol. L. p. 418; and it is very satisfactory to find it confirmed by these experiments, and also by those of Mr. Barlow.

It is not an easy task to make accurate experiments on triangular bars, as it is difficult to protect the angle, unless a kind of saddle be used, which must affect the result.—T. T.

† The science of construction is yet in its infancy, and certainly requires many additions. The first experiments on the strength of materials appear to have been made before the Royal Society; and there can be no doubt that a favourable reception will be given to any others that will tend to elucidate a subject, which is likely to form one of the principal branches of an engineer's education: as he must either proceed on the principle of science, or be directed by a feeling of fitness, which is to be acquired only by devoting a life-time to the practice of his art. It is to be hoped that Mr. Reame will speedily bring forward some additions to the valuable experiments he has already made, with more detailed descriptions of the phenomena observed in the course of his labours. The example of the chemists ought to be followed, as it is not the number but the accuracy and correct description of experiments that constitute their value. Mr. Barlow has represented some of the fractures in his experiments by engravings, which is certainly an excellent plan.

In Evelyn's *Sylva*, (Dr. Hunter's edition, vol. ii. p. 227.) it is stated, that a treatise on duplicate proportion was published by Sir William Petty, in which is "A new hypothesis of elastic or springy bodies, to shew the strengths of timbers, and other homogeneous materials, applied to buildings, machines, &c." I have never been able to procure the work; but if any of your correspondents could furnish a sketch of this "new hypothesis," it would be a desirable addition to the history of this branch of science; as, if it should accord with Evelyn's description, our countryman will rank amongst the first contributors to the resistance of solids.—T. T.

tion. The corresponding longitudinal distention is at first proportional to it, but afterwards increases in a more rapid progression. Thus, a bar of soft iron is found to stretch uniformly, by continuing to append to it equal weights, till it be loaded with half as much as it can bear; beyond that limit, however, its extension will be doubled by each addition of the eighth part of the disruptive force. Supposing the bar to be an inch square and 1000 inches in length, 38,000 lbs. avoirdupois would draw it out 1 inch; but 45,000 lb. would stretch it 2 inches; 54,000 lb. 4 inches; 63,000 lb. 8 inches; and 72,000 lb. 16 inches; when it would finally break, the extension being now eight times greater than its ordinary rate.

Let A B in the annexed figure be a prism or bar of any material, and its prolongation B C express the whole longitudinal force exerted, which occasions the small extension A a. While the length of this bar B C continues the same, it is evident that a A must be proportional to the distaining weight B C. Make, therefore, a A : B C :: A B : C D; or, alternately, a A : A B :: B C : C D, and C D must be constant. Since B C now bears the same relation to C D as a A to A B, any portion of C D will, by its weight, produce a corresponding distention of A B. Thus a column of the thousandth part of the length of C D would extend A B one thousand part, and the same weight would, by its compression, occasion an equal contraction. The column C D thus found is called the *Modulus of Elasticity*; it depends entirely on the nature of the cohesive substance, and may be determined by a single experiment.

Of the principal kinds of timber employed in building and carpentry, the annexed table will exhibit their respective modulus of elasticity, and the portion of it which limits their cohesion, or which lengthwise would tear them asunder.

Teak,	6,040,000 feet,	168th.
Oak,	4,150,000 feet,	144th.
Sycamore,	3,860,000 feet,	108th.
Beech,	4,180,000 feet,	107th.
Ash,	4,617,000 feet,	106th.
Elm,	5,680,000 feet,	140th.
Memel Fir,	8,292,000 feet,	205th.
Christiana Deal,	8,118,000 feet,	140th.
Larch,	5,096,000 feet,	121st.

A tabular view may likewise be given of their absolute cohesion, or the load which would rend a prism of an inch square, and the altitude of the prism which would be covered by the action of its own weight.

Teak,	12,915 lb.	36,049 feet.
Oak,	11,880 lb.	32,900 feet.
Sycamore,	9,630 lb.	35,800 feet.
Beech,	12,225 lb.	38,940 feet.
Ash,	14,130 lb.	42,080 feet.
Elm,	9,720 lb.	39,050 feet.
Memel Fir,	9,540 lb.	40,500 feet.
Christiana Deal,	12,346 lb.	55,500 feet.
Larch,	12,240 lb.	42,160 feet.

It is singular, that woods of such diversified structure should yet differ so little on the whole in their elasticity and cohesion. Specimens of the same sort will occur, which are sometimes as much varied as the several kinds themselves. The modulus of the elasticity of hempen fibres has not been ascertained, but may probably be reckoned about 5,000,000 feet. Their cohesion is, for every square inch of transverse section, 6,400 lb. The usual mode of estimating the strength of a cable or rope of hemp, is to divide by five the square of its number of inches in girth, and the quotient will express in tons the utmost strain it could bear. But the computation is rather simpler, to double the square of the diameter of the rope. This estimate, however, applies only to new ropes formed of the best materials, not much twisted, and having their strands laid even. If yarn of 180 yards long be worked up into a rope of only 120 yards, it will lose one-fourth of its strength, the exterior fibres alone resisting the greatest part of the strain. The register cordage of the late Captain Huddart exerts nearly the whole force of the strands, since they suffer a contraction of only the eighth part in the process of combining.

The metals differ more widely from each other in their elastic

force and cohesive strength, than the several species of wood or vegetable fibres. Thus the cohesion of fine steel is about 135,000 lb. for the square inch, while that of cast lead amounts only to about the hundred and thirtieth part, or 1800 lb.

According to the very accurate experiments of George Rennie in 1817, and already noticed, the cohesive power of a rod an inch square, of different metals, in pounds avoirdupois, with the corresponding length in feet, is as follows :

Cast Steel,.....	134,256 lb.	39,455 feet.
Swedish Malleable Iron, 72,064 lb.		19,740 feet.
English ditto,	55,872 lb.	16,938 feet.
Cast Iron,	19,036 lb.	6,110 feet.
Cast Copper,.....	19,072 lb.	5,003 feet.
Yellow Brass,	17,958 lb.	5,180 feet.
Cast Tin,	4,736 lb.	1,496 feet.
Cast Lead,.....	1,824 lb.	348 feet.

It thus appears, that a vertical rod of lead, 348 feet long, would be rent asunder by its own weight. The best steel has nearly twice the strength of English soft iron, and this again is about three times stronger than cast iron. Copper and brass have almost the same cohesion as cast iron.

2. Longitudinal Compression.—The compression which any column suffers is at first equal to the dilatation occasioned by an equal and opposite strain, being in both cases proportional to the modulus of elasticity. But while the incumbent weight is increased, the power of resistance likewise augments, as long as the column withstands inflexure. After it begins to bend, a lateral disruption soon takes place. A slender vertical prism is hence capable of supporting less pressure than the tension which it can bear. Thus a cube of English oak was crushed only by the load of 3860 lb. but a bar of an inch square and 5 inches high gave way under the weight of 2572 lb. It would evidently have been still feebler if it had been longer. On the other hand, if the breadth of a column be considerable in proportion to its height, it will sustain a greater pressure than its cohesive power. Thus, though the cohesion of a rod of cast iron of the quarter of an inch square is only 300 lb., a cube of that dimensions will require 1440 lb. to crush it.

In general, while the resisting mass preserves its erect form, the several sections are compressed and extended by additional weight, and their repellent particles are not only brought nearer, but multiplied. This repulsion is likewise increased by the lateral action arising from the confined ring of detrusion. The primary resistance becomes hence greatly augmented in the progress of loading the pillar.

3. Transverse or Lateral Pressure.

— Suppose the beam AB (in the annexed figure) to have one end firmly implanted in a wall GH, and a vertical pressure applied at the other end. This beam, sinking under the load at B, may be conceived to turn on the lowest point at A as a fulcrum; consequently the particles of the vertical section AC will be forced into the oblique position AD, each of them being turned aside through a space proportional to its distance from A. The strain exerted at the end AC will therefore be the result of the aggregate dislocations of all the particles of the section. When the breadth and length of the beam remain the same, this accumulate strain must evidently be proportional to the area of the triangle CAD, and consequently to the square of the depth AC. But when the breadth of the beam is taken likewise into account, the triangle of tension becomes converted into a wedge, and the strain hence follows the direct ratio of that breadth. Omitting the weight of the beam, and assuming its depth and breadth as constant, the tension of any particle at C may be considered as acting against the short arm AC of the rectangular beam CAB, and withstanding the load suspended at B. The weight thus resisted by the cohesion of the beam, is therefore inversely as the length AB. Combining all these circumstances, we conclude, that the strength of a beam firmly inserted in a

wall, or its power to resist a pressure at its remote extremity, is compounded of the direct ratios of its breadth, and of the square of its depth, and the inverse ratio of its length. Thus, a beam having the same length and breadth as another, but twice the depth, is four times stronger; and a beam of the same depth and breadth, and double the length, is only half so strong. Hence also, a beam, whose depth is triple its width, will sustain a load three times greater. For the same reason, a square prism will have its strength inversely as its length and the cube of its thickness. In general, the resistance of a beam of any form, but of a given length, to a cross strain, will be the same as if the whole power exerted were collected in the centre of gravity of each section. Thus, the strain of a triangular prism may be conceived as concentrated in a point at one-third of the distance of the perpendicular from the vertex to the base. Such a prism is therefore twice as strong set on its edge as when laid on its side. This simple investigation we owe to Galileo, and, though partly hypothetical, it is a near approximation to the truth. It is of essential service in improving the practice of carpentry, and sheds a clear light over the economy of nature in the structure of animals and vegetables. Reeds and herbaceous plants derive their power of resisting the wind, from the subdivision of their length into moderate intervals by hard knots. But they acquire still greater strength from their tubular form; for the matter they contain, being thus removed to a greater distance from the fulcrum, exerts its cohesion with proportionally more effect, in withstanding any lateral impulsion. The bones of animals are likewise rendered stronger by their fistular structure, and their partition into short members connected by large compact joints. Hence, in the construction of fine mechanical and astronomical instruments, hollow brass cylinders, on account of their stiffness and lightness, are now preferred to solid pillars. If a beam be supported horizontally at both ends, and loaded in the middle, the pressure will be equally shared between the props; the effect is the same as if it were fixed at the middle, and each end pulled upwards by half its load. The breaking weight is consequently double that required to tear a beam, of half the length, implanted in a wall. According to the principle of Galileo, therefore, this limit is inversely as the length of the beam, and directly as the breadth and the square of the depth. This result is confirmed by the numerous experiments which Buffon performed between the years 1738 and 1746. Thus, reducing all the quantities to English measures, an oaken beam, 4 inches square and 10 feet long, broke under the weight of 4016 lb.; and another beam of the same wood, 8 inches square and 20 feet long, was broken by a load of 16,700 lb. The latter, being twice as thick, should have been eight times stronger with the same length; but the length being doubled, again reduced the excess to four times.

4. In its Resistance to the Effort of Twisting or Torsion.—A cylindrical body suspended vertically, but having its upper end fixed, may be wrenched or turned round through any angle, by the exertion of some lateral force; and if its elasticity be not thus impaired, it will, after the deranging influence has ceased, return to its former position, and perform this retrocession in a certain time. Many substances may be considered as only bundles of parallel fibres, which by twisting exert an augmented longitudinal force. It will be more accurate, however, to view materials in general as composed of particles equally distributed through the mass.

STREPITOSUS, the name of a disease common to the inhabitants of some parts of the Alps, in which the face, neck, and arms are so distended with flatulencies as to sound, on being struck, like a dry bladder half distended with wind.

STRETCHER, a narrow piece of plank placed athwart the bottom of a boat, for the rower to place his feet against, in order to communicate a greater effort to his oar.

STRETCHING, is generally understood to imply the progression of a ship under a great surface of sail, when close hauled. The difference between this phrase and standing, is apparently in the quantity of sail, which, in the latter, may be very moderate, but in stretching generally implies considerable, as, 'We were standing in shore (under easy sail) when we discovered the enemy stretching to the southward,' that is, under a crowd of sail.

STRIKE, a measure of capacity, containing four pecks.

STRIKE, among Seamen, is a word variously used. When a ship, in a fight, or on meeting with a ship of war, lets down or lowers her top-sails at least half-mast high, they say she strikes, meaning she yields, or submits, or pays respect, to the ship of war. Also, when a ship touches ground, in shoal water, they say she strikes. And when a top-mast is to be taken down, the word of command is, Strike the top-mast, &c.

STRING, in Ship-building, the highest range of planks in a ship's ceiling, or that which lies between the gunwale and the upper edge of the upper-deck ports.

STRIX, the Owl, in Natural History, a genus of birds of the order of Accipitres. Birds of this genus are rapacious. They are seldom seen by day, secluding themselves in the hollows of trees and buildings, and unable, from the particular structure of the eye, to endure the glare of sunshine. When they do appear in the day, they are pursued and persecuted by a variety of small birds, who combine in their expressions of ridicule and aversion, and soon oblige them to recur again to their retreat. During the season of general repose, they are active in quest of food, which in darkness they perceive with facility, and disturb the silence of night by loud and reiterated screams. Their usual prey consists of bats, mice, and small birds. Latham enumerates forty, and Gmelin fifty species.

STROKE, a single sweep of the oars in rowing. Hence we say, 'Row a long stroke;' which is intended to move the vessel forward more steadily.

STROKESMAN, the person who rows the aftmost oar in a boat, and gives the stroke which the rest are to follow, so that all the oars may operate together.

STRONTIAN, about the year 1737, a mineral was brought to Edinburgh by a dealer in fossils, from the lead mine of Strontian, in Argyleshire, where it is found imbedded in the ore, mixed with several other substances. It is sometimes transparent and colourless, but generally has a tinge of yellow or green. Its specific gravity varies from 3.4 to 3.726. Its texture is generally fibrous; and sometimes it is found crystallized in slender prismatic columns of various lengths. Strontian is found abundantly in different places of the world, and always combined with carbonic acid, or sulphuric acid.

STRONTIUM, the metallic basis of strontia.

STROP, a piece of rope, spliced generally into a circular wreath, and used to surround the body of a block, so that the latter may be hung to any particular situation about the masts, yards, or rigging. Strops are also used occasionally to fasten upon any large rope for the purpose of hooking a tackle to the eye or double part of the strop, in order to extend or pull with redoubled effort upon the same rope; as in setting up the rigging, where one hook of the tackle is fixed in a strop applied to the particular shroud, and the other to its laniard.

STRUTHIO, the Ostrich, in Natural History, a genus of birds of the order Gallinæ. The black ostrich, is about eight feet long, and when erect measures about seven feet, and sometimes eight in height. One was exhibited in London in 1760, weighing three hundred pounds. It is found in various parts of Africa, and about the Cape of Good Hope is particularly abundant. In the parts of Asia, near Africa, it is also met with. The ostrich subsists entirely on vegetable productions, but will swallow, occasionally, the most hard and even sharp-pointed substances. Iron, and various other metals, and even glass, have often been found in its stomach, and have unquestionably often proved fatal. It is related, upon respectable authority, that an ostrich will carry a man upon his back, and move with very considerable speed: some make the same remark with respect to two men. When unencumbered by any burden, its speed is truly extraordinary, and will exceed, in some instances, the ordinary rapidity of a horse. Dogs are sometimes employed to hunt them down, followed by men on horseback, who contrive, by means of a long hooked staff, to lay hold of one of the legs of the bird, and thus bring it to the ground. They are applied to various purposes. Their feathers form an admirable ornament for the ladies; their skins are of sufficient thickness to be manufactured for the purpose of leather.—The galeated cassowary, is nearly equal in magnitude to the ostrich, but has a much shorter neck, and therefore is greatly inferior in height. On the top of its head is a species of helmet three inches high,

and one thick at the base. Each wing, or what appears as such, is destitute of feathers, and has five bare shafts like those of the porcupine, and the body is covered with loose webbed feathers of a rusty black colour. It is never found beyond the tropical limits, and is no where abundant within them. It is unable to fly, but runs with great speed; and though it lives only on vegetables and fruits, which it is said to swallow unbroken, it is courageous, and even sometimes ferocious, and employs its legs to annoy its adversary by kicking.—The New Holland cassowary, is very similar to the above, but considerably longer.

STRYCHNIA, a newly-discovered vegetable alkali. MM. Pelletier and Caventon, whilst analyzing the vomica nut, and the bean of St. Eustatia, have extracted from these two seeds a substance to which they owe their action on the animal economy.

STUB, in Agriculture, a term signifying the root of a plant with the top cut off. To *Stub*, is to grub up the roots or stumps of trees, shrubs, or brushwood, left in the ground after the tops are cut off.

STUBBLE, the strawy matter of the cut stalks, or stems of grain, remaining in the ground after reaping. In some parts of Essex, when mixed with much grass and weeds, it is burnt in the field. This tends to destroy the weeds, and the ashes become manure.

STUCCO, in Building, is a composition of white marble pulverized, and mixed with plaster or lime, the whole sifted and wrought up with water, to be used like common plaster. Of this composition are made statues, busts, bas-reliefs, and other architectural ornaments. A stucco for walls, &c. may be formed of the grout or putty made of good stone-lime, or the lime of cockle-shells, which is better, properly tempered and sufficiently beat, mixed with sharp grit-sand, in a proportion which depends on the strength of the lime: drift-sand is best for this purpose, and it will derive advantage from being dried on an iron plate or kiln, so as not to burn; for thus the mortar would be discoloured. When this is properly compounded, it should be put up in small parcels against walls, or otherwise, to mellow, as the workmen term it; reduced again to a soft putty, or paste, and spread thin on the walls without any under-coat, and well trowelled. A succeeding coat should be laid on, before the first is quite dry, which will prevent joints of brick-work appearing through it. Much depends upon the workmen giving it sufficient labour, and trowelling it down. If this stucco, when dry, is laid over with boiling linseed oil, it will last a long time, and not be liable, when once hardened, to the accidents to which common stucco is liable.

Liardet's, or, as it is commonly called, Adam's oil-scent, or stucco, is prepared in the following manner: For the first coat, take twenty-one pounds of fine whiting, or oyster-shells, or any other sea-shells calcined, or plaster of Paris, or any calcareous material calcined and pounded, or any absorbent material whatever, proper for the purpose; add white or red lead at pleasure, deducting from the other absorbent materials in proportion to the white or red lead added; to which put four quarts, beer-measure, of oil; and mix them together with a grinding-mill, or any levigating machine: and afterwards mix and beat up the same well with twenty-eight quarts, beer-measure, of any sand or gravel, or of both, mixed and sifted, or of marble or stone pounded, or of brick-dust, or of any kind of metallic or mineral powders, or of any solid material whatever, fit for the purpose. For the second coat, take sixteen pounds and a half of superfine whiting, or oyster-shells, or any sea-shells calcined, &c. as for the first coat; add sixteen pounds and a half of white or red lead, to which put six quarts and a half of oil, wine-measure, and mix them together as before: afterwards mix and beat up the same well with thirty quarts, wine-measure, of fine sand or gravel sifted, or stone or marble pounded, or pyrites, or any kind of metallic or mineral powder, &c. This composition requires a greater proportion of sand, gravel, or other solids, according to the nature of the work, or the uses to which it is to be applied. If it be required to have the composition coloured, add to the above ingredients such a proportion of painter's colours as will be necessary to give the tint or colour required. In making the composition, the best linseed or hempseed, or other oils proper for the purpose, are

to be used, boiled or raw, with drying ingredients, as the nature of the work, the season, or the climate, requires; and in some cases, bees-wax may be substituted in place of oil: all the absorbent and solid materials must be kiln-dried. If the composition is to be of any other colour than white, the lead may be omitted, by taking the full proportion of the other absorbents; and also white or red lead may be substituted alone, instead of any other absorbent material. The first coat of this composition is to be laid on with a trowel, and floated to an even surface with a rule or darby, (i. e. a handle-float.) The second coat, after it is laid on with a trowel, when the other is nearly dry, should be worked down and smoothed with floats edged with horn, or any hard smooth substance that does not stain. It may be proper, previously to laying on the composition, to moisten the surface on which it is to be laid, by a brush with the same sort of oil and ingredients which pass through the levigating machine, reduced to a more liquid state, in order to make the composition adhere the better. This composition admits of being modelled or cast in moulds, in the same manner as plasterers or statuarys model or cast their stucco work. It also admits of being painted upon, and adorned with landscape, or ornamental, or figure-painting, as well as plain painting. For the invention of this stucco, Mr. Liardet obtained a patent in 1773 for fourteen years, the term of which was extended to eighteen years, in consequence of an act of parliament in 1776. For compositions very similar to the preceding, patents were granted to Dr. Wark in 1765, Mr. Emerton in 1771, and to Mr. Rawlinson in 1772.

Dr. Shaw informs us in his *Travels*, (p. 286.) that the cement or mortar used in Barbary, which is apparently of the same consistence and composition with that of the ancients, is made in the following manner: They take two parts of wood-ashes, three of lime, and one of fine sand, which, after being well sifted and mixed together, they beat for three days and nights incessantly with wooden mallets, sprinkling them alternately and at proper times with a little oil and water, till they become of a due consistence. This composition, he adds, is chiefly used in their arches, cisterns, and terraces; but the pipes of their aqueducts are joined, by beating tow and lime together with oil only, without any mixture of water. Both these compositions quickly assume the hardness of stone, and suffer no water to pervade them; and will, therefore, answer the purpose of stucco.

STUDDING-SAILS, certain sails, extended in moderate and steady breezes beyond the skirts of the principal sails, where they appear as wings to the yard-arms. The top-mast and top-gallant studding-sails are those which are set on the outside of the top-sails and top-gallant-sails. They are spread at the foot by booms, which slide out on the extremities of the lower and top-sail yards, and their heads or upper edges are attached to small yards, which are hoisted up to the top-sail and top-gallant yard-arms. The lower studding-sails, which are spread beyond the leeches of the main-sail, are fixed nearly in the same manner, only that the boom which extends the foot is hooked to the chain by means of a goose-neck, or else swings off with the sail to which it is suspended, being kept steady abaft by a rope called the guy.

STUFF, in Commerce, is a general name for all kinds of fabrics of gold, silver, silk, wool, hair, cotton, or thread, manufactured on the loom; of which number are velvets, brocades, mohair, taffeties, cloth, serges, &c. The term is also used more particularly to denote slight woollen articles used principally for linings and women's apparel.

STUFF, any composition or melted mass, used to smear or daub the sides or bottom of a ship. The stuff which is chiefly used for the lower masts, is simply turpentine, resin, or varnish of pine; for the top-mast, tallow or butter; for the sides, turpentine, varnish of pine, tar and oil, or tar mixed with oil and red ochre; and for the bottom, a mixture of tallow, sulphur, and resin or tar, whale oil and broken glass, or any part of these ingredients; and this application is called giving a new coat of stuff to the masts, sides, &c.

STUM, in the Wine Trade, is a name for the unfermented juice of the grape, when it has been several times racked off, and separated from the sediment. The casks are for this purpose well fumigated with brimstone, in order to prevent

fermentation, through which the juice would become wine. See **MATCHING**.

STUMP, a name given to the root part of any solid body, particularly of trees, remaining after the rest are taken away.

STUPA, a numbness occasioned by any bandage that stops the motion of the blood and nervous fluids, or by a decay in the nerves, as in paralytic strokes, &c.

STURDY, a disease very prevalent among sheep, and which terminates fatally if not relieved in its early stages.

STURGEON, a well-known, large, and fine-tasted fish, which spends part of its time in rivers and part in the sea.

STURGEON. See **ACCIPENSER**.

STYCHNOS, in Botany, a genus of the pentandria monogynia class and order. Natural order of *Luridæ apocinæ*, Jus-sieu. There are three species; we shall notice the *S. nux vomica*, poison nut. It is a native of the East Indies, and is common in almost every part of the coast of Coromandel, flowering during the cold season. The wood is hard and durable, and is used for many purposes by the natives. The root is used to cure intermitting fevers, and bites of venomous snakes. The seed of the fruit is the official *nux vomica*.

STYLE, a word of various significations, originally deduced from a kind of bodkin, wherewith the ancients wrote on plates of lead, or on wax, &c. and which is still used to write on ivory leaves, and paper prepared for that purpose, &c.

STYLE, in Chronology, denotes a particular manner of accounting time. Style is either old or new. The old style is that mode of computing time which is called the Julian, and is still followed in some states, that refuse to admit the reformation of the calendar. The new style is that of Gregory XIII. which is followed by the Catholics, and by most Protestant kingdoms.

STYLE, in Dialing, denotes the gnomon of a dial, raised on the plane of it, to project a shadow.

STYLE, in Grammar, is a particular manner in which individuals express their thoughts either in writing or speech, agreeably to the rules of syntax. *Style* has various other acceptations, as applied to music, oratory, poetry, philosophy, mathematics, &c.

STYLET. See **STILETTO**.

STYPTIC, a remedy that has the virtue of stopping blood, or of binding up the aperture of a wounded vessel. Many waters and powders are of this description; but in most, vitriol is the chief ingredient.

STYRAX, the *Storax Tree*, a genus of plants belonging to the class of decandria, and to the order of monogynia, and in the natural system ranging under the 18th order, bicornes.

SUBALTERN, an inferior officer, who discharges his post under the command of another, to whom his duty is to yield obedience.

SUBERATS, salt formed with the suberic acid.

SUBERIC ACID, an acid obtained from cork.

SUBJECT, in Legislation, a person under the dominion of a sovereign prince or state. Under the feudal system, those who held lands or tenure under the barons were deemed their subjects. In Anatomy, a body obtained for dissection is called a subject. In Logic, subject is that about which the thoughts and understanding are employed.

SUBLIMATE. See **CORROSIVE SUBLIMATE**.

SUBLIMATION, in Chemistry, an operation by which volatile substances are collected and obtained. It is nearly allied to distillation, excepting that in the latter the fluid parts only of bodies are raised, whereas in sublimation the solid and dry are collected.

SUBLIMITY, a term applicable to external objects, whether works of nature or of art, as well as to powerful language, and, in short, to whatever is calculated to raise grand, terrible, and magnificent ideas. It elevates the mind above ordinary scenes, and fills it with wonder and astonishment.

SUBMULTIPLE, in Geometry, is a number or quantity contained in another, which being repeated a given number of times, becomes exactly equal to it. Thus 3 is a submultiple of 21.

SUBNORMAL, in Geometry, is a line which determines the point, in the axis of a curve, where the normal or perpendicular, raised from the point of contact of a tangent to the curve, cuts the axis.

SUBORNATION, a secret or underhand preparing or instructing a witness to give a false testimony. It is defined as an act that allures or disposes to perjury.

SUBPOENA, is a writ whereby all persons under the degree of peers are called into Chancery, in such case only where the common law fails, and has made no provision; so as the party who in equity hath wrong, can have no other remedy by the rule and course of common law. It is therefore the commencement of a suit in equity. But the peers of the realm in such cases are called by the lord chancellor's or lord keeper's letters, giving notice of the suit intended against them, and requiring them to appear. There is also a *subpoena ad testificandum*, or a subpoena to give evidence for the summoning of witnesses, as well in Chancery as other courts. There is also a subpoena in the Exchequer, as well in the court of equity there, as in the office of pleas; which latter is a writ that does not require personal service, and is the commencement of a suit at common law.

SUBSCRIPTION, in Civil concerns, is the signature put at the bottom of a letter, writing, or instrument.

SUBSCRIPTION, in Commerce, is used for a share which particular persons hold in a public stock, or a trading company.

SUBSCRIPTION, in the Book Trade, is an engagement to take a given number of copies, on some stated terms. Subscription to the thirty-nine articles of religion, is a solemn declaration of the subscriber's assent to the doctrines and precepts they contain.

SUBSIDY, in Law, signifies an aid or tax granted to the king by parliament, for the necessary occasions of the kingdom.

SUBSTANCE, something that is capable of subsisting without dependence upon any created being, or any particular modes or accidents. There are but two kinds of substance known to exist, namely, matter and spirit. The former is distinguished by its magnitude, extension, &c. and the latter by its consciousness, understanding, and volition.

SUBSTANTIVE, in Grammar, a noun, or name, considered simply and in itself.

SUBSTITUTE, a person appointed to officiate for another in case of absence, legal impediment, or agreement.

SUBTANGENT of a CURVE, in the higher Geometry, is the line which determines the intersection of the tangent with the axis; or, that determines the point wherein the tangent cuts the axis prolonged.

SUBTENSE, in Geometry, the same with the chord of an arch.

SUBTILE, in Physics, a thing remarkably small, fine, and delicate, such as the animal spirits, or the effluvia of odorous bodies, are supposed to be. The Cartesians suppose a very subtle matter to be the first element of their system.

SUBTRACTION. See ARITHMETIC.

SUBULARIA, rough-leaved alysson, or awlwort, a genus of plants belonging to the class of tetradynamia, and order of siliculosa; and in the natural method ranking under the 39th order siliquosæ.

SUBURBS, buildings which stand near to the walls or specific boundaries of a city or town, but are not included within their compass.

SUCCINATS, salts formed with the succinic acid; which see.

SUCCINIC ACID. Amber is a well-known, brown, transparent, and inflammable body, pretty hard, and susceptible of polish, found at some depth in the earth, and on the sea coast of several countries.

SUCTION, in Physiology, the act of drawing into the mouth fluids, and other substances, by removing from the part where the operation is performed, the pressure of the external atmosphere, whilst on every other portion all its power remains unobstructed. Suction is little more than the formation of a partial vacuum, into which, when made by the mouth or otherwise, the fluid immediately flows.

SUFFERANCE. Tenant at sufferance, is he who holds over his term at first lawfully granted. A person is tenant at sufferance who continues after the estate is ended, and wrongfully holds against another, &c.

SUFFOCATION, the termination of life by impeded respiration. This may be occasioned three ways, by hanging, drowning, or by carbonic acid gas.

SUFFRAGAN, a titular bishop, appointed to aid and assist the bishop of the diocese.

SUGAR, SACCHARUM, a very sweet, agreeable, saline juice, expressed from a kind of canes, or reeds, growing in great plenty in the East and West Indies. Pure sugar is perfectly transparent and colourless, when crystallized; but when granular, of a pure gloss of white, soluble in water and alcohol, without smell, and with a simply sweet taste, having no other flavour.

It is a question not yet decided among botanists, &c. whether the ancients were acquainted with this cane, and whether they knew how to express the juice from the same? What we can gather from the arguments advanced on either side is, that if they knew the cane and juice, they did not know the art of condensing, hardening, and whitening it; and of consequence, they knew nothing of our sugar.

Dr. William Douglas, in his Summary, &c. of the first planting of our American settlements, printed at Boston in 1751, and reprinted at London in 1755, affirms, that sugar was not known among the ancient Greeks and Romans, who used only honey for sweetening. Paulus Aegineta, he says, a noted compiler of medical history, and one of the last Greek writers on the subject, about anno 1625, is the first who expressly mentions sugar: it was at first called *mel arundinaceum*, i. e. *reed or cane honey*. He adds, that it came originally from China; by way of the East Indies and Arabia, into Europe, and was formerly used only in syrups, conserves, and such Arabian medicinal compositions.

Another question among the naturalists is, Whether the sugar-cane be originally of the West Indies, or whether it has been translated rather from the East? The learned of these last ages have been much divided on the point; but F. Labat, a Dominican missionary, in a dissertation published in 1722, asserts that the sugar-cane is as natural to America as India; and that the Spaniards and Portuguese first learned from the Orientals the art of expressing its juice, boiling it, and reducing it into sugar.

SUGAR CANE, in Botany. See SACCHARUM.

The root of this plant is jointed like those of the other sorts of canes and reeds, from which arise four, five, or more shoots, according to the age or strength of the root: these grow from eight or ten to twenty feet high, according to the richness of the ground; but those of middling growth are the best. The canes are also jointed, and the length, as well as the size of the joints, depend upon the weather and the soil; at each joint are placed leaves, the lower part of which embraces the stalk or cane to the next joint above their insertion, before they expand. The first joint, which comes out either at the third, fourth, or fifth month, according to the season and soil, always keeps in its first place near the earth; out of this comes the second, and out of the second a third, &c. each week producing its joint, or very nearly, and a corresponding leaf likewise drying and falling off nearly every week. A cane of thirty-two joints, which is fit to be cut, has from five to twenty-eight of them which have lost their leaves; the next five or six still have them, in a withered state, and ready to fall off; and the remaining joints, surrounded with green leaves, from the head, which is cut off after the leaf is withered. In a cane, whose length is from seven to nine feet, and which grows in a new, or a very moist and favourable soil, the number of useful joints is between forty and fifty, the first above the ground generally appearing at the end of three months, or, with frequent showers, a fortnight sooner; and many canes in such a soil are found rotten, or almost dried up, at the end of thirteen months: in a good soil, favourably exposed, well drained, and worked for a number of years, canes not shorter than four feet and a half have thirty-eight or forty joints, the first joint appearing about the fourth, or middle of the third month, and many canes that have been cut in such a soil at the end of fourteen or fifteen months, being found rotten or dried: in a dry, but good soil, not manured, but well worked, and seconded by the season, the canes have been from three to four feet long, and have had from thirty to thirty-four joints; the first joint coming out at the end of four, or four months and a half; and canes of this kind have been found standing at the end of fifteen months, but very dry, and sometimes a little changed: in a soil which is still drier, and more parched, canes which have been about two feet high, have had

from twenty-four to twenty-eight joints, the first of which appears at the end of the fifth month, and many of these canes have been dried at the end of fifteen months.

The time for cutting them is usually after twelve or fifteen months' growth, but this varies according to the soil and the season. Those which are cut toward the end of the dry season, before the rains begin to fall, produce better sugar than those cut in the rainy seasons, when they are more replete with watery juice, and require a greater expense of fuel to boil it. In those plantations where the number of negroes is small, sugar is made in almost all seasons indifferently, and consequently the canes are planted when the planter is best prepared for his work, rather than at the most advantageous time. The system of cultivation among planters who are better supplied in respect of labourers, consists in planting a fourth or fifth of their land in October, November, and December; in digging very deep trenches, for the greater nourishment of the root; in planting at great distances, for the benefit of a freer circulation of the air; and in cutting the canes in the four finest months, viz. February, March, April, and May, because the sugar is then the finest, the canes are cut with the least trouble, and supply (as is supposed) greater quantities of it. Those who adopt this method, cut about three-fourths of their plantations, the remaining being made up of young canes, to be cut the following year, and for new plants.

The manure generally used in sugar planting, is a compost formed of the coal and vegetable ashes drawn from the fires of the boiling and still houses; feculences discharged from the still house, mixed with rubbish of buildings, white lime, &c.; refuse, or field trash, i. e. the decayed leaves and stems of the canes, so called in contradistinction to cane trash used for fuel; dung, obtained from the horse and mule stables, and from cattle pens; and good mould, collected from gullies, or other waste places, and thrown into the cattle pens.—When the ratoon or canes are ripe, as they ordinarily are in twelve or fifteen months, or, as Mr. Cazaud apprehends, in eleven or twelve months, they are cut, and carried in bundles to the mill.

SUGAR, Making of.—When the plants have attained their full growth, which, in the West Indies, is from twelve to fourteen months, the canes are cut short, tied up into bundles, and brought to the Crushing Mill, of which the following is a representation of those in common use.

Description.—A large block, *a*, is enclosed by a strong frame of timber; the upper surface of this block is hollowed out into the form of a basin, to receive the juice of the canes, which is expressed by the three vertical cylindrical rollers *c*, *b*, *d*, whose lower pivots work in sockets which are fixed in the block *a*, and the upper in *e*. The upper and lower sockets, in which the pivots of the middle roller revolve, are fixed immovably; but the sockets of the other two are held between wedges, (as shewn in the engraving,) which are put in contrary directions, the small end of one wedge being on the same side as the large end of the other; by which means the rollers may be either set farther from or nearer to each other. When it is required to set the outside rollers nearer to the middle roller, that wedge which is nearest the middle roller is to be driven out, and the other driven in; and the contrary when they are wanted farther asunder. These rollers are usually made of cast iron, having each a cog-wheel at the upper end on the same shaft, which causes

them all to turn together, when the power of a first mover is applied to the middle roller, by the shaft *f*.

Behind the middle roller is a circular or concave piece of iron or wood, (not shewn in the above engraving) which is called the dumb returner, a name obviously given to the circumstance of a man being always employed, previous to the invention of this part of the apparatus, to perform the same office. In working the mill, a man takes a bundle of the canes, and applying them between the first and second rollers, (*c* and *b*) they are drawn in and pressed between them, but instead of proceeding in a right line, the ends of the cane strike against the concave surface of the dumb returner, which bends them round the middle roller, and causes them to enter between the second and third rollers (*b* and *d*) which are placed somewhat nearer to one another than *c* and *b*, as the canes have already received great compression, and when they are thus returned through the front, they are received and carried off by another man. The expressed juice runs down the rollers into the reservoir, and is conveyed by the trough *g* to the boiling-house. It should be observed, that the reservoir on the top of the block *a* is only cut into channels round the outside of the rollers, to prevent the liquor running down and getting out between the wedges before mentioned. If a sugar mill be worked by the wind, the shaft *f* is connected with the vertical shaft of the mill. If by horses, the levers they work from are fixed to the shaft *f*, and the horse walk is either raised above ground higher than the trough, or the juice is conveyed by a pipe laid under the walk. Sugar-mills that are worked by a water wheel or steam-engine, have a bevelled wheel fixed upon the shaft *f*, and another upon the wheel or engine which turns it. Such is the pressure given to the canes in passing between the rollers of the mill, that they are not only squeezed completely dry, but are often reduced to powder. The refuse or macerated rind of the cane, which is called cane trash, serves for fuel to boil the liquor in the subsequent operations.

The sugar is obtained by the following process:—The juice from the mill runs from the receiver to the boiling house, along a wooden gutter lined with lead. In the boiling house it is received into one of the copper pans or caldrons, called clarifiers. Of these there are generally three; and their dimensions are determined by the power of supplying them with liquor: there are water mills that will grind with great facility, sufficient for thirty hogsheads of sugar in a week. Methods of quick boiling cannot be dispensed with on plantations thus fortunately provided; for otherwise the cane liquor would unfortunately become tainted before it could be exposed to the fire. The purest cane juice will not remain twenty minutes in the receiver without fermenting; hence clarifiers are sometimes seen of a thousand gallons each; but on plantations that during crop time make from fifteen to twenty hogsheads a week, three clarifiers of three or four hundred gallons each are sufficient. The liquor, when clarified, may be drawn off at once with pans of this size, and there is leisure to cleanse the vessels every time they are used. Each clarifier is furnished with a syphon or cock, to draw off the liquor clear and free from the scum which is thrown up during the boiling.

In order to assist in the separation of the gum, oil, and other vegetable principles which are intermixed in the expressed juice, and for the purpose of neutralizing the superabundant acid, a quantity of Bristol white lime, in powder, or in solution, is stirred into it, and in the proportions and manner of effecting this, according to the state of the liquor, consists one of the principal difficulties in sugar making. In this first process of clarification the liquor is not suffered to boil, but is allowed to do so when drawn off clear into the next pan, which is called the *repeating copper*; here the ebullition is continued (and the froth or scum removed by skimmers as it rises) until it becomes of such a consistence, as to be reduced in quantity very considerably, so that it may be contained in a much smaller copper, into which it is next ladled. The liquor is now bright, and of the colour of Madeira wine. In this state, and of a certain consistence, it undergoes a farther evaporation in the vessel called the *teach*, until it is so far condensed as to be capable of granulating when cool. The next operation is that of striking, which consists in ladling the thick liquor into the cooler.

The cooler (of which there are usually six, is a shallow wooden

vessel about eleven inches deep, seven feet in length, and from five to six feet wide, and is capable of holding a hoghead of sugar. Here the sugar grains, as it is called; i. e. it runs into a coarse irregular mass of imperfect crystals, separating itself from the molasses. From the cooler it is taken to the curing-house.

The curing house is a large airy building, provided with a capacious molasses cistern, the sides of which are sloped, and lined with terras or boards. A frame of massive joist work without boarding is placed over this cistern; and empty hogheads without headings are ranged on the joists of this frame. Eight or ten holes are bored in the bottoms of these hogheads, and through each of the holes, the stalk of a plantain leaf is thrust, six or eight inches below the joists, and long enough to stand upright above the top of the hogheads. Into these hogheads the mass from the coolers is put, which is called *potting*; and the molasses drains through the spongy stalks of the plantain leaves, and drops into the cistern beneath; from whence it is occasionally taken for the making of rum by distillation. In the space of three weeks the sugar becomes tolerably dry and fair; it is then said to be cured, and the process finished. Sugar thus obtained, is called the *muscovado*, and is the raw material whence the British sugar-bakers make their loaf or refined lump sugar.

Several methods of clarifying have been adopted, and are still in use; that, however, invented by Mr. Smith, and for which he obtained a patent, is entitled to a decided preference. The burning of the cane trash had been found injurious to the molasses, but his steam apparatus, represented in the engraving, completely remedies this defect.

Reference to the Engraving.—*a*, is the finishing pan, or teach, *b*, the evaporating copper, *c*, the clarifier; this last is gently heated by the flue *f* from the distant fires, *a* and *b* are heated by the same fire, through the medium of two separate steam boilers, *d d* and *e e* shews the depth of water they contain; *g* is the fire-door, *h* the ashpit, *i* the feed-pipe for supplying water when necessary, one of which is employed to each steam boiler. *k k* are safety valves for regulating the pressure of the steam, *m* the chimney. Cocks are fixed to each of the boilers for drawing off the water and the steam, which cannot be shewn in the sec-

tional view. We shall now conclude by quoting some of the observations of the patentee on the subject. The bottom of the boilers is flat, and the spaces between them and the bottom of the sugar-pan forms the boiler, which need not exceed a foot in depth for the largest apparatus. If the pans project beyond the boilers, it will be found advantageous; for the sides being cooler than the other parts, the fluid is prevented from boiling over, and the scum, as it forms, is thrown on the sides, and collected with greater facility. The steam being applied to every part of the bottom of the pan, communicates its heat to the liquor therein, and being thereby condensed, descends in drops of water to the bottom of the boiler, and is again raised into steam by the heat of the fire underneath, so that the operation continually goes on, of generating and condensing in the same vessel, thus dispensing with force pumps and complicated feed pipes; however unequally the fire may act on the boiler, the effect on the bottom of the sugar pan is perfectly equalized by the intervening stratum of steam, an advantage peculiar to this apparatus. The steam boiler and sugar pan are made of thin copper, or iron; and to give sufficient strength to large sur-

faces, they are united by riveted bolts at short and equal distances, thus enabling this metal to resist any required pressure of steam.

SUGAR, Refining of, is the art of purifying sugar, and of giving a superior degree of whiteness and solidity. The excellence of muscovado sugars, or such as have not been refined by the planter, but are sent home in the most crude state, consists in their whiteness, dryness or freeness, cleanness and sharpness, or strength. The judicious refiner decides upon these several qualities by the eye, the touch, and the taste. The first operation in the process of refining is that of *clearing the pan*; previously to which they are charged, by throwing about six quarts of fresh bullock's blood (called *spice*) into each pan, and filling it with lime-water to about half the height from the bottom to the part in which the brace is fixed; and when these are well stirred together, the pan is filled to the brim with raw sugar. This mass, with a moderate fire, will, in about two hours, be brought to the verge of boiling heat; but it should not be allowed actually to boil; and in this time the earthy particles of the sugar, and other adventitious impurities, will be separated from it by the effect of the heat, and the cleansing quality of the spice, and thrown up to the surface. About two quarts of spice are added to each pan, within the first hour after the fires are lighted. The scum thus produced, which is usually from four to ten inches thick, is fit to be taken off, when the surface appears black and dry, and not greasy; and it is gently removed with a broad skimmer into a portable tub, and conveyed into the scum-cistern. Having done this, the panman stirs together a ladleful of spice, (*s. gr.* about a quart,) and a quantity of lime water (*s. gr.* one or two gallons, as the case may require); and pours this mixture into each pan. When the sugar is again brought to a scalding heat, it throws up a second scum, not so foul as the first, which is removed as before. He then adds a fresh quantity of spice, but less than the former, and repeats this operation till the sugar casts up a clean milky froth, which indicates that the impurity is wholly extricated. The liquor is also sometimes examined with a bright silver or metal spoon, that any remaining foulness may be discovered. In the making of double leaves, powder leaves, or very fine single leaves, it is usual to brighten the natural colour of the sugar by the addition of a little blue. For this purpose, when the pans are almost clear, the quantity of about six pennyweights troy of the finest indigo, finely powdered, and filtered through a piece of woolen or blanketing in a basin of fresh water, and well stirred together in a bason, is thrown into each pan. The sugar being once raised in the pan after this infusion, the grosser particles of the colour are taken off in the last scum, and the remainder is incorporated with the sugar in the pan.

The panman having brought the sugar to the cleanest state, prepares to skip it off, or to shift it from one vessel to another; this is done by means of a wooden gutter laid along the pans, and opening into the clarifying cistern. Over this cistern upon large iron bars is fixed an oblong basket, about sixteen inches deep, in which a large thick blanket is fastened: and through this blanket and basket the sugar liquid passes out of the gutter; and to the mass a quantity of syrup is usually added. Having measured the quantity of liquid in the cistern with a rod graduated by inches, the panman pumps back into the pans either the sixth or ninth part of the whole, as he is directed by the supervisor or boiler; and the pans are all supplied together by means of a trough. When this is done, the fire is stirred up to a considerable degree of fierceness; and then commences a new operation, viz. evaporation. In this part of the process (the day's work being divided into three fillings), the panman pumps into the pan one-ninth part of the quantity in the cistern, which in a few seconds begins to boil, and must be continued in a boiling state, but not with too intense a fire; and to prevent the sugar from boiling up to the surface of the pan, or from boiling over, he casts a small quantity (*viz.* a piece as large as a nutmeg or walnut, as the case may require) of butter or grease into the boiling liquor. Here it is to be observed that sugar should boil low in the pan, and yet not too flat like water, for by rising hollow from the bottom, the necessary evaporation is retarded, and the sugar is exposed to the action of the fire for a longer time than it ought to be. In a space of time from

twelve to thirty minutes, the evaporation will have produced its effect, and the sugar acquired the requisite degree of viscosity. This state will be indicated by various circumstances; as the bubbles dragging heavily over the surface of the boiling mass, and by the clammy liquid falling in ropes from the proof-stick: but principally by that test which is called the proof. For this purpose the boiler draws the stick out of the boiling liquid with his right hand, and placing his left thumb upon the sugar, draws it across the stick, carrying away upon the end of his thumb as much of the sugar as will hang upon it; he then, by means of a candle placed in a black box called the proof-box, and by repeated trials (drawing the sugar to a thread between his thumb and fore-finger) determines when the evaporation is complete; and when this is decided, the fire is smothered, and nearly quenched. The hot sugar liquor is then removed by means of basons out of the pans into coolers, two or three gallons being left in each pan, to prevent the bottom from being scorched; and the pans are again supplied with a quantity of liquor for the next evaporation. The liquor in the coolers is gently stirred, to prevent a crust from forming on its surface.

The next operation in refining is conducted in that part of the ground-floor of a sugar house, which is denominated the *fill-house*, because all the upper floors of the house are to be filled from this; and this operation consists in filling the moulds with the three skippings contained in the coolers. The moulds, in the form of inverted cones, previously prepared by soaking and washing them, and stopping their apertures with wet linen rags, are placed side by side, and in rows two or three deep; their number is to suffice for the quantity of liquor in the coolers, which is estimated by the number of basons which were skipped off from the pans; and they are propped up by other moulds (commonly such as are broken) placed with the broad end downwards, in front of the outward rank, by way of abutment; these are called *stayers*. The sugar being previously stirred in the coolers in order thoroughly to mix, each skipping is ladled out of the coolers in succession, and not all at once, (unless the fillings are small, in loaves, and always in lumps,) into basons conveniently situated; and these are carried into the fill house, where as much of the sugar is poured into each mould as will fill about one third of its capacity; the same quantity is again poured into each; and at the third time they are filled to the brim.

The moulds being filled, the next operation, which is that of stirring the sugar in them, is called *hauling*, and is designed to prevent an adhesion to the mould, and to lay the grain of the mass even and regular through all its parts. In this business each man takes a tool made of wainscot, called a knife, and in size proportioned to that of the mould to be stirred; with this tool, keeping his hand over the centre of the mould, he scrapes the sugar from its sides by successive strokes downwards, carried all round; and when two revolutions are performed, the sugar is allowed to rest some minutes, until it has acquired some firmness. The moulds being stirred round three or four times, according to the direction of the boiler, are no more disturbed till they are pulled up.—The process already described relates to sugar *once refined*, called single loaves: double loaves are usually cleared with the whites of eggs instead of spice, (two hundred of which are necessary to each pan,) and with fresh water instead of lime water. With respect to the proof, one rule only can be laid down, viz. the sugar must be boiled higher as the moulds which contain it are enlarged.

SUGAR of Roses, is white sugar clarified, and boiled into the consistence of rose water. When thus prepared, it is formed into small lozenges, and sometimes into grains about the size of peas, by keeping it stirred until cold and dry. It is thought serviceable to soften and allay acrimonies, &c. of the breast.

SUGAR Spirit. This is a name given by distillers to a spirit made in England, Holland, and many other places, from the scum, washings, dross, and waste of a sugar-refining house. It is prepared in the same manner with that from malt and molasses, and is frequently used to adulterate brandy, rum, &c.

SUGAR of LEAD. Acetate of lead.

SUICIDE, voluntary self-murder; the definitions of which, under all the circumstances that may occur, their various connexions and consequences, involve many curious, paradoxical, and perplexing questions.

SUIT, in Law, is used in different senses, as, 1. Suit personal. 2. Suit of court, or suit service, is an attendance that tenants owe to the court of their lord. 3. Suit covenant, is where the ancestor hath covenanted with another to sue to his court. 4. Suit custom, when a man and his ancestors have been seized, time out of mind, of his suit. 5. Suit real, or regal, when men come to the sheriff's torn or leet. 6. Suit signifies the following one in chase, as fresh suit. 7. It signifies a petition made to the king or any great person.

SUKOTYRO, a genus of quadrupeds, of the order bruta; generic character, horn on each side near the eyes.

SULPHATES. Definite compounds of sulphuric acid with the salifiable bases.

SULPHITES. Definite compounds of sulphurous acids with their bases.

SULPHUR, is a well-known substance, sold in the form of a powder, or in solid pieces, when it is called brimstone. It is found in the neighbourhood of volcanoes: in the tract of land between Naples and the ancient Baie, called Solfaterra, the smoking plains, the remnant of a half-extinguished volcano, it is found in great abundance. Sulphur is brought in large quantities to this country from Mount Etna in Sicily, but is to be found in greater or less quantities near all volcanoes, of which the number throughout the world is very great. Sulphur is often found in coal mines, and indeed the common coal in our fires more or less contains this mineral. It is often found combined with iron, copper, and other metals, when it is called pyrites.

SULPHURETS, are combinations of alkalis, earths, or metals, with sulphur; hence a substance is said to be "sulphuretted," when it is combined with sulphur.

SULPHURIC ACID, is generally procured by burning a mixture of sulphur and nitre in chambers lined with lead. Sulphuric acid is a liquid somewhat of an oily consistence, transparent and colourless as water, without any smell, and of a very strong acid taste. When applied to animal or vegetable substances, it very soon destroys their texture.—Sulphuric acid may be procured by the following process: put into a glass retort two parts of sulphuric acid and one part of mercury, and apply the heat of a lamp; the mixture effervesces, and a gas issues from the beak of the retort, and may be received in glass jars filled with mercury, and standing in a mercurial trough. This gas is sulphuric acid.

SUM, in Mathematics, signifies the quantity that arises from the addition of two or more magnitudes, numbers, or quantities together.

SUMACH. Common sumach (*rhus coriaria*) is a shrub that grows naturally in Syria, Palestine, Spain, and Portugal. In the two last it is cultivated with great care. Its shoots are cut down every year quite to the root, and after being dried, they are reduced to a powder by a mill, and thus prepared for the purpose of dyeing and tanning.

SUMMONS, in Law, the citing or calling a person into any court, to answer a complaint, or to give evidence in cases that may require his testimony.

SUN. See **ASTRONOMY**.

SUNDAY, the first day of the week, and thus called by our idolatrous ancestors, because on this day the sun was worshipped. It is now more properly called the Lord's day, as commemorating the resurrection of our Lord; or Sabbath Day, being substituted under the gospel dispensation for the seventh day that was held sacred under the law.

SUPERCARGO, a person employed by merchants to go a voyage, and oversee their cargo or lading, and dispose of it to the best advantage.

SUPERFICIES, in Geometry, magnitude considered as having two dimensions, or an extension in length and breadth, but as being destitute of thickness or depth.

SUPERFINE, in the Manufactories, a word used to express the superlative fineness of a stuff. The term applies both to the materials and texture. Among gold and silver wire drawers, that is said to be superfine which is reduced to a hair-like size.

SUPERLATIVE, in Grammar, an inflexion of an adjective, denoting the highest or lowest degree of the quality the word was intended to express. In English, the superlative is gene-

rally formed by the addition of *est*, as *wisest*, *poorest*, *blackest*, &c. When the word has more than two syllables in its positive state, the superlative is expressed by the prefixing of *most*, as *most honourable*, *most tremendous*.

SUPERNUMERARY, something over and above a fixed number. In several of the offices are supernumerary clerks, to be ready on extraordinary occasions. There are also supernumerary surveyors of the excise, to be ready to supply vacancies when they fall; these have but half-pay.

SUPERSEDEAS, a writ that lies in a great many cases, and signifies, in general, a command to stay proceedings, on good cause shewn, which ought otherwise to proceed. By a *supersedeas*, the doing of a thing which might otherwise have been lawfully done, is prevented; or, a thing that has been done, is, notwithstanding it was done in a due course of law, thereby made void. A *supersedeas* is either expressed or implied; an express *supersedeas* is sometimes by writ, sometimes without writ; where it is by writ, some person to whom the writ is directed, is thereby commanded to forbear the doing something therein mentioned; or if the thing has been already done, to revoke, as that can be done, the act. A person can be superseded out of prison, when, by the practice of the court, the plaintiff has omitted to proceed in due time against him.

SUPPLEMENT OF AN ARC, in Geometry, is the number of degrees that it wants of being an entire semicircle: as complement signifies what an arc wants of being a quadrant. In Literature, supplement is an appendage to a book, which supplies what was deficient in it.

SUPPLICAVIT, in Law, a writ issuing out of the court of King's Bench, or Chancery, for taking surety of the peace, when one is in danger of being hurt in his body by another.

SUPPORTERS, in Heraldry, figures standing on the scroll, and placed by the side of the escutcheon, and seeming to support or hold up the same. They are sometimes human figures, and at other times animals, and creatures of the imagination.

SUPPURATION, in Surgery, denotes the process by which purulent matter is formed in cases of abscesses, ulcers, &c.

SUPPURATIVES, are medicines that ripen and promote suppuration.

SUPREMACY, in English polity, is the sovereignty of the king over the church as well as the state of which he is the established head. Among the Roman Catholics, this supremacy in all ecclesiastical matters is lodged in the pope.

SURA, the name of a liquor in the East Indies, made of the juice that is extracted from the cocoa-tree. It is, however, not held in very high estimation.

SURCINGLE, a girdle with which the clergy of the church tie their cassocks. It is also a girth that comes over the saddle, and binds it firmly to the horse.

SURD, in Arithmetic and Algebra, denotes any number or quantity that is incommensurable to unity, otherwise called an irrational number or quantity.

SURETY, in Law, generally signifies the same with bail.

SURETY of the Peace. A justice of the peace may, according to his discretion, bind all those to keep the peace, who in his presence shall make any affray, or shall threaten to kill or beat any person, or shall contend together in hot words; and all those who shall go about with unlawful weapons or attendance to the terror of the people; and all such person as shall be known by him to be common barrators; and all who shall be brought before him by a constable for a breach of the peace in the presence of such constable; and all such persons, who having been before bound to keep the peace, shall be convicted of having forfeited their recognizance. Lamb. 77.

SURETY of the good behaviour, includes the peace, and he that is bound to the good behaviour, is therein also bound to the peace; and yet a man may be compelled to find securities for the good behaviour and the peace.

SURE, the swell of the sea, which breaks upon the shore, or any rock lying near the surface, which renders such places dangerous.

SURFEIT, an indisposition occasioned by eating or drinking to excess, or overcharging the stomach. It is usually attended with eruptions, and sometimes with fever.

SURGERY, is the art of curing or alleviating diseases by local and external applications, manual or instrumental. As a

science, it may be defined, that department of maladies that susceptible of alleviation or cure.

SURNAM, a name added to the proper or baptismal name, to denominate the person of such a family. These hereditary names were first introduced by the Romans, on account of their league with the Sabines.

SURPLICE, the habit of the officiating clergy in the church of England.

SUR-REBUTTER, a second rebutter.

SUR-REJOINDER. As a rejoinder is the defendant's answer to the replication of the plaintiff, so a *sur-rejoinder* is the plaintiff's answer to the defendant's rejoinder.

SURRENDER, a deed or instrument testifying that the particular tenant of lands or tenements for life or years, does sufficiently consent and agree, that he who has the next or immediate remainder or reversion thereof, shall also have the present estate of the same in possession; and that he yields and gives up the same to him; for every surrenderer ought forthwith to give possession of the things surrendered.

SURROGATE, one who is substituted or appointed in the room of another; as the bishop or chancellor's surrogate.

SURSOLID, in Arithmetic, the fifth power of a number, or the fourth multiplication of any number considered as a root.

SURVEY, in Law, the ascertaining of the boundaries and royalties of a manor, or estate in lands, and also of the tenure of the respective tenants, and the rent and value of the estate.

SURVEYORS OF THE NAVY, two officers who sit at the navy board, being invested with the charge of building and repairing his majesty's ships at the different dock-yards of the kingdom; for which purpose they are trained to the theory and practice of ship-building.

SURVIVOR, in Law, signifies the longer liver of two joint tenants, or any two persons joined in the right of any thing.

SURVIVORSHIP. Payments which are not to be made till some future period, are termed *reversions*, to distinguish them from immediate payments. These being founded on contingencies, form a most intricate subject of calculation. Survivorship belongs only to those who survive other individuals, on the probable extent of whose lives the calculations are made, and the probable longevity of theirs who survive.

SUS, the *Hog*, in Natural History, a genus of mammalia, of the order bellua. These animals are allied by their teeth to the carnivorous quadrupeds, and by their cloven feet to the ruminating ones. They feed almost indifferently upon animal and vegetable substances, devouring with avidity what is most nauseous and disgusting. They use their snout in digging up the ground in quest of roots, are fond of rolling and wallowing in mud, and distinguished by extreme fecundity. There are six species, of which the following is the most important.—The common hog. All the varieties of this animal originate in the wild boar, which is found in most of the temperate regions of Europe and Asia. It is smaller than the domesticated animal, and uniformly of a dark gray colour, approaching to black. It is armed with formidable tusks, sometimes ten inches, or even more, in length; those in the under jaw curving inwards, and capable, from their size, strength, and sharpness, of inflicting the most dreadful wounds. Before these animals attain their third year, they are gregarious, and particularly when danger is at hand, they muster in numerous parties, and with great promptitude, at the signal of alarm. Uniting thus, they present so formidable an array, as speedily to disperse the enemy; few creatures, or none, daring to commence an attack against such a combination of strength and valour as they exhibit. When the wild boar is complete in growth, he depends upon his solitary exertions for his protection, is seldom seen in society, ranging the forests alone; rarely commencing an attack, as his food consists almost solely of roots and vegetables, but repelling one with all the fierceness of courage, and all the resentment of retaliation.—The *babaroussa*, is remarkable for the form and situation of the upper tusks, which are placed externally, and turn upwards in a curve towards the forehead. It abounds in the Indian islands, lives solely on vegetables, and rests itself, in sleep, by hooking its upper tusks round the branch of a tree. It can swim with rapidity, and is valued for food.—The Mexican hog, or *pecari*, is the only animal of the genus native of America, where it is

particularly if the diver attacks him there with all his power. For two swimmers, the labour is easier, because they can mutually relieve each other.

SWINE. See *Sus*.

SWIVEL, a small piece of artillery, carrying a shot of half a pound, and fixed in a socket on the top of a ship's side, stern, or bow, and also in the tops; the trunnions of this piece are contained in a sort of iron crotch, whose lower end terminates in a cylindrical pivot resting in the socket, so as to support the weight of the cannon. By means of this swivel (which gives name to the piece of artillery) and an iron handle on its cascabel, the gun may be directed by hand to any object. *Swivel* is also a strong link of iron used in mooring-chains, &c. which permits the bridges to be turned repeatedly round, as occasion requires.

SWORD. A weapon used either in cutting or thrusting; the usual weapon of fight hand to hand. It also signifies figuratively, destruction by war; as, fire and sword.

SYCAMORE, (*Acer Pseudoplatanus*.) the *Plane Tree* of Scotland, and *Ficus Sycamorus*, the *Egyptian Fig-tree*; both grow to a large size. The wood of the former is soft, white, and chiefly valued by turners.

SYLLABUB, a kind of compound drink, chiefly in demand during summer. It is ordinarily made of white wine and sugar, into which some new milk is thrown by a syringe. The ingredients, however, vary in different hands, as also the proportions of the articles used.

SYLLOGISM, in Logic, an argument or term of reasoning, consisting of three propositions; the two first of which are called premises, and the last the conclusion: as, Every creature possessed of reason and liberty, is accountable for his actions. Man is a creature possessed of reason and liberty; therefore man is accountable for his actions.

SYMBOL, a sign or representation of any moral subject by the images or properties of things natural. Thus, courage finds its symbol in the lion, parental affection in the pelican, &c. Among Christians, bread and wine are symbols of the body and blood of Christ.

SYMPATHY, an agreement of affections and inclinations, or a conformity of humours, temperaments, and natural qualities, which makes two persons pleased and delighted with each other. The various opinions that have been entertained respecting the power of sympathy, have led to many curious and romantic speculations.

SYMPHONY, in Music, properly denotes a consonance or concert of several sounds agreeable to the ear, whether vocal or instrumental, called also harmony.

SYMPTOM, in Medicine, denotes any change in the body or its functions, (perceptible either to an observer, or to the patient himself,) which indicates disease.

SYNAGOGUE, literally imports an assembly or congregation; but it is now restricted to a particular assembly of the Jews, met to perform the offices of their religious worship.

SYNCHRONISM, the happening of several things or events together, at or in the same time.

SYNCOPE, in Physiology, fainting.

SYNECDOCHE, in Rhetoric, a figure, in which the whole of a thing is put for a part of it only, or a part for a whole. This figure is of very considerable latitude; and is used, 1st, when the genus is put for the species; 2dly, when the species is put for the genus; 3dly, when the essential whole is put for one of its parts; 4thly, when the matter or form is put for the whole being; 5thly, the whole for a part; or lastly, the part for the whole.

SYNOD, in church history, is a council or meeting of ecclesiastics, to consult on matters of a religious nature.

SYNTAX, in Grammar, the proper construction or due disposition of the words of a language into sentences.

SYNTHESIS, in Logic, a method of pursuing truth by reasons drawn from pre-established principles, or propositions already proved, and thus proceeding by a regular chain, until we reach the conclusion.

SYPHON, On the more extensive Employment of the. The syphon, one of the most simple but at the same time interesting of hydraulic instruments, may be very considerably extended. We shall at present content ourselves with pointing out the ad-

vantage with which it may be applied to the conveyance of water to a distance over eminences, from a spring, well, &c. properly situated for the purpose. The usual methods of conveying water in such situations are either by cutting away the eminence to lay a pipe at a sufficient depth to obtain a fall, or by raising the water, by means of a pump, to a reservoir, and conveying it thence by a pipe to the situation required: both these methods we consider objectionable; the former, because of the great labour and expense attending the execution, besides the difficulty of getting to the pipe in case of a leak or stoppage; and the latter, on account of the original expense, the continual labour of pumping, liability of the pump to get out of repair, &c.

The syphon is liable to few or none of these objections; and the reason it has been so little employed is probably the difficulty or the expense of exhausting the air from out of the syphons on a large scale. To obviate this, may be adopted the following simple and easy method of setting any syphon to work, however large its dimensions, provided the perpendicular height of the shorter leg is not greater than the column of water capable of being raised by the pressure of the atmosphere. This method is not only simple, and easy to be repeated when necessary, but attended with so trifling an expense as must remove any objection on that score.

a a represents the surface of the ground, *b c d e*, a well, the depth of which we will suppose to be seven yards, and the depth of water one yard; *f* the situation where the water is wanted, the distance of which from the well is immaterial. *A A A*, the syphon; at the extremity of the shorter leg *B*, which is immersed in the water, is a valve opening upwards, and at the other extremity is a cock, which may either be a common one, or one with a ball, &c. according to circumstances: at the crown of the syphon, a pipe *C* is soldered to the highest part of the bend, for the purpose of filling the syphon with water, and which must be done gradually, to admit the air to escape as the water descends. When the syphon is quite filled with the water, the top of the pipe *C* must be made perfectly air-tight, by means of a screw-cap, with a collar of leather, or, if on a large scale, by means of a flange, with screw bolts and nuts, &c. When this is done, turn the cock at *f*, and the water will commence and continue a rapid stream, as long as any remains in the well. Great care must of course be taken that the pipe composing the syphon is good, and perfectly air-tight.

SYRINGE, an instrument so constructed as to imitate a quantity of any fluid, and to squirt or expel the same with violence. The uses to which the syringe has of late been applied, have rendered it so important, that for one invented by Mr. Read a patent has been obtained, and its vast utility renders it worthy of a particular description. In cases of swallowing poison, it has been so repeatedly and successfully tried, that no doubt can remain as to its intrinsic value. The apparatus consists of the pump, now generally known by the name of the "Stomach Pump," the œsophagus tube, three leathern tubes, and three ivory pipes, (which last, with the third leathern tube, is used only for enemas,) and a brass socket. The cylinder of the pump or syringe, (made in brass and in silver,) is about seven inches in length, and one inch in diameter, contracted at its apex into a small opening for receiving the extremity of an elastic tube, which is passed into the stomach. Within this opening is a chamber containing a spherical valve, which, by rising into the upper part of the chamber, where a vacuum is formed by elevating the piston, admits the fluid to pass freely into the syringe, but as soon as the piston is depressed, the contents of the syringe press the valve close upon the aperture,

and prevent its escape through the opening by which it was received. To give exit to the contents of the syringe, a side branch is constructed, furnished with a valved chamber, similar to the one above described, but so placed as to act in direct opposition to it, so that when the syringe has been filled from the extremity, and pressure is made by depressing the piston, the fluid closes the lower valve, and opens the lateral one, and

engraving. Figure A represents the operation of injecting fluids into the stomach, to dilute the poison previous to its extraction. This is effected in the following manner:—Screw the two first lengths of the leathern tube to the lateral branch of the syringe, and next the detached socket to the extremity of the former. The œsophagus tube is now to be passed through the mouth into the stomach, which being done, insert the brass joint at its extremity, into the socket at the end of the leathern tubes. The fluid to be injected, being put into a basin or other shallow vessel, the end of the syringe is immersed in it, and the piston being put into action, any quantity may be thrown into the stomach that shall be desired.

Emptying the Stomach.—A sufficient quantity of fluid having been injected into the stomach by the above process, the enema tube is to be withdrawn from the œsophagus tube, (without removing the former from the syringe, or the latter from the stomach,) and the joint of the œsophagus tube inserted into the extremity of the syringe; let an assistant now hold a vessel to the end of the enema tube, and by working the piston, the contents of the stomach may speedily be pumped into it, as shewn in figure B of the drawing. By thus transferring the end of the œsophagus tube from one situation to the other, the two processes of washing and emptying the stomach, may be repeated as often as is judged necessary by the operator. Thus it is seen that the syringe is furnished with two valvular apertures, through one of which the contents of the stomach pass into the cylinder, and are then immediately forced through the other into the receiving vessel. This double operation is effected by repeated strokes of the piston, which slides so easily, that an infant may use it. The manner in which the syringe is held in the two separate operations, is very important. In the first, as is seen in the engraving, a perpendicular position is the most eligible; but in the second, the syringe must be held in an inclined position, at about an angle of 45° , with the lateral tube upwards. These positions preserve the valves upon their proper bearings, without which the instrument cannot act perfectly.

A New Method of Operating with Read's Patent Syringe.—An improved mode of removing poison from the stomach with this instrument was first adopted in St. Thomas's Hospital, and has since been performed successfully in a variety of cases, as represented in the following sketch. *a*, a guard, to be introduced between the teeth, for protecting the œsophagus tube from injury.

This is by far the quickest, easiest, and most simple mode of operating that has hitherto been devised, requiring no shifting of the apparatus, nor interruptions of the operation. It consists

consequently escapes through the latter aperture. To facilitate the operation of the instrument, a small pipe communicates with the upper extremity of the syringe, which gives free ingress and egress to the atmosphere during the action of the piston, a circumstance essentially necessary in causing the instrument to work easily and perfectly. The operation of evacuating poison from the stomach, is represented in the annexed

simply in filling the stomach, (according to the method of fig. A, in the preceding engraving,) until surcharged, or until it begins to react upon its contents, when the fluid regurgitates by the mouth. The pumping being now continued, the contents of the stomach are washed up, and forced, by the power of the pump, through the œsophagus (by the side of the tube) into a vessel held under the chin to receive it. The operation may be continued as long as the surgeon thinks proper, or until the fluid returns unchanged, which indicates the thoroughly cleansed state of the stomach. The operator may occasionally suspend the action for an instant, if necessary, to allow the patient to inspire. By this means the fluid may be injected in the quantity of three quarts a minute.—But it is not merely to the extracting of poisons from the stomach that the use of the patent syringe is confined, as may be gathered from the following particulars.

Injecting the Bladder.—In cases of retention of urine, it frequently happens, that in consequence of hæmorrhage and other causes, the catheter becomes so obstructed that the bladder cannot be emptied. It was suggested to Mr. Scott by Dr. Cloquet, a celebrated surgeon of Paris, to effect this purpose by fixing a pump to the catheter. The patent syringe performs this operation with extreme facility, and has been honoured with the entire approbation of Dr. Cloquet. For injecting the bladder, which is an operation every day becoming more frequent, it is of course equally eligible. For these purposes, Mr. Read has constructed elastic gum catheters, to be fixed to the extremity of the enema tube: see *c* in the following engraving.

As an apparatus for conveying nourishment into the stomach of persons afflicted with stricture of the œsophagus, and stimulating liquids in cases of suspended animation, the patent syringe is found to possess obvious advantages.

Cupping and Drawing the Breasts.—This pump is also capable of being adjusted to cupping-glasses, by which any degree of

exhaustion can be made, that the operator desires; and in the same manner it may be rendered a very effectual instrument for drawing the breasts of puerperal females. Mr. Read has had glasses made for these uses, which may be obtained with the rest of the apparatus: see *f, g*, in the succeeding engraving.

Tobacco Fumigation and Enema Injection.—*Tobacco Fumigation.* Figure C in the first Plate, represents the syringe with a canister, for the purpose of injecting tobacco fumes into the intestines. It is used in the following manner: Unscrew the cap of the canister, and take out the perforated plunger; put in the tobacco (half an ounce, or an ounce) and replace the plunger lightly upon it; then put on the cap, and screw it to the end of the syringe; hold a lighted candle close under the bottom of the canister, and a stroke or two of the piston of the syringe will light the tobacco. The enema tubes being now fixed to the side branch, and the pipe introduced into the rectum, the tobacco-smoke is forced into the intestines as long as the syringe is worked in the usual manner.

Operation of administering Enemas.—We have lastly to speak of this syringe as an instrument for administering enemas, which was the original intention for which it was constructed, and in this point of view it is of the highest importance. On this subject Mr. Read has been favoured with the following remarks from the pen of Mr. Scott, and we gladly avail ourselves of his permission to insert them.

"The objects of administering enemas are considered to be of three kinds: 1st, For softening and diluting retained feces; 2ndly, For stimulating the bowels, and thus provoking evacuations; and, 3rdly, For producing mechanical distension. It must be obvious to every medical practitioner, how very inadequate the old apparatus of the pipe and bladder is to the completion of these objects; and thence it is that various instruments have been at different times devised, to remedy the deficiency; but ingenuity had been exercised in vain, and the profession were still in need of an instrument to effect these valuable ends, until the patent syringe supplied the desired means. It had hitherto been the custom of surgeons, in administering enemas, to throw up three-quarters of a pint, or a pint, of fluid; and a clyster, even in the severest cases, rarely exceeded the latter quantity. Now, by an attention to the anatomical structure of the lower intestines, it must be apparent that such a quantity would be incapable of effecting more than a mere solution of the feculent matter contained in the rectum, and of stimulating this bowel only; for the calibre of the rectum is so great, that, under ordinary circumstances, it can of itself contain a pint of fluid. Most commonly the cause of constipation exists in the colon; how then can the disease be relieved or removed by a clyster that is expended before it reaches this part of the canal? It will be urged, perhaps, that the superior bowels will be affected sympathetically, when the lower bowel is stimulated; but, granting this to be fact, how desirable is it to insure the good effects of an enema by administering a quantity sufficient to reach the offending part of the intestinal tube! But this could not be done by any of the existing instruments, as not one of them was of a size to contain a sufficient quantity of fluid; and, if they had been, it would have required a greater degree of power to force it into the bowels, than could have been conveniently or safely directed. I may, perhaps, be asked, why a large quantity could not be applied by recharging the instrument, or by discharging other instruments ready filled, and placed at hand for that purpose? I need not point out the fallacy of this argument to medical men, practically acquainted with the operation; for they are well aware of the difficulties which suspending the operation would present to the introduction of separate portions of fluid, as the *conatus ejiciendi* is generally so quickly excited, as to leave but a short interval between the injection and expulsion."

An instrument was therefore wanted, that was capable of throwing up any quantity desired, in one continuous operation, and the patent syringe most completely effects this. Again, mechanical distension can only be effected by an instrument affording power with volume; an attention to hydraulic principles shews how both these are yielded by the syringe that Mr. Read has constructed. The bulk of the fluid contained in the instrument is so small, that the force necessary to propel it scarcely requires the efforts of an infant; but the effects of these efforts, multiplied by repetition, increase to an almost infinite ratio, and at length present an overwhelming force, capable of bearing down all opposition, and overcoming all natural restraints. To try the power of the syringe, Mr. Read fixed the injecting pipe firmly into the rectum of an animal that had been recently killed, and proceeded to pump into the bowels a large quantity of water, and he continued the operation with the same ease and freedom, until the intestinal canal, stretched beyond its tone, burst with the distending force. In corroboration of the good effects of this instrument in obstructions of the bowels, we shall take leave to extract the following remarks from some of the most respectable medical publications of the present time.

"Dr. Chisholm has related a case of obstinate constipation of the bowels, relieved by Read's Injecting Machine, after various other means had failed. The obstruction had existed three or four days before Dr. Chisholm saw the patient with Mr. Beet, surgeon, of Ashford. When seen by Dr. Chisholm, the patient's extremities were cold, and stercoraceous vomiting had come on. A tepid solution of yellow soap was prepared, and more than a wash-hand basin full was gradually but perseveringly thrown up by means of the instrument above mentioned, and prevented from returning by napkins pressed to the anus. The patient's belly now resembled a drum. When the injection was allowed to come away, the spectators had the gratification to find it mixed with feces. Shortly after this, the patient passed flatus and stools, and all the bad symptoms quickly vanished. 'I have had many other cures,' says Dr. Chisholm, 'where Read's Machine was of infinite service, and I think every medical practitioner should have one of these instruments in his possession.'—*Med. Repository*, No. 1, new Series, page 944.

The author of *The Village Doctor*, under the article Costiveness, (page 104,) makes the following remark: "But the use of clysters is in every way preferable to purgative medicines, and those who are costive should provide themselves with Read's Patent Syringe, and administer a pint of the domestic enema every day at a certain hour, until the bowels act without."

The following remarks are to be seen in Dr. Johnson's Quarterly Review: "For many months past we have been in the habit of employing Mr. Read's Patent Injecting Apparatus, which is so small as to be carried in the waistcoat pocket, and so powerful as to throw fluids to a great distance. The object of our present notice, however, is to inform our readers that Mr. Read has adapted to the instrument a flexible elastic tube, most admirably calculated for throwing fluids into the stomach, and then extracting them in cases of poisoning. We have attentively examined the instrument, and we know it is approved of by Sir A. Cooper, and some of the first surgeons of the Metropolis; we think it of so much importance, that we seriously recommend it to every private practitioner."—*Vol. iv. No. 15, page 742, of the Medico-Chirurgical Review.*

In treating upon iliac passion, an author, before mentioned, says, "A copious injection of six or eight quarts of warm water, or gruel, will be the most likely means of removing the obstruction, restoring the bowels to their proper situation, and of softening and bringing away those hardened motions, which accumulate in the bowels, and occasion the complaint. For this purpose (as well as for the injection of tobacco smoke,) Read's patent syringe is preferable to all other instruments, and should be in the possession of every family."—*Scott's 'Village Doctor,' page 166.*

We are informed by some medical gentlemen who have used it, that in violent cases of menorrhagia, they have been able to check the disease more effectually by an alum injection thrown by the force which the patent syringe affords, than by any other means.

Directions for Using the Enema Apparatus.—We shall close our subject by the following explanation of the manner of using the enema apparatus:—Fix the enema tube to the lateral branch of the syringe, and put the fluid to be injected into a wash-hand basin, or other convenient vessel; the ivory pipe being inserted into the rectum, and the extremity of the syringe into the fluid, the pump may be worked, either by the patient or some other person; but the facility with which it can be accomplished by the former, by fixing the curved pipe to the tube, renders it truly valuable for domestic use.

The following extract of a letter, dated General Infirmary, Northampton, December 4, 1824, and addressed to Mr. Read, shows the practical utility of his invention:—"A boy, nine years of age, was discovered at eight o'clock in the morning of the 12th ult. in nearly a lifeless state. On investigation it was ascertained that he had taken, by mistake, a solution of opium three hours before. He was lying in a deep stupor, his respiration very slow, and accompanied with a convulsive catching; his feet, hands, and face livid, and no pulse to be felt at the wrist. He was immediately roused up, and violently shaken, when he uttered a few incoherent cries. A quart of warm water was instantly injected into the stomach by means of your syringe, and then withdrawn; the fluid was brown, and the smell of opium plainly perceptible. Another quantity of water was then thrown in, and withdrawn; it returned colourless, and without any smell.—The boy was now moved continually about for some time, and his senses gradually returned. As soon as he could swallow, he was made to drink two ounces of ipecacuanha wine, with a drachm of sulphate of zinc, dissolved in half a pint of warm water. This not operating, in twenty minutes a second dose was given as strong as the first, and in ten minutes afterwards the boy shewed a disposition to vomit: this was effectually excited by injecting a hand-basin full of warm water, by which I made sure that his stomach should be completely washed of any remains of the poison. After the vomiting was over, he was kept in motion three or four hours, taking at intervals a strong decoction of coffee: by the afternoon of the same day I had the pleasure of finding him perfectly well.—It is almost unnecessary to observe, that as the opium had been swallowed three hours, (and that too upon an empty stomach,) no emetic medicine would have operated until the poison was withdrawn, the fibres of the stomach being rendered perfectly inert by the stupefactive effect of the drug; indeed he had totally lost the power of swallowing; it is therefore pretty evident, that the boy's life would not have been saved, but for the very useful instrument of which you have the merit of being the inventor. I am, sir, with much respect, your obedient servant, CHARLES WITT, House Surgeon."

Approved, C. Bouverie, Chairman of the Committee.
SYRINGE, applied to Veterinary Practice.—"A righteous man regardeth the life of his beast." Proverbs, chap. xii. v. 10.—Fig. 1, a, enema tube for horses; b, ditto do. dogs; c, vessel containing the injecting fluid, Fig. 2, injecting apparatus for hoven or blown cattle; d, the oesophagus tube for bullocks; e, ditto do. sheep.

Animals, as well as man, are liable to accidents and disorders, that demand the aid of medical surgery; and among these, the occurrence of constipation and obstruction of the bowels, and of the fatal effects of excessive abdominal distension, from an undue quantity of improper food, frequently brings a most useful and highly valued animal into a situation of the utmost danger. Examples of the former are constantly experienced with horses and dogs. The former possesses a tendency to costiveness, from the dry nature of the food with which they are supplied, under the general routine practice of feeding; and they are rendered still more susceptible of this state, and consequently of obstruction and even inflammation, by protracted and heavy labour, and by neglect or improper management after severe exercise. It is also a well-ascertained fact, that the sports of the field induce a costive state of the bowels of dogs, that often reduce the animal's condition and health, and not unfrequently destroy his life. The attention of sportsmen and gentlemen cannot, therefore, be too seriously drawn to this subject; and we present to their consideration an instrument by which the lives of many valuable animals have been saved, when every other means had failed. By

means of the apparatus represented by fig. 1, enemas may be easily administered either to horses or dogs; and the instrument is such as to admit of any quantity being injected into

may be considered applicable to the size of the animal and to the nature of the case. The engraving, fig. 1, represents the action of the instrument; the tube being screwed to the side branch of the syringe, and the pipe introduced into the bowels, the extremity of the syringe is held in the fluid to be injected (which is put into a pail or other convenient vessel) and the piston being put into action, the clyster passes freely into the intestines. The facility afforded by this instrument, of drawing fluids into the bowels of animals, was demonstrated by an experiment performed at Charlton Mews, before Mr. Goodwin, his majesty's veterinary surgeon, in which Mr. Read injected a clyster of three gallons in two minutes.

The next consideration, as to the applicability of the instrument, is to the cases of hoven (or blown) cattle. The frequency of this occurrence to bullocks and sheep, from overgorging with potatoes, turnips, flax-seed, ground meal, green clover, or any moist or succulent food, is unfortunately well known to the agriculturist, and every person practically engaged in the breed and management of stock; and it has been often experienced, that the means generally resorted to in those cases are but too frequently ineffective. The failure may be accounted for by observing how inadequate either puncture in the loin, or the introduction of Monro's tube, is to the evacuation of the offending matter: if this were merely gas, either of the above means would probably liberate it; but it should be known that the stomach is filled by a fermenting pulsatious mixture of solid fluids, and gas, that cannot be discharged in the manner of gas simply. The patent syringe, before described, is found to be as exactly applicable for this as for any other purpose; and Mr. Read has prepared tubes to be fixed to it, either for sheep or bullocks, see plate d. e. Fig. 2, shews the operation of extracting the contents of the stomach of a blown bullock; the tube is passed into the stomach, and the syringe being fixed to it, and put into action, the offending matter is discharged at the side opening.

Horticultural and Domestic Uses of the Patent Syringe. Numerous and important as the uses of the patent syringe are in animal application, its utility is capable of a still further extension. For watering pines and all other plants in conservatories and hot-houses, and for the destruction of insects upon trees in forcing-houses or on walls, it far exceeds the barrow-engine in the facility of its application. The Horticultural Society of London, to mark their approbation of it, honoured the patentee by conferring upon him their silver medal for the invention. It has of late been much used for washing the windows of houses and carriages, and is found to be a most effective apparatus for fumigating trees and hot-houses.

This instrument also, in case of need, is an excellent fire-engine, as from its portability it can be applied to the first breaking out of a fire, when no sort of assistance could be derived

from the engines of the Insurance Companies, and its utility in this way having been proved by actual experience, most of the Fire Offices have prepared themselves with it, and it is now very properly finding its way into private families, as a safeguard against the destructive and hazardous effects of fire.

Having thus described the uses of this simple but valuable invention, we close the subject, with the following statement of the whole expense of the apparatus:—Price of the enema apparatus £2. 12s. 6d. and with the tobacco canister, £3. 3s.—Price of the poison apparatus, £3. 10s.—The catheter 6s.—The nipple glass 6s.—and the cupping glasses 6s. each.

SYRINGOTON, the name of an instrument to lay open the fistula.

SYRUP, an agreeable liquor or composition, of a thick consistence, made of juices, tinctures, or waters, of fruits, flowers, or herbs, boiled up with sugar or honey, in order to preserve the compound from spoiling by fermentation, or otherwise. Syrups furnish an almost endless variety.

SYSTEM, in general denotes an assemblage or chain of principles and conclusion; or the whole of any doctrine, the several parts whereof are bound together, and depend on each other.

SYTHE, the subject of the Hainault sythe having excited considerable interest, we present our readers with an engraving, and an account of it extracted from the Farmer's Magazine of August, 1825. This instrument was brought under the notice of the Directors of the Highland Society of Scotland so far back as June, 1823. The summer general meeting passed over, and no funds could be voted to defray the necessary expense of trial that season; the directors could only recommend to the members and their friends, who might travel in Flanders during the then ensuing harvest, to obtain information respecting it on the spot; and, with a view to the ulterior proceedings contemplated, the deputy-secretary was directed to procure two of the sythes. Many of our readers must have heard of the trials made several years ago with the Hainault sythe on the farm of Modiford, near Christchurch, belonging to Sir George H. Rose. This gentleman had employed a Flemish labourer, a prisoner of war, to teach his people the use of it; and some of them, it appears, had acquired great proficiency, and were able to instruct others. The first experiments were reported in the newspapers, and attracted a good deal of notice at the time; and yet it does not appear that this had the effect of introducing it into general use even in that neighbourhood. Whatever may have been the cause of this, it is certain, that its comparative merits were neither unknown nor unappreciated in other quarters. Mr. Warden, Sir George's bailiff, after this gentleman had let his farm, on being appointed to the embassy at Berlin, had instructed the reapers of Colonel Hughes, near St. Asaph, and those of 'Sir Watkin W. Wynne, at Wynnestay. It appears also, from recent information, that the Hainault sythe, if not in common use, is at least well known in different parts of Wales, as well as of England, and that it was tried some time back as far north as Aberdeenshire. The directors of the Highland Society were not ignorant of all this; but, knowing the difficulties which a new implement has to encounter before it can be subjected to a sufficient number of well-conducted experiments to have its merits decided on,—difficulties which could not fail to be increased by this being a foreign implement, and probably often used by unskilful hands,—they resolved, notwithstanding, to put the question at rest by having it tried in a variety of situations, and with the different kinds of crops; and that these trials should not be confined to one or two districts, but made throughout most of the corn counties of Scotland, under the inspection of the local agricultural societies. Such an arrangement, it is evident, was well calculated to make the merits of the implement extensively known, and, at the same time, to afford an opportunity to the labourers of almost every part of Scotland to learn how to work with it. Through the kind offices of M. the Chevalier Masclet, consul of France, two hands, the sons of small farmers, were engaged in French Flanders, and brought over at the expense of the society. They arrived at Edinburgh on the 12th of July; on the 15th, they were employed in reaping with the Hainault sythe on the farm of Lochend, belonging to Mr. Oliver, in the neighbourhood of the city, before a great concourse of spectators; and the day

following they set out on the route assigned them by the society, through East Lothian, and the counties of Berwick and Roxburgh, practising one or two days near the principal towns. On the 22d they were at Dalkeith, from whence they were to proceed to Lanarkshire, Renfrewshire, the Carse of Stirling and Gowrie, and the counties of Fife, Forfar, Aberdeen, and Moray, and perhaps still farther north, if the duration of the harvest will admit of it. The members of the Highland Society, abounding in every part of Scotland, and most of them at this season, in the country, engaged to attend the trials in the several districts; while the local agricultural societies entered into the measure with a degree of spirit and liberality, (having offered, of their own accord, to relieve the Highland Society from part of the general expense,) which have not often been equalled, and which are to be found, to the same extent, and among the same class, in no other country than Britain. Still further to insure accurate and full reports, the Highland Society circulated printed queries, to direct the attention of those who attend the trials to the most important circumstances.

The following is the result of experiments made in East Lothian, Berwickshire, and Roxburghshire, that is, in the best cultivated counties in Scotland, in the following terms: "On the 16th and 17th, the use of the instrument was exhibited on the farm of Amisfield Maids near Haddington, in presence of the Marquis of Tweeddale, the Earl of Lauderdale, Mr. Hay of Spot, Mr. Hunter of Thurston, Mr. Balfour of Whittinghame, Mr. Rennie of Phantassie, Mr. Bogge of Woodhall, and many of the most eminent agriculturists in East Lothian; and we have been favoured by an intelligent spectator with the following account, accompanied by a few remarks:

"The first trial was made upon a field of strong wheat, and in two hours and a half the reapers cut down about a quarter of a Scots acre, though they were somewhat interrupted with stones. This trial satisfied the gentlemen present, that where land is free of stones, two reapers with the Hainault sythe might cut an acre of strong corn in a day, and that it will be cut closer, and with as little loss in shaking, as with the common sickle. On the second day the reapers cut some barley and oats; and though the superiority of the implement was not so evident as on the first occasion, (the corn being much lighter on the ground,) it was on the whole very satisfactory. They finished by another trial in the wheat field.

"There appeared some difference of opinion as to the advantage of using this implement on all occasions, but there is only one opinion as to its decided superiority in cutting strong standing corn. Care must be taken, however, to clear the land of stones; and where this is done, the crop will be cut closer, and as clean, with the Hainault sythe, as it can be by the modes practised in this country, and at considerably less expense.

"On the evening of the 17th, the party proceeded to Dunse; and next day exhibited, in a field of barley belonging to Mr. Logan, of Crumstain, in the presence of General Maitland, Mr. Hay, of Dunse Castle, and a number of the most respectable farmers in the neighbourhood. The barley was a heavy crop; and in an hour the two reapers cut 606 square yards, equal to one-eighth of an English acre, or at the rate of one acre three-eighths in a day of eleven hours. Those who witnessed the work stated, that it would require five of their best Irish reapers to cut the same quantity in the same time. The trial gave great satisfaction, and several gentlemen took immediate steps to enable some of their workmen to employ the sythe.

"Having arrived at Kelso on the evening of the 18th, arrangements were made for a short trial the next day, to suit the convenience of farmers attending the market; whilst Saturday, the 20th, was set apart for putting the abilities of the reapers to a full and fair test. Accordingly, on Friday afternoon, the use of the instrument was exhibited for about an hour, on Mr. Dudgeon's farm of Spylaw, to a very great concourse of spectators, all of whom appeared to take a most lively interest in the scene, and to derive much satisfaction from it. Next day the reapers were again upon the same ground about ten o'clock, and proceeded to work an hour on a very heavy crop of barley. They cut 726 square yards, which, on a day's work of ten hours, is at the rate of three-fourths of an English acre to each reaper. The ground was rather stony, and some impediment from the crowd was unavoidably sustained, otherwise, as asserted by the

reapers, they would have done at the rate of an acre each at least. At first several binders tied and set up the sheaves; afterwards one man undertook the task, and performed it: but he declared he could not have gone on throughout the day, and it was evidently too much for one of the best workers to accomplish.

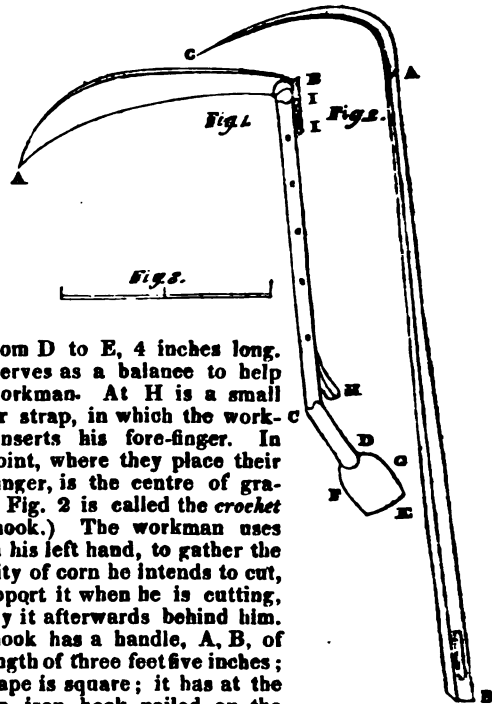

"The next trial took place upon some very light oats, and it certainly proved that the sythe was quite effectual on crops of that description, a fact which was very generally doubted. As there happened to be no wheat ready for cutting on Spylaw, the next and third trial was made upon a field of wheat near Kelso; a very fair crop, and the ground free from large stones. The day being far spent, the time was limited to a quarter of an hour, and the result was 212 yards, or at the rate of one acre and three-fourths, English measure, per day of ten working hours; and here again the obstructions from the crowd were very considerable. The whole corn taken down was cut closer to the ground, and cleaner, than by the sickle. Three of the best reapers with the sickle, cut an English acre per day, making also bands for the sheaves; but five are often found scarcely equal to the same work.

"These experiments were witnessed by a committee of the Highland Society, a Committee of the Union Agricultural Society, and a number of proprietors and eminent agriculturists; and at intervals a number of intelligent and active workers, who had been brought forward for the purpose, were allowed to use the sythes, and received instructions from the Flemings; and many of them shewed considerable expertness.

"The two young Flemings are sons of farmers in French Flanders, (where farms seldom much exceed 100 acres,) and their names are J. H. Dupre, and Luis Cattoeau, the first from the neighbourhood of Douay, the other from near Lille. Their behaviour is modest and unassuming; they are very intelligent, and shew a most praiseworthy anxiety for information, particularly in statistical and agricultural matters, on which they take numerous notes. They allege they cannot do so much work as the labourers in their own country, who depend solely for subsistence on their daily toil. To a question pointedly put to them, if the sythe could be used with advantage when the crop was on an acclivity? they unhesitatingly replied, 'Equally well as on a level piece of ground;' and offered to prove it."

Description of the Plate. This implement, called in England the Hainault sythe, is known in French Flanders under the name of *Piquet*, or *Petite Faulx*, (small sythe.) It is composed of two

parts, fig. 1 and 2. Fig 1 represents the piquet. The blade A to B, is 21 inches long and 2½ inches broad. The back is of an inch thick. The blade is fixed into the handle by one or rather two wedges I, I. The handle from I to C is seventeen inches long. At C it is curved; the length from C D, 6½ inches. The part F, G, E, is, from F to G, 3½ inches wide,

and from D to E, 4 inches long.

This serves as a balance to help the workman. At H is a small leather strap, in which the workman inserts his fore-finger.

In this point, where they place their fore finger, is the centre of gravity. Fig. 2 is called the *crochet* (the hook.)

The workman uses it with his left hand, to gather the quantity of corn he intends to cut, to support it when he is cutting, and lay it afterwards behind him.

This hook has a handle, A, B, of the length of three feet five inches; its shape is square; it has at the top an iron hook nailed on the wood: its length from A to C is 10½ inches.

The small opening above B is for the purpose of inserting the blade, so as to prevent the workman being hurt when carrying his implement.

T.

T A B

T, the nineteenth letter of our alphabet. In Abbreviations, amongst the Roman writers, T. stands for Titus, Titius, &c. Tab. for Tabularius; Tab. P. H. C. for Tabularius provincie Hispanie citerioris; Tar. Tarquinius; Ti. Tiberius; Ti. F. Tiberii filius; Ti. L. Tiberii libertus; Ti. N. Tiberius Nepos; T. J. A. V. P. V. D. tempora judicem arbitrumve postulat ut det; T. M. P. terminum posuit; T. M. D. terminum dedicavit; Tr. trans. tribunus; Tr. M. or Mil. tribunus militum; T. R. P. L. D. E. S. triannus plebis designatus; T. R. A. E. R. tribunus ærarii; T. V. R. C. A. P. triumviri capitales; T. R. or TRIB. POT. tribunicia potestata; Tul. H. Tulus Hostilius.

TABBY, in Commerce, a kind of rich silk which has undergone the operation of tabbying; or being passed through a calender, the rolls of which are made of iron or copper, variously engraven; which bearing unequally on the stuff, renders the surface unequal, so as to reflect the rays of light differently, making the representation of waves thereon.

TABLE, in Perspective, denotes a plane surface, supposed to be transparent, and perpendicular to the horizon. It is always imagined to be placed at a certain distance between the

T A C

eye and the objects, for the objects to be represented thereon by means of the visual rays passing from every point thereof through the table to the eye; whence it is called perspective plane.

TABLE, among the Jewellers. A table-diamond, or other precious stone, is that whose upper surface is quite flat, and the only sides cut in angles; in which sense, a diamond cut table-wise, is used in opposition to a rose-diamond.

TABLE, in Mathematics, systems of numbers calculated to be ready at hand for the expediting astronomical, geometrical, and other operations: thus, we say tables of the stars; tables of sines, tangents, and secants; tables of logarithms, rhumbs, &c.; sexagenary tables.

TABLING, a sort of broad hem, formed on the heads, skirts, and bottoms of a ship's sails, to strengthen them in that part which is attached to the bolt-rope.

TACCA, a genus of the class and order hexandria monogynia.

TACHYGRAPHY, the art of writing fast, or of short hand; of which authors have invented several methods.

TACK, a rope used to confine the foremost lower corners of

the courses and stay-sails, in a fixed position, when the wind crosses the ship's course obliquely. The same name is also given to the rope employed to pull out the lower corner of a studding-sail to the extremity of its boom. The main-sail and fore-sail of a ship are furnished with a tack on each side, which is formed of a thick rope, tapering to the end, and having a knot wrought upon the largest end, by which it is firmly retained in the clew of the sail; the tack therefore extends the sail to windward, while the sheet extends it to leeward.

TACK, is also applied, by analogy, to that part of any sail to which the tack is usually fastened. A ship is said to be on the starboard or larboard tack, when she is close-hauled with the wind on the starboard or larboard side, and in this sense the distance she sails in that position is considered as the length of the tack, although this is more frequently called a board. *To Tack*, to change the course from one board to another, or turn the ship about from the starboard to the larboard tack, or *vice versa*, in a contrary wind. It is performed by turning the ship's prow suddenly to the wind, whereby her head-sails being thrown aback, they receive the impression of the wind in a new direction, and cause her to fall off from the wind to the other tack.

TACKING, is also used in a more enlarged sense, to imply that manœuvre by which a ship makes an oblique progression to windward, in a zig-zag direction; this, however, is more usually called beating or turning to windward. The operation of tacking is thus performed: the helm being put to the lee-side, the commanding-officer calls out, 'Helm a-lee;' the head-sails are immediately made to shiver in the wind, by casting loose their sheets and bow-lines; the officer then calls, 'Raise tacks and sheets,' which is executed by loosening all the ropes which confine the corners of the lower sails, in order that they may be more readily shifted to the other side. When the ship has turned her head directly to the wind, the order is given to turn about the sails on the mizzen-mast, by the exclamation, 'Haul main-sail, haul;' the bow-lines and braces are then instantly let go on one side, and as expeditiously drawn in on the other side, so as to wheel the yards about their masts; the lower corner of the main-sail is, by means of its tack, pulled down to its station at the chess-tree, and the after-sails are at the same time adjusted to stand upon the other board. Finally, when the ship has fallen off five or six points, the commanding-officer calls, 'Haul off all,' or, 'Let go and haul;' then the sails on the foremast are wheeled about by their braces, and as the ship has a tendency to fall off, she is checked by the effort of the helm, which is for that purpose shifted to the now lee-side. The fore-tack, or lower corner of the foresail, being fixed in its place, the bowlines are hauled, and the other sails are properly arranged to the wind, which is called trimming all sharp. In order to explain the theory of tacking a ship, it may be necessary to premise a known axiom in natural philosophy, that every body will persevere in a state of rest, or of moving uniformly in a right line, unless it be compelled to change its state by forces impressed, and that the change of motion is proportional to the moving force impressed, and is made according to the right line in which that force is exerted. By this principle it is easy to conceive how a ship is compelled to turn in any direction by the force of the wind acting upon her sails in horizontal lines. For the sails may be so arranged as to receive the current of air either directly, or more or less obliquely; hence the motion communicated to the sails must of necessity conspire with that of the wind upon their surfaces. To make the ship tack, or turn round with her head to the windward, it is therefore necessary, after she has received the first impression from the helm, that the head-sails should be so disposed as to diminish the effort of the wind, in the first instant of her motion, and that the whole force of the wind should be exerted on the after-sails, which, operating on the ship's stem, carries it round like a weathercock. But since the action of the after-sails to turn the ship will unavoidably cease when her head points to the windward, it then becomes necessary to use the head-sails to prevent her from falling off, and returning to her former situation. These are accordingly laid aback on the lee-side, to push the vessel's forepart towards the appointed side till she has fallen into the line of her course thereon, and fixed her sails to conform with that situation.

TACKLE, a machine formed by the communication of a rope with an assemblage of blocks, and known in mechanics by the name of pulley. Tackles are used in a ship to raise, remove, or secure weighty bodies, to support the masts, or to extend the sails and rigging; they are moveable, as communicating with a runner, or fixed, as being hooked in an immovable situation; and they are more or less complicated in proportion to the effects which they are intended to produce. The application of the tackle to mechanical purposes is called hoisting or bousing. *Ground Tackle*, implies the anchors, cables, &c. *Tack Tackle*, a small tackle used to pull down the tacks of the principal sails to their respective stations, and particularly attached to the main-sails of brigs, sloops, cutters, and schooners. For various other tackles, see their particular epithets.

TACTICS, in the art of War, is the method of disposing forces to the best advantage in order of battle, and of performing the several military motions and evolutions.

TÆNIA, in Natural History, *Tape Worm*. Gmelin has enumerated almost one hundred species, besides varieties: he has divided them into sections. A. Those found in other parts besides the intestines, and furnished with a vesicle behind. B. Those found in the intestines only, and without a terminal vesicle. C. Those with the head unarmed with hooks. The worms of the first section are found infesting mammalia, reptiles, and fish. Those of the second section are found in the mammalia, in birds, and in fish; and those of the third section infest mammalia, birds, reptiles, and fish. This genus of worms are destined to feed on the juices of various animals, and are usually found in the alimentary canal, generally at the upper part of it. They are sometimes found in great numbers, and occasion the most distressing disorders. They have the power of reproducing parts which have been broken off, and are therefore removed with the utmost difficulty: they are oviparous, and discharge their eggs from the apertures on the joints.

TAFFAREL, the uppermost part of a ship's stern, being a curved piece of wood, and usually ornamented with some device in sculpture.

TAIL OF A GALE, a name given by sailors to the latter part of a storm, wherein its violence is considerably abated.

TAIL-Block, a single block, having a short piece of rope attached to it, by which it may be fastened to any object at pleasure, either for conveyance, or to increase the force applied to the said object.

TAKING-IN, among Seamen, the act of brailing up and furling the sails at sea, particularly when the wind increases; and is generally used in opposition to setting.

TALC, in Mineralogy, a stone, the characters of which are, a specific gravity between 3.5834 and 2.9902; a texture easy to be scraped with the knife; a soft and unctuous surface; the primitive form of a right rhomboidal prism, its bases having angles of 120 degrees and 60 degrees, and in which sections parallel with these bases are easily obtained. Its integrant molecule has the same form.

TALENT, a money of account amongst the ancients, equal to £342 sterling. Among the Jews, a talent in weight was equal to 60 maneh, or 113 pounds, 10 ounces, 1 pennyweight, 10 and two-seventh grains.

TALES is used in Law, for a supply of men impannelled on a jury, and not appearing, or on their appearance challenged and disallowed, when the judge, upon motion, orders a supply to be made by the sheriff of one or more such persons present in court, to make up a full jury.

TALLOW, animal fat melted down and clarified; but the name is frequently given to this unctuous substance in its most simple state. After domestic purposes are supplied, the great consumption is in the making of soap and candles, and in the dressing of leather.

TALLOW Tree. In China this tree grows in great abundance. It is about the height of a pear tree, and in habit it resembles that of the cherry. The seeds, which are numerous, are separated from the white substance in which they are enclosed, by being steeped ten or fifteen days in water; after which, being put into a press, a glutinous oil drops from them, which soon hardens into the consistence of animal tallow. The seed is also sometimes hoiled in water, when the oil is found floating on its surface. Candles made of this substance are very white, and,

according to Sir George Staunton, are firmer than those of common tallow, as well as free from all offensive odour; but he thinks them inferior to such as are made of wax or spermaceti. The Chinese frequently colour this tallow with vermilion, to add to its beauty.

TALLY, a piece of wood, on which retailers cut notches to mark the goods delivered out on credit. Tallies are taken as evidence in courts of justice, as much as books.

TALLYING-AFT, a phrase applied to the act of pulling aft the sheets or lower corners of the main-sail and fore-sail.

TALMUD, or **THALMUD**, among the Jews, a collection of the doctrines of their religion or morality.

TALPA, the **MOLE**, a genus of quadrupeds of the order *feræ*. The common mole is about six inches in length, without the tail. Its body is large and cylindrical, and its snout strong and cartilaginous. Its skin is of extraordinary thickness, and covered with a fur, short, but yielding to that of no other animal in fineness. It hears with particular acuteness, and, notwithstanding the popular opinion to the contrary, possesses eyes, which it is stated to be able to withdraw or project at pleasure. It lives partly on the roots of vegetables, but principally on animal food, such as worms and insects, and is extremely voracious and fierce. Shaw relates, from Sir Thomas Brown, that a mole, a toad, and a serpent, have been repeatedly enclosed in a large glass vase, and that the mole has not only killed the others, but has devoured a very considerable part of them. It abounds in soft ground, in which it can dig with ease, and which furnishes it with the greatest supply of food. It forms its subterranean apartments with great facility, by its snout and feet, and with a very judicious reference to escape and comfort. It produces four or five young in the spring, in a nest a little beneath the surface, composed of moss and herbage. It is an animal injurious to the grounds of the farmer, by throwing up innumerable hills of mould, in the construction of its habitation, or the pursuit of its food; and many persons obtain their subsistence from the premiums which are, on this account, given for their destruction. Moles can swim with considerable dexterity, and are thus furnished with the means of escape in those sudden inundations to which they are frequently exposed. In Ireland, the mole is unknown.

TAMARICK, a large shrub much used in some parts in making quickset hedges. The French sort is chiefly used.

TAMARINDUS, the *Tamarind Tree*, a genus of plants arranged by Linnaeus under the class of triandria and order of monogynia. The timber of the tamarind tree is heavy, firm, and hard; sawn into boards, it is converted to many useful purposes in building. The fruit is used both in food and medicine. In many parts of America, particularly in Curaçoa, they eat abundance of it raw, without any inconvenience. In Martinico also, they eat the unripe fruit, even of the most austere kind.

TAMBAC, a mixture of gold and copper, which the people of Siam hold more beautiful and valuable than gold itself.

TAMBOUR, in Architecture, a term applied to the Corinthian and Composite capitals.

TAMBOUR, in the Arts, is a species of embroidery, in which threads of gold, silver, and silk, are formed into leaves, flowers, or other figures.

TAMPING, in Mining, is the clay, or other matter, rammed into a hole made in a rock, for blasting with gunpowder.

TAMPION, or **TOMPION**, a stopple or plug which closes up a hole in a vessel. In Gunnery, it is a wooden cylinder put into the muzzles of cannon, &c. to prevent the dust or wet from entering.

TAN, the bark of the oak chopped and ground in a tanning mill into a coarse powder, to be used in the tanning of leather.

TANGENT, in Geometry, is defined, in general, to be a right line, which touches any arch of a curve, in such a manner that no right line can be drawn betwixt the right line and the arch.

TANNIN. This, which is one of the immediate principles of vegetables, was first distinguished by Seguin from the gallic acid, with which it had been confounded under the name of the astringent principle. He gave it the name of tannin, from its use in the tanning of leather, which it effects by its characteristic property, that of forming with gelatin a tough insoluble matter.

TANNING. The several kinds of leather are prepared from the skins of animals, macerated for a long time with lime and water, to promote the separation of the hair and wool, and of the fat and fleshy parts, in which recourse is also had to the assistance of mechanical pressure, scraping, and the like. The skin, when thus deprived of its moist putrescible part, and brought considerably toward the state of mere fibre, is tanned by maceration with certain astringent substances, particularly the bark of the oak tree.—The hide consists almost wholly of gelatin, and all that is necessary is, to divest it of the hair, epidermis, and any flesh or fat adhering to it. This is commonly done, after they have been soaked in water some time, and handled or trodden to cleanse them from filth, by immersing them in milk of lime. Some, instead of lime, use an acescent infusion of barley or rye meal, or spent tan; and others recommend water acidulated with sulphuric acid. Similar acidulous waters are afterwards employed for raising or swelling the hide, when this is necessary. The skins thus prepared, are finally to undergo what is properly called the tanning. This is usually done by throwing into a pit, or cistern, made in the ground, a quantity of ground oak bark that has already been used, and on this the skins and fresh bark in alternate layers, covering the whole with half a foot of tan, and treading it well down. The tanning may be accelerated by adding a little water.

TANTALITE, a metallic fossil. Colour between bluish-grey and blackish-grey. Surface smooth, with some lustre. Luster metallic. Fracture compact. Streak blackish grey, approaching brown. Very hard. Not magnetic. Specific gravity 7.66. Composed of the oxides of tantalum, iron, and manganese.

TANTALUS, the *Ibis*, in Natural History, a genus of birds of the order *grallæ*. There are nineteen species, of which we shall notice the following. *T. loculator*, the wood ibis, is the size of a goose, and the *T. ibis* or the Egyptian ibis, is more than three feet long, and as large as a stork. On the retreating of the Nile, it is found in Lower Egypt in great numbers, subsisting on insects and frogs. It perches on palm trees, and stands in an erect attitude, its tail touching its legs. It is supposed by some naturalists to be the ibis of the ancients, and is known to destroy and devour serpents.

TAPESTRY, a kind of woven hangings of wool and silk, frequently raised and enriched with gold and silver, representing figures of men, animals, landscapes, histories, &c.

TAPIR, the name of an animal found in some parts of America. In size, it is about that of a stout calf, and in shape bears some resemblance to a hog.

TAPPING, the act of piercing a tree or barrel, to extract its juices or liquor. In Surgery, it is an operation performed on dropsical persons.

TAR, a thick, black, unctuous substance, obtained from old pines and fir trees by burning them with a smothering heat.

TAR, a kind of liquid gum, which is procured from pine or fir-trees, and is used to pay the sides of ships and boats, and their rigging and yards, in order to preserve them from the effects of the weather.

TARANTULA, a species of spider, the bite of which is extremely difficult to cure; and, even after a cure has been effected, the patient has usually some annual affection, from the latent poison of the insect.

TARE, in Agriculture, a plant of the vetch kind, of which there are two sorts.

TARE, is an allowance for the outside package that contains such goods as cannot be unpacked without detriment; or for the papers, threads, bands, &c. that enclose or bind any goods imported loose; or though imported in casks, chests, &c. yet cannot be unpacked and weighed net.

TARGIONIA, a genus of plants of the class of cryptogamia, and natural order of algae.

TARGUM, a name whereby the Jews call the Chaldee paraphrases or expositions of the Old Testament, in the Chaldee language.

TARIFF, a table or catalogue usually drawn in an alphabetical order, containing the names, and amount of duties paid on several kinds of merchandise.

TARPAWLING, a broad piece of canvass, well damped with tar, and used to cover the hatchways of a ship at sea, to

prevent the penetration of the rain or sea-water, which may at times rush over the decks.

TARRAS, or TERRAS. A volcanic earth used as a cement. It does not differ much in its principles from puzzolana; but it is much more compact, hard, porous, and spongy. It is generally of a whitish-yellow colour, and contains mere heterogeneous particles, as spar, quartz, spherul, &c. and something more of a calcareous earth. It effervesces with acids, is magnetic, and fusible *per se*. When pulverized, it serves as a cement, like puzzolana. It is found in Germany and Sweden. See **LIME**.

TARTAN, a small coasting vessel navigated in the Mediterranean sea, and having only one mast and a bowsprit, the principal sail, which is very large, being extended by a lateen yard.

TARTAR, or, according to the new chemistry, *tartrat of potass*, is obtained in a state of impurity, incrusting on the bottom and sides of casks in which wine has been kept. It is afterwards purified by dissolving it in boiling water, and filtering it while hot. On cooling, it deposits the pure salt in very irregular crystals. In this state it is sold under the name of crystals or cream of tartar.

TARTARIC ACID. Scheele was the first who obtained this acid in a separate state. He communicated his process for obtaining it to Retzius, who published it in the Stockholm Transactions for 1770. It consisted in boiling tartar with lime, and in decomposing the tartrat of lime thus formed by means of sulphuric acid. The process employed at present for obtaining tartaric acid, which is the same with that of scheele, is the following:—Dissolve tartar in boiling water, and add to the solution powdered chalk till all effervescence ceases, and the liquid ceases to redden vegetable blues. Let the liquid cool, and then pass it through a filtre. A quantity of tartrat of lime (which is an insoluble white powder) remains upon the filtre. Put this tartrat, previously well washed, into a glass cucurbit, and pour on it a quantity of sulphuric acid equal to the weight of the chalk employed, which must be diluted with water. Allow it to digest for twelve hours, stirring it occasionally. The sulphuric acid displaces the tartaric; sulphat of lime remains at the bottom, while the tartaric acid is dissolved in the liquid part. Decant off this last, and try whether it contains any sulphuric acid; this is done by dropping in a little acetat of lead; a precipitate appears which is insoluble in acetic acid, if sulphuric acid is present, but soluble if it is absent. If sulphuric acid is present, the liquid must be digested again on some more tartrat of lime; if not, it is to be slowly evaporated, and about one-third part of the weight of the tartar employed is obtained of crystallized tartaric acid.

TARTRATS, salts formed with the tartaric acid.

TASTE, a sensation excited by means of the organs of this sense, the papillæ of the tongue, &c. Taste is also used in a figurative manner for the judgment and discernment of the mind.

TAUGHT, the state of being extended or stretched out, and is usually applied in opposition to slack.

TAUGHT Sail, implies a great quantity of set sail.

TAUNT, an epithet, at sea, signifying high or tall. It is particularly expressed of the masts, when they are of an extraordinary length, as square is applied to the yards on the same occasion.

TAURUS, the Bull γ , is the second of the spring signs, and the sun enters it, according to the fixed zodiac of Hipparchus, on the 30th of April; but reckoning by the moveable zodiac, or the recession of the equinoxes, the transit takes place about the 12th of May. The earth is now in Scorpio, and the Sun as seen from the earth appears in Taurus, the north pole comes now more into the light, and the days increase as the nights decrease in length, at all places N of the Equator. On the 5th of May the earth is in the 15th degree of Scorpio, and the sun as seen from the earth appears in the 16th degree of Taurus. The tropic of Cancer is now in the light from a little after 5 o'clock in the morning, till about 7 in the evening; the parallel of London, from half an hour past 4, till half an hour past 7; the polar circle from 3 till 9; and a large tract round the N pole has day all the 24 hours, for many rotations of the earth on its axis. The Hyades and Pleiades, though denominated constellations, are integral parts of Taurus.

Boundaries and Contents.—N. by Perseus and Auriga; E. by Geminus; S. by Orion and Eridanus; and W. by Arcturus. There are 141 stars in this constellation.

TAUTOLOGY, a needless repetition of the same sense in different words.

TAWING, the art of dressing the skins of sheep, lamb, kid, and goats, in white, for divers manufactures, particularly gloves.

TAX, an impost laid by government on almost every thing.

TAXUS, in Botany, *Yew Tree*, a genus of the diœcia monodelphia class and order. Natural order of coniferae. The yew-tree is a native of Europe, North America, and Japan; its proper situation is in mountainous woods, or more particularly the clefts of high calcareous rocks. England formerly possessed great abundance, and it is now not very uncommon in a wild state, in some parts of the country. Of planted trees there are yet several in church-yards.

TEA, a valuable shrub, that abounds in China and Japan. Its leaves only are imported into Europe, the infusion of which is too well known to require any particular description. The difference in the qualities of tea is generally thought to arise from the season in which the leaves are gathered, and the manner in which they are preserved. The consumption of this article, in England alone, is almost incredible.

TEAK, a valuable timber which abounds in various parts of the East Indies, and is applied to domestic and nautical purposes. Ships built with teak are far more durable in the Indian seas than those made of English oak.

TEAL, the smallest species of bird of the duck kind.

TEAM, the number of horses, oxen, or other animals, united together to draw a cart, waggon, or other carriage.

TEASEL, a species of plant much used in cloth manufactories, for raising the nap on the article made. It is much cultivated in those districts, but in others it is considered as a weed, and destroyed.

TECHNICAL, expresses somewhat relating to arts and sciences; in this sense we say technical terms. It is also particularly applied to a kind of verses wherein are contained the rules or precepts of any art, thus digested to help the memory to retain them.

TEETH. The basis of the substance that forms the teeth, like that of other bones, appears to be phosphate of lime. The enamel, however, according to Mr. Hatchett, differs from other bony substances in being destitute of cartilage; for raspings of enamel, when macerated in diluted acids, he found were wholly dissolved; while raspings of bone, treated in the same manner, always left a cartilaginous substance untouched.

TELEGRAPH, is the name very properly given to an instrument, by means of which information may be almost instantaneously conveyed to a considerable distance. The telegraph, though it has been generally known and used by the moderns only for a few years, is by no means a modern invention. There is reason to believe that amongst the Greeks there was some sort of telegraph in use. A Greek play begins with a scene, in which a watchman descends from the top of a tower in Greece, and gives the information that Troy was taken: "I have been looking out these ten years (says he) to see when that would happen, and this night it is done." Of the antiquity of a mode of conveying intelligence quickly to a great distance, this is certainly a proof. The Chinese, when they send couriers on the great canal, or when any great man travels there, make signals by fire from one day's journey to another, to have every thing prepared; and most of the barbarous nations used formerly to give the alarm of war by fires lighted on the hills or rising grounds. Polybius calls the different instruments, used by the ancients for communicating information, fire-signals.

A new method, invented by Cleoxenus, (others say Democritus,) and very much improved by Polybius, as he himself informs us, is as follows: Take the letters of the (Greek) alphabet, and divide them into five parts, each of which will consist of five letters, except the last division, which will have only four. Let these be fixed on a board in five columns. The man who is to give the signals, is then to begin by holding up two torches, which he is to keep aloft till the other party has also shewn two. This is only to shew that both sides are ready. These first torches are then withdrawn. Both parties are provided with boards, on which the letters are disposed as formerly

described. The person, then, who gives the signal, is to hold up torches on the left, to point out to the other party from what column he shall take the letters as they are pointed out to him. If it is to be from the first column, he holds up one torch; if from the second, two; and so on for the others. He is then to hold up torches on the right, to denote the particular letter of the column that is to be taken. All this must have been agreed on beforehand. The man who gives the signals must have an instrument consisting of two tubes, and so placed as that, by looking through one of them, he can see only the right side, and through the other only the left, of him whom he is to answer. The board must be set up near this instrument; and the station on the right and left must be surrounded with a wall ten feet broad, and about the height of a man, that the torches raised above it may give a clear and strong light, and that when taken down they may be completely concealed. Let us now suppose that this information is to be communicated—*A number of the auxiliaries, about a hundred, have gone over to the enemy.* In the first place, words must be chosen that will convey the information in the fewest letters possible; as, *A hundred Cretans have deserted, Κρετες εκατον ἀφ' ἡμῶν προσημολοσαν.* Having written down this sentence, it is conveyed in this manner: The first letter is a K, which is in the second column; two torches are therefore to be raised on the left hand, to inform the person who receives the signals to look into that particular column. Then five torches are to be held up on the right, to mark the letter h, which is the left in the column. Then four torches are to be held up on the left, to point out the ρ (r), which is in the fourth column, and two on the right, to shew that it is the second letter of that column. The other letters are pointed out in the same manner. Such was the *pyrsia* or telegraph recommended by Polybius.—But neither this, nor any other method mentioned by the ancients, seems ever to have been brought into general use; nor does it appear, that the moderns had thought of such a machine as a telegraph till the year 1683, when the Marquis of Worcester, in his *Century of Inventions*, affirmed that he had discovered “a method by which, at a window, as far as eye can discover black from white, a man may hold discourse with his correspondent, without noise made or notice taken; being, according to occasion given, or means afforded, *ex re nata*, and no need of provision beforehand; though much better if foreseen, and course taken by mutual consent of parties.” This could be done only by means of a telegraph, which, in the next sentence, is declared to have been rendered so perfect, that by means of it the correspondence could be carried on “by night as well as by day, though as dark as pitch is black.”

Dr. Hooke, whose genius as a mechanical inventor was perhaps never surpassed, delivered a “Discourse to the Royal Society, May 21, 1684, shewing a way how to communicate one's mind at distances,” of 30, 40, 100, 120, &c. miles, “in as short a time almost as a man can write what he would have sent.” He takes to his aid the then recent invention of the telescope, and explains the method by which characters exposed at one station may be rendered plain and distinguishable at the others. He directs, “First, for the stations; if they be far distant, it will be necessary that they should be high, and lie exposed to the sky; that there be no higher hill, or part of the earth beyond them, that may hinder the distinctness of the characters that are to appear dark, the sky beyond them appearing white; by which means also the thick and vaporous air near the ground will be passed over and avoided.” “Next, the height of the stations is advantageous, upon the account of the refractions or inflections of the air.” “Next, in choosing of these stations, care must be taken, as near as may be, that there be no hill that interposes between them, that is almost high enough to touch the visible ray; because in such cases the refraction of the air of that hill will be very apt to disturb the clear appearance of the object.” “The next thing to be considered is, what telescopes will be necessary for such stations.” “One of these telescopes must be fixed at each extreme station, and two of them in each intermediate; so that a man for each glass, sitting and looking through them, may plainly discover what is done in the next adjoining station, and with his pen write down on paper the characters there exposed in their due order; so that there ought to be two persons at each extreme station, and three at each

intermediate; so that, at the same time, intelligence may be conveyed forwards and backwards.” “Next, there must be certain times agreed on, when the correspondents are to expect; or else there must be set at the top of the pole, in the morning, the hour appointed by either of the correspondents for setting that day: if the hour be appointed, pendulum clocks may adjust the moment of expectation and observing.” “Next, there must be a convenient apparatus of characters, whereby to communicate any thing with great ease, distinctness, and secrecy. And those must be either day characters or night characters.” The day characters “may all be made of three slit deals;” the night characters “may be made with links, or other lights, disposed in a certain order.” The doctor invented twenty-four simple characters, each constituted of right lines, for the letters of the alphabet; and several single characters, made up of semicircles, for whole sentences. He recommended, that three very long masts or poles should be placed vertically, and joined at top by one strong horizontal beam; that a large screen should be placed at one of the upper corners of this frame, behind which all the deal-board characters should hang, and by the help of proper cords should quickly be drawn forwards to be exposed, and then drawn back again behind the screen. “By these means,” says the doctor, “all things may be made so convenient, that the same character may be seen at Paris, within a minute after it hath been exposed at London, and the like in proportion for greater distances; and that the characters may be exposed so quick after one another, that a composer shall not much exceed the exposor in swiftness.” Among the uses of this contrivance, the inventor specifies these: “The first is for cities or towns besieged; and the second for ships upon the seas; in both which cases it may be practised with great certainty, security, and expedition.” The whole of Dr. Hooke's paper was published in Derham's collection of his *Experiments and Observations*; from which it appears, that he had brought the telegraph to a state of far greater maturity and perfection than M. Amonton's, who attempted the same thing about the year 1702; and indeed to a state little inferior to several which have been proposed during the last twenty years.

During the French revolution the telegraph was applied to useful purposes. Whether M. Chappe, who is said to have invented the telegraph first used by the French about the end of 1793, knew any thing of Hooke's or of Amonton's invention, it is impossible to say; but his telegraph was constructed on principles nearly similar. The manner of using this telegraph was as follows:—At the first station, which was on the roof of the palace of the Louvre at Paris, M. Chappe, the inventor, received in writing, from the committee of public safety, the words to be sent to Lisle, near which the French army at that time was. An upright post was erected on the Louvre, at the top of which were two transverse arms, moveable in all directions by a single piece of mechanism, and with inconceivable rapidity. He invented a number of positions for these arms, which stood as signs for the letters of the alphabet; and these, for the greater celerity and simplicity, he reduced in number as much as possible. The grammarian will easily conceive, that sixteen signs may amply supply all the letters of the alphabet, since some letters may be omitted, not only without detriment, but with advantage. These signs, as they were arbitrary, could be changed every week, so that the sign of B for one day might be the sign of M the next; and it was only necessary that the persons at the extremities should know the key. The intermediate operators were only instructed generally in these sixteen signals; which were so distinct, so marked, so different the one from the other, that they were easily remembered. The construction of the machine was such, that each signal was uniformly given in precisely the same manner at all times: it did not depend on the operator's manual skill; and the position of the arm could never, for any one signal, be a degree higher or a degree lower, its movement being regulated mechanically. M. Chappe having received at the Louvre the sentence to be conveyed, gave a known signal to the second station, which was Mont Martre, to prepare. At each station there was a watch-tower, where telescopes were fixed, and the person on watch gave the signal of preparation which he had received, and this communicated successively through all the line, which brought

them all into a state of readiness. The person at Mont Martre then received, letter by letter, the sentence from the Louvre, which he repeated with his own machine; and this was again repeated from the next height, with inconceivable rapidity, to the final station at Lille.

Two working models of this instrument were executed at Frankfort, and sent by Mr. W. Playfair to the Duke of York; and hence the plan and alphabet of the machine came to England, where various experiments were in consequence tried upon telegraphs, and one was soon after set up by government in a chain of stations from the Admiralty-office to the sea-coast. It consists of six octagon boards,* each of which is poised upon an axis in a frame, in such a manner that it can be either placed vertically, so as to appear with its full size to the observer at the nearest station, as in fig. 1, or it becomes invisible to him by being placed horizontally, as in fig. 2, so that the narrow edge alone is exposed, which narrow edge is from a distance invisible. Fig. 2 is a representation of this telegraph with the parts all shut and the machine ready to work. T, in the officer's cabin, is the telescope pointed to the next station. Fig. 2, is a representation of the machine not at work, and with the ports all open.

The opening of the first port (fig. 1,) expresses *a*, the second *b*, the third *c*, the fourth *d*, the fifth *e*, and the sixth *f*, &c. Six boards make 36 changes, by the most plain and simple mode of working; and they will make many more, if more were necessary; but as the real superiority of the telegraph over all other modes of making signals consists in its making letters, we do not think that more changes than the letters of the alphabet, and the ten arithmetical ciphers, are necessary; but, on the contrary, that those who work the telegraphs should avoid communicating by words or signs agreed upon to express sentences; for that is the sure method never to become expert at sending unexpected intelligence accurately. Several other telegraphs have been proposed to remedy the defects to which the instrument is still liable. The dial-plate of a clock would make an excellent telegraph, as it might exhibit 144 signs so as to be visible at a great distance. A telegraph on this principle, with only six divisions instead of twelve, would be simple and cheap and might be raised 20 or 30 feet high above the building, without any difficulty; it might be supported on one post, and therefore turn round, and the contrast of colours would always be the same.

A very ingenious improvement of the telegraph has been proposed in the Gentleman's Magazine; it consists of a semicircle to be properly elevated, and fixed perpendicularly on a strong stand. The radius 12 feet; the semicircle consequently somewhat more than 36. This is to be divided into 24 parts. Each of these will therefore comprise a space of 18 inches, and an arch of $7^{\circ} 30'$ on the circumference. These 24 divisions to be occupied by as many circular apertures of six inches diameter; which will leave a clear space of six inches on each

side between the apertures. These apertures beginning from the left, to denote the letters of the alphabet, omitting *K*, *J*, consonant, *V*, *X*, and *Q*, as useless for this purpose. There are then 21 letters. The four other spaces are reserved for signals.

The instrument to have an index moveable by a windlass on the centre of the semicircle, and having two tops, according as it is to be used in the day or night; one, a circular top of lacquered iron or copper, of equal diameters with the apertures (and which consequently will eclipse any of them against which it rests); the other a spear or arrow-shaped top, black, and highly polished, which in standing before any of the apertures in the day-time will be distinctly visible. In the night, the apertures to be reduced by a diaphragm sitting close to each so as to leave an aperture of not more than two inches diameter. The diaphragm to be of well-polished tin; the inner rim lacquered black half an inch. All the apertures to be illuminated, when the instrument is used in the night-time, by small lamps; to which, if necessary according to circumstances, convex lenses may be added, fitted into each diaphragm, by which the light may be powerfully concentrated and increased. Over each aperture one of the five prismatic colours least likely to be mistaken (the remaining two being less distinguishable, and not wanted, are best omitted) to be painted; and, in their natural order, on a width of eighteen inches and a depth of four, red, orange, yellow, green, blue; or, still to heighten the contrast, and render immediately successive apertures more distinguishable, red, green, orange, blue, yellow. The whole inner circle beneath and between the apertures to be painted black.

When the instrument is to be used, the index to be set to the signal apertures on the right. All the apertures to be covered or dark when it begins to be used, except that which is to give the signal. A signal gun to be fired, to apprise the observer. If the index is set to the first aperture, it will denote that words are to be expressed; if to the second, that figures; if to the third, that the figures cease; and that the intelligence is carried on in words. When figures are to be expressed, the alternate apertures from the left are taken in their order, to denote from 1 to 10 inclusively; the second from the right denotes 100; the fifth 1000. This order, and these intervals, are taken, to prevent any confusion in so peculiarly important an article of the intelligence to be conveyed.

Perhaps, however, few of the telegraphs hitherto offered to the public exceed the preceding, either in its simplicity, cheapness, or facility in working; and it might, perhaps, with a few trifling additions, be made exceedingly distinct. It is thus described in the *Repertory of Arts and Manufactures*. For a nocturnal telegraph let there be four large patent reflectors, lying on the same plane, parallel to the horizon, placed on the top of

* The form is now altered, and a single pole with moveable arms conveys intelligence.

an observatory. Let each of these reflectors be capable, by means of two winches, either of elevation or depression to a certain degree. By elevating or depressing one or two of the reflectors, eighteen very distinct arrangements may be produced, as the preceding scheme will explain.

For the sake of example, the above arrangements are made to answer to the most necessary letters of the alphabet; but alterations may be made at will, and a greater number of changes produced, without any addition to the reflectors. In the first observatory there need only be a set of single reflectors; but in the other, each reflector should be double, so as to face both the preceding and subsequent observatory; and each observatory should be furnished with two telescopes. The proper diameter of the reflectors and their distance from each other will be ascertained by experience; and it must be observed, that each reflector, after every arrangement, must be restored to its place. To convert this machine into a diurnal telegraph, nothing more is necessary, than to insert in the place of the reflectors, gilt balls, or any other conspicuous bodies.—Since these inventions were made public, telegraphs have been brought to so great a degree of perfection, that they now convey information speedily and distinctly, and are so much simplified that they can be constructed and maintained at little expense.

The advantages, too, which result from their use, are almost inconceivable. Not to speak of the speed with which information is communicated and orders given in time of war, by means of them, the whole kingdom could be prepared in an instant to oppose an invading enemy. A telegraph might also be used by commercial men to convey a commission cheaper and speedier than an express can travel. An establishment of telegraphs might be made like that of the post; and instead of being an expense, it would produce a revenue. Something of this kind was about ten years ago set up, to facilitate the intercourse between Norwich and Yarmouth.—*Dr. Gregory's Mechanics.*

TELESCOPE. Under the article OPTICS, the character, use, and power of this valuable instrument, have been introduced to the reader's notice. We shall now advert to two remarkably constructed telescopes,—that of Fraunhofer, and that of Dollond. The great discovery of a method of making flint glass in large pieces, and perfectly pure and free from striae, which was made by the late M. Guinand, may be considered as forming an era in the history of the achromatic telescope. By means of this glass, M. Fraunhofer, the director of the Optical Institute or manufactory at Benedictbaur, near Munich, has constructed achromatic telescopes far superior to any that have hitherto been made; and we have been assured, that this eminent artist can now make achromatic object-glasses with an aperture of eighteen inches. But it is not merely in the optical part of the instrument that M. Fraunhofer has been successful. His various improvements on the apparatus which accompanies the telescope, and his ingenious micrometers for measuring angles of all kinds in the heavens, have received the sanction of some of the most eminent practical astronomers in Europe, and are now considered as constituting an instrument of incalculable value for general astronomical observations. In this splendid telescope, made for the observatory of Dorpat, the hour-circle is divided by two verniers into four seconds of time, and the declination circle into ten seconds. The equatorial axis is put in motion by a clock having two sets of wheel-work, so that the telescope follows by itself the diurnal motion of the stars. But it may also be turned freely by the hand in every direction, or by means of an endless screw. The friction of the equatorial axis is diminished by friction rollers, so that the telescope, though its weight was about thirty-six quintals of Bavaria, could be moved by the pressure of a single finger. The object-glass is thirteen and one-third feet (Pied de Ro de Paris) in focal length, and its aperture is nine inches. It has eight astronomical eye-pieces, beside the following micrometers:—1. A repeating line micrometer, with a circle of position, whose two verniers give a single minute. This micrometer is furnished with a mechanism for illuminating the lines, the field remaining obscure, so that these lines appear to be luminous stripes on a dark ground. These lines are cut upon glass with a diamond point. As these lines appear like so many silver threads suspended in the heavens, the transits of the smallest stars across them may be observed. 2. Two micrometers, each of which consists of two

free rings. 3. Two micrometers with one free ring. In all these micrometers, the rings, which are accurately turned out of brass, are fixed upon plates of glass, so that they seem to be suspended in the field of the telescope. By observing the immersions and emersions of the stars at the inner and outer circumferences of the rings, the differences of right ascension and declination of two stars are determined. 4. A micrometer of several concentric rings, which may be illuminated in the dark field. This micrometer has four eye-glasses. 5. An achromatic finder, of thirty inches in focal length, and twenty-nine of aperture. An instrument for correcting the axis of the great object-glass.—The price of the telescope now described is about 8000 Prussian dollars, or nearly £1300 sterling. The total weight of the whole package is thirty-eight quintals. An achromatic telescope with an object-glass eighteen feet in focal length, and with an aperture of twelve inches, and furnished with eye-glasses, micrometers, and paraflectic stand, like the one now described, amounts to about £1720 sterling. Mr Fraunhofer engages likewise to construct these instruments with object-glass eighteen inches in diameter: and, as the price increases nearly as the cube of the diameter, an instrument of this kind will cost about £9200 sterling.

Dollond's Achromatic Telescope.—Fig. 6, No. 1, in the plate, represents the telescope, supported in the centre of gravity, with its rack-work motions, and mounted on its mahogany stand, the three legs of which are made to close up together by means of the brass frame *a a a*, which is composed of three bars connected together in the centre piece by three joints, and also to the three legs of the mahogany stand by three other joints, so that the three bars of this frame may lie close against the insides of the legs of the mahogany stand, when they are pressed together for convenience of carriage. The brass pin, under the rack-work, is made to move round in the brass socket *b*, and may be tightened by means of the finger-screw *d*, when the telescope is directed nearly to the object intended to be observed. This socket turns on two centres, by which means it may be set perpendicular to the horizon, or to any angle required in respect to the horizon; the angle may be ascertained by the divided arc, and then made fast by the screw *e*. If this socket be set to the latitude of the place at which the telescope is used, and the plane of this arc be turned on the top of the mahogany stand, so as to be in the plane of the meridian, the socket *b* being fixed to the inclination of the pole of the earth, the telescope, when turned in this socket, will have an equatorial motion, which is always very convenient in making astronomical observations.

No. 2, in the plate, represents a stand to be used on a table, which may be more convenient for many situations than the large mahogany stand. The telescope, with its rack-work, may be applied to either of the two stands, as occasion may require, the sockets on the top of both being made exactly of the same size. The sliding rods may be applied to the feet of the brass stand, so that the telescope may be used with the same advantages on one as on the other. The tube *A A* may be made either of brass or mahogany, of three and half feet long. The achromatic object-glass of three and half feet focal distance has an aperture of two inches and three quarters. The larger size is with a tube five feet long, and has an achromatic object-glass of three inches and one quarter aperture. The eye tube, as represented by *B*, contains four eye-glasses to be used for day, or any land, objects. There are three eye tubes, as *C*, which have two glasses in each to be used for astronomical purposes. These eye tubes all screw into the short brass tube at *D*. By turning the button or milled head at *f*, this tube is moved out of the larger so as to adjust the eye-glasses to the proper distance from the object-glass, to render the object distinct to any sight with any of the different eye tubes. The magnifying power of the three and half feet telescope with the eye tube for land objects is forty-five times, and of the five feet, for land objects, sixty-five times; with those for astronomical purposes, with the three and half feet the magnifying powers are eighty, one hundred and thirty, and one hundred and eighty; and for the five feet one hundred and ten, one hundred and ninety, and two hundred and fifty-times. Stained glasses, as *g*, are applied to all the different eye tubes, to guard the eye in observing the spots on the sun. These are to be taken off when the eye tubes are used

for other purposes. The rack-work is intended to move the telescope in any direction required, and is worked by means of the two handles at A. When the direction of the tube is required to be considerably altered, the worm screws which act against the arc, and the circle must be discharged; then the screw d, being loosened, the pin of the rack-work will move easily round in the socket d.

For the more readily finding or directing the telescope to any object, particularly astronomical objects, there is a small tube or telescope, called the finder, fixed near the eye-end of the large telescope. At the focus of the object-glass of this finder there are two wires, which intersect each other in the axis of the tube, and as the magnifying power is only about six times, the real field of view is very large; therefore any object will be readily found within it, which being brought to the intersection of the wires, it will then be within the field of the telescope.—In viewing astronomical objects, (and particularly when the greatest magnifying powers are applied,) it is very necessary to render the telescope as steady as possible; for that purpose there are two sets of brass sliding rods, i, i, as represented in the plate. These rods connect the eye-end of the telescope with two of the legs of the stand, by which any vibration of the tube, that might be occasioned by the motion of the air, or otherwise, will be prevented, and the telescope rendered sufficiently steady for using the greatest powers. These sliding rods move within one another, with so much ease as to admit of the rack-work being used in the same manner as if they were not applied.

Herschel's Telescope.—This wonderful instrument was begun at Clayhill in 1785, and afterwards, with all its apparatus, removed to Slough, near Windsor, where it was completed under the fostering patronage of royal munificence. The foundation on which the frame-work is erected, consists of two concentric circles of brickwork, so constructed, that the machinery may be turned so as to bring the point of the tube against any part of the heavens. The whole fabric is supported on twelve rollers, of which six are seen (IIII) in the drawing. On each side of the elevated end of the tube is a double ladder, and at the opposite extremity is another. Several other smaller ones are seen in different parts, but their uses are too obvious to need either reference or description. The transverse beam H H, which is stretched horizontally over the crossings of the ladders, is bolted to them, and receives the books of different pulleys G G, as seen in the drawing. The ropes connected with these pulleys are moved by machinery, near the bottom. Below the mouth of the large tube is a gallery, C B, so constructed as to be elevated or depressed according to the situation of the tube. This furnishes gratification to the spectator, and enables the astronomer who views the heavens, to have access to the extremity of the tube whenever his presence may be required. The cabin D, of which the window is visible, affords shelter to those within, who, through the telescope, watch the motions of the heavenly bodies. The smaller cabin under the tube, is connected with the apparatus.—The tube of the telescope, which is 32 feet 4 inches long, and 4 feet 10 inches in diameter, is made entirely of iron, it having been ascertained that one of wood would exceed the iron one in weight by at least 3000 lb. The sheets were first put together by a kind of seaming that required no rivets, and when the sides of the iron platform were cut straight, it was lifted into a hollow gutter, and then brought gradually into a cylindrical form. Within the tube various hoops are fixed, some of which are connected by longitudinal bars of iron that are attached to the two ends of the tube. These are introduced, to brace the sheets, and keep the shape perfect, when the pulleys are applied to give the necessary elevation at the upper end, and that the speculum might be kept secure in its bed at the lower extremity. Its proportionate degrees of strength have been calculated with great care, so that at A no depression takes place. The lower end of the tube, which the cabin D renders invisible, is firmly supported on rollers that move forward or backward by the rackwork seen at E. The large speculum is enclosed in a strong iron ring, braced across with bars of iron, while an enclosure of iron and tin sheets makes a case for it. When necessity requires, it is lifted by three iron handles attached to the sides of the ring, and is taken from

and returned to its place by a moveable crane that runs on a carriage. See OPTICS.

TELESCOPIUM, the Telescope, situated south of the Centaur Sagittarius, and contains nine small stars, one of which is of the fourth magnitude, the rest being less in size.

TELESCOPIUM HERSCHELI. Herschel's telescope is a new asterism, which has been inserted in honour of the astronomer of that name.—Boundaries and Contents: N. and E. by Lynx, E. and S. by the Twins, and W. by Auriga; right ascension 95°, declination 40° N. About 17 stars have been assigned to this constellation, from the 5th magnitude to the 8th.

TELLER, an officer of the exchequer, in ancient records called tallier; there are four of these officers, whose duty is to receive all sums due to the king, and to give the clerk of the pells a bill to charge him therewith.

TELL-TALE, on ship-board, a small piece of wood, traversing in a groove across the front of the poop deck, and which, by communicating with a small barrel on the axis of the steering wheel, indicates the situation of the helm.

TEMPERATURE, in general, denotes that degree of free caloric which a body appears to possess when compared with other bodies. Sir Humphrey Davy defines temperature to be "the power bodies possess of communicating or receiving heat, or the energy of repulsion." This definition, however, seems to have nothing but the celebrity of his name to recommend it.

TEMPERING, of steel and iron, the rendering of them either more compact and hard, or soft and pliant, according as the different uses for which they are wanted may require.

TEMPLARS, or TEMPLERS, a religious order instituted at Jerusalem, about the year 1118. Some religious gentlemen put themselves under the government of the patriarch of Jerusalem, renounced property, made the vow of celibacy and obedience, and lived like canons regular. King Baldwin assigned them an apartment in his palace. They had likewise lands given them by the king, the patriarch, and the nobility, for their maintenance. They took the name of knights templars, because their first house stood near the temple dedicated to our Saviour at Jerusalem. This order having performed many great exploits against the infidels, became rich and powerful all over Europe; but the knights abusing their wealth and credit, fell into great disorders and irregularities. Many crimes and enormities being alleged against them, they were prosecuted in France, Italy, and Spain; and at last the pope, by his bull of the 22d of May, 1312, given in the council of Vienna, pronounced the extinction of the order of Templars, and united their estates to the order of St. John of Jerusalem.

TEMPLE, a public building erected in honour of some deity, either true or false, and in which people meet to pay religious worship to the same.

TENACITY, a term applied to metals, by which is meant the power that a metallic wire of a given diameter has of resisting, without breaking, the action of a weight suspended from its extremity.

TENANT, signifies one who holds or possesses lands or tenements by any kind of right, either in fee, for life, years, or at will.

TENDER, in Law, is an offer to pay a debt or perform a duty. This is often pleaded in an action as a bar to the plaintiff's recovery; and where the money demanded by the plaintiff has been tendered or offered to him before the commencement of the suit, and he has refused to accept it, the plaintiff is barred of his action and costs.

TENDER, a small vessel employed to attend a larger one, to supply her with stores, to carry intelligence, &c. Vessels appointed to receive volunteers and impressed men, and to carry them to receiving ships, &c. are also called tenders.

TENDING, the movement by which a ship turns or swings round, when at single anchor, or moored by the head, in a tide-way, at every change of tide.

TENDONS, are white, firm, and tenacious parts, continuous to the muscles, and usually forming their extremities.

TENEMENT, in its original, proper, and legal sense, signifies every thing that may be holden, provided it is of a permanent nature, whether it is of a substantial or unsubstantial and ideal kind.

TENNIS, a play at which a ball is driven by a racket.

TENON, in Bruiding, &c. the square end of a piece of wood, or metal, terminated by one-third of its thickness, to be received into a hole in another piece, called a mortise, for joining or securing the two together.

TENSE, tense, in Grammar, an inflection of verbs, whereby they are made to signify or distinguish the circumstance of time in what they affirm.

TENSION, the state of a thing stretched.

TENT, in Surgery, a roll of lint worked into the shape of a cone, with a broad flat head.

TENTER, a raising used in cloth manufacture, to stretch out the pieces of cloth, stuff, &c. or only to make them even, and set them square. It is usually about four feet and a half high, and for length exceeds that of the longest piece of cloth. It consists of several long pieces of wood, placed so that the lower even-piece of wood may be raised or lowered, as is found requisite, to be fixed at any height by means of pins. Along the pieces, both the upper and under one, are hooked nails, called tenter-hooks, driven in from space to space.

TENURE, the manner whereby lands or tenements are holden, or the service that the tenant owes to his lord.

TEREDOS, in Natural History, the ship-worm, a genus of the vermes testacea class and order. There are three species. The shell of this worm is very thin, cylindrical, and smooth; found on the sides and bottoms of ships, and the stoutest oak pales which have remained some time under water: it was imported from India. The destruction which these worms effect under water is almost equal to that of the termites, or white ant, on land. The shell is more or less twisted, rather obtuse at the tip, and from four to six inches long. They will appear, on a very little consideration, to be the most important beings in the great chain of creation, and a pleasing demonstration of the infinitely wise and gracious power which formed and still preserves the whole in such wonderful order and beauty; for if it was not for the rapacity of these and such animals, tropical rivers, and indeed the ocean itself, would be choked with the bodies of trees annually carried down by the rapid torrents, as many of them would last for ages, and probably be productive of evils, of which happily we cannot in the present harmonious state of things form any idea; whereas now, being consumed by these animals, they are more easily broken in pieces by the waves; and the fragments which are devoured become specifically lighter, and are consequently more readily and more effectually thrown on shore, where the sun, wind, insects, and various other instruments, speedily promote their entire dissolution.

TERIM, in Geometry, is the extreme of any magnitude, or that which bounds or limits its extent.

TERMS, are those spaces of time wherein the courts of justice are open for all that complain of wrongs or injuries, and seek their rights by course of law or action, in order to their redress; and during which the courts in Westminster hall sit and give judgments, &c. but the high court of parliament, the chancery, and inferior courts, do not observe the terms; only the court of King's Bench, Common Pleas, and Exchequer, the highest courts at common law. Of these terms there are four in every year: viz. Hilary term, which begins the 23d of January, and ends the 12th of February, unless on Sundays, and the day after; Easter term, which begins the Wednesday fortnight after Easter-day, and ends the Monday next after Ascension-day; Trinity term, which begins on the Friday after Trinity Sunday, and ends the Wednesday-fortnight after; and Michaelmas term, which begins the 6th and ends the 28th of November.

TERMS, Irish, are the same as those of London, except that at Michaelmas, which commences October 13, and adjourns to the beginning of November.

TERMS, Oxford. Hilary or Lent term begins on January 14, and ends on the Saturday before Palm Sunday. Easter term begins the tenth day after Easter, and ends the Thursday before Whit-Sunday. Trinity term begins the Wednesday after Trinity Sunday, and ends after the act, sooner or later, as the vice-chancellor and convocation please. Michaelmas term begins on Oct. 10, and ends Dec. 17.

TERMS, Cambridge. Lent term begins on Jan. 13, and ends the Friday before Palm Sunday. Easter term begins the Wed-

nesday after Easter week, and ends the week before Whit-Sunday. Trinity term begins the Wednesday after Trinity Sunday, and ends the Friday after the commencement. Michaelmas term begins Oct. 10, and ends Dec. 16.

TERMS, Scotland. In Scotland, Candlemas term begins Jan. 23, and ends Feb. 12. Whitsontide term begins May 25, and ends June 15. Lammas term begins July 30, and ends August 5. Martinmas term begins Nov. 3, and ends Nov. 21.

TERMES, or **AST**, in Natural History, a genus of insects of the order aptera. The white ant is given in the Philosophical Transactions, of which we shall notice a few particulars. These insects are inhabitants of East India, Africa, and South America. They build pyramidal structures ten or twelve feet in height, and divided into appropriate apartments, magazines for provisions, arched chambers, and galleries of communication. These are so firmly cemented, that they easily bear four men to stand upon them, and in the plains of Senegal appear like the villages of the natives. With such wonderful dexterity and rapidity they destroy food, furniture, books, clothes, and timber of whatever magnitude, leaving a mere thin surface, that in a few hours a large beam will be eaten to a mere shell as thick as writing paper. These only are the labourers who build the structures, procure provisions for the males and females, and take care of the eggs; they are the most numerous. Another class, called pupa, are larger, about half an inch long, with a very large ovate polished testaceous head. These never work, but act as superintendants over the labourers, or as guards to defend their habitations from intrusion and violence. When a breach is made in the dwelling, they rush forward, and defend the entrance with great ferocity; some of them beating with their mandibles against any hard substance, as a signal to the other guards, or as an encouragement to the labourers; they then retire, and are succeeded by the labourers, each with its burden of tempered mortar in its mouth; these diligently set about to repair whatever injury has been sustained. One of these attend every six or eight hundred labourers which are building a wall, taking no active part itself, but frequently making the noise above mentioned, which is constantly answered by a loud hiss from all the labourers, which at this signal evidently redouble their diligence.

TERRIER, a book or roll, wherein the several lands, either of a private person, or of a town, college, church, &c. are described. It should contain the number of acres, and the site, boundaries, tenants' names, &c. of each piece or parcel.

TESSELLATED PAVEMENTS, those of rich mosaic work, made of curious square marbles, bricks, or tiles, called tessels from their resembling dice.

TEST ACT. A statute 25 Car. II. cap. 2, which requires all officers, both civil and military, to take the oaths and test, viz. the sacrament, according to the rights and ceremonies of the church of England. Various ineffectual attempts have been made by the Dissenters to obtain the repeal of this act, which is evidently offensive to the genuine principles of civil and religious liberty.

TESTACEA, in the Linnæan system of natural history, the third order of vermes. This order comprehends all shell-fish, arranged by Linnæus under thirty-six genera. Shell-fish are animals with a short body, covered by or enclosed in a firm, hard, and stony habitation, composed according to their three separate orders.

TESTAMENT, in Law, a solemn and authentic act, whereby a person declares his will, as to the disposal of his estate, effects, burial, &c.

TESTUDO, the Tortoise, in Natural History, a genus of amphibibia, of the order reptiles. These animals feed on sea-weeds or on worms, are extremely prolific; but in the state of eggs, and while very young, are the prey of various animals. Their movements are slow; they are capable of being tamed, and will in that state eat almost any thing presented to them. They exist long in such air as would be destructive to other animals of the same size, and have such tenaciousness of life, that it is stated that they will exhibit convulsive movements for several days after their bodies have been opened, and even after their heads have been cut off. In cold latitudes the land tortoise is torpid during the winter. There are thirty-five species, of which we shall notice the following.—The common tortoise. The weight

of this animal is three pounds, and the length of its shell about seven inches. It abounds in the countries surrounding the Mediterranean, and particularly in Greece, where the inhabitants not only eat its flesh and eggs, but frequently swallow its warm blood. In September or October it conceals itself, remaining torpid till February, when it re-appears. In June it lays its eggs in holes exposed to the full beams of the sun, by which they are matured. The males will frequently engage in severe conflicts, and strike their head against each other with great violence, and very loud sounds. Tortoises attain most extraordinary longevity, and one was ascertained to have lived in the gardens of Lambeth to the age of nearly one hundred and twenty years. Its shell is preserved in the archiepiscopal palace. So reluctant is the vital principle to quit these animals, that Shaw informs us from Redi, one of them lived for six months after all its brains were taken out, moving its limbs and walking as before. Another lived twenty-three days after its head was cut off, and the head itself opened and closed its jaws for a quarter of an hour after its separation from the body. It may not only be tamed, but has in several instances exhibited proof in that state of considerable sagacity, in distinguishing its benefactors, and of grateful attachment in return for their kindness, notwithstanding its general sluggishness and torpor. It will answer the purpose of a barometer, and uniformly indicates the fall of rain before night, when it takes its food with great rapidity, and walks with a sort of mincing and clate step. It appears to dislike rain with extreme aversion, and is discomfited and driven back only by a few and scarcely perceptible drops.—The mud tortoise, is common both in Europe and Asia, and particularly in France, where it is much used for food. It is seven inches long; lays its eggs on the ground, though an aquatic animal; walks quicker than the land tortoise; and is often kept in gardens, to clear them from snails and various wingless insects. In fish-ponds it is very destructive, biting the fishes, and, when they are exhausted by the loss of blood, dragging them to the bottom and devouring them.—The fierce tortoise, is found in several parts of North America, and is eighteen inches long. It is rapid and vigorous in its movements, and will spring on its enemy with great elasticity and violence. Its flesh is thought extremely good. It is found in the muddy parts of rivers, concealing itself among the weeds. It will also dart with great celerity on birds.—The sea tortoises, or turtles, are distinguished from the former, by having very large and long feet in the shape of fins, the claws of some of the toes not being visible but enclosed. The common green turtle is not unfrequently five feet long, and of the weight of 600 pounds; and is denominated green from the shade of that colour assumed by the fat, when the animal is in its perfect state. In the West Indies it has been long in the highest estimation for the table, and within sixty or seventy years it has gradually been advancing in reputation in this country, for food, and is at present considered as furnishing the highest gratification of epicurism. It is imported into England in vast numbers. It feeds on sea grass, called turtle grass. It is taken sometimes after being watched to its haunts; and being thrown on its back, is unable to rise again on its feet: sometimes it is struck in the water with a long staff armed with iron at the end. The markets of the West Indies are supplied with the flesh of these animals, as those of Europe are with mutton and beef; and before they were much sought as articles for exportation, forty sloops were employed by the inhabitants of Port Royal in catching them. They are seldom seen on land but at the season of laying their eggs, which they do at several times, after intervals of fourteen days. They are occasionally found, probably in consequence of tempests, on the coasts of Europe. The imbricated turtle, or hawks-bill, is so called from its shells lapping one over another, like tiles on the roof of a house. It is about three feet long; is found in the seas both of Asia and America, and sometimes also in the Mediterranean; and is said to have been seen even of 600 pounds weight. Its flesh is of no estimation; but its lamina are manufactured into the elegant material known by the name of tortoise-shell, which has been applied by human ingenuity to innumerable purposes both of use and ornament. The thickness of the plate varies in reference to the age and size of the turtle. Those of a very young one are of no value. A large one will supply ten pounds' weight of valuable scales, which

being softened by heat, and lapped over each other by means of pressure, become effectually united, so as to constitute one piece of considerable extent, and without any perceivable trace of their separation. This article was well known to the Greeks and Romans, and was an important material of luxury and commerce. Various articles of furniture, and even beds, were inlaid with it. The Egyptians exported large cargoes of it to Rome for these purposes, and in China, as well as Europe, it is at present in very high demand for elegant and ornamental manufactures.

TESTUDO, in the Military Art of the ancients, was a kind of cover or screen which the soldiers, *e. gr.* a whole company, made themselves of their bucklers, by holding them up over their heads, and standing close to each other. This expedient served to shelter them from darts, stones, &c. thrown upon them, especially those thrown from above, when they went to the assault.

TESTUDO, was also a kind of large wooden tower which moved on several wheels, and was covered with bullocks' hides, serving to shelter the soldiers when they approached the walls to mine them, or to batter them with rams.

TETANUS, in Surgery, a locked jaw.

TETRAEDRON, or **TETRAHEDRON**, in Geometry, is one of the five Platonic or regular bodies or solids, comprehended under four equilateral and equal triangles. Or, it is a triangular pyramid of four equal and equilateral faces.

TETRAGON, in Geometry, a quadrangle, or a figure with four angles.

TETRANDRIA, the fourth class in Linnæus's sexual system.

TETRAO, in Natural History, a genus of birds of the order gallinæ. Birds of this genus, which according to Gmelin comprehends the grouse, the partridge, and the quail, follow the dam immediately on being hatched, and before the shell is wholly detached from them; their bill is strong and convex, and their flesh and eggs form an exquisite repast. There are seventy-three species, of which the following are best deserving of notice.—The cock of the wood, is of the size of a turkey, and is found from Russia to Italy, preferring the elevated and mountainous parts of temperate countries, as it delights in a cold temperature. Its eggs are deposited on moss, and whenever left by the female, which is unassisted in the process of incubation, are covered over with leaves. The males and females live separate, except during the months of February and March. Their food consists of various plants and grains, and buds of trees. The seeds of the pine and fir they are particularly fond of.—The black grouse, is larger than a common fowl, and abounds in the British islands, particularly in the northern districts. The birds of this species, and of the last, do not pair like other birds, and the male is generally seen with several females in his train. They subsist on seeds and herbage, and are particularly fond of the seeds of the birch and Siberian poplar.—The ptarmigan grouse, is fourteen inches long, and inhabits the north of Europe. It is not uncommon in the Highlands and the Hebrides, and is sometimes found in Cumberland. These birds subsist on seeds, fruits, and berries, and are silly and inadvertent to danger.—The common partridge, is thirteen inches long, and abounds in the temperate regions of Europe; it is unable to sustain rigorous cold or intense heat.

See QUAIL.

TETRAPLA, a Bible disposed by Origen under four columns, in each of which was a different Greek version, namely, that of Symmachus, of Aquila, of the Seventy, and of Theodotian.

TEUTONIC ORDER, a military order of knights, established towards the close of the twelfth century, and thus called as consisting chiefly of Germans or Teutons. The origin, &c. of the Teutonic order is said to be this; the Christians under Guy of Lusignan, laying siege to Acre, a city of Syria, on the borders of the Holy Land, some Germans of Bremen and Lubeck, touched with compassion for the sick and wounded of the army, who wanted common necessities, set on foot a kind of hospital under a tent, which they made of a ship's sail, and here betook themselves to a charitable attendance on them. This excited a thought of establishing a third military order, in imitation of the Templars and Hospitaliers. The design was approved of by the patriarch of Jerusalem, the archbishop and bishops of the neighbouring places, the king of Jerusalem, the masters of

the temple and hospital, and the German lords and prelates then in the Holy Land, and Pope Calixtus III. confirmed it by his bull, and the new order was called the Order of Teutonic Knights of the House of St. Mary at Jerusalem. The pope granted them all the privileges of the Templars and Hospitallers of St. John, excepting that they were to be subject to the patriarchs and other prelates, and that they should pay tithes of what they possessed.

TEXT, a relative term, contradistinguished to gloss or commentary, and signifying an original discourse, exclusive of any note or interpretation. This word is particularly used for a certain passage of scripture chosen by a preacher to be the subject of a sermon.

THALLITE, a stone found in the fissures of mountains in Dauphiny, and on Chamouni in the Alps. It is sometimes amorphous, and sometimes crystallized.

THATCH, prepared straw or reed, laid on the top of ricks, stacks, or houses, to keep out the wet.

THEATRE, a public edifice for the exhibition of scenic spectacles and shows, to amuse the people, and also a place for dramatic representations. In Surgery, it is the room in which anatomical dissections are carried on.

THEFT, in Law, an unlawful felonious taking away another man's moveable and personal goods, against the owner's will, with intent to steal them. It is divided into theft or larceny, properly so called, and petit theft, or petit larceny; the former whereof is of goods above the value of 12d. and is deemed felony; the other, which is of goods under that value, is not felony.

THEFTBOTE, the receiving a man's goods again from a thief, or other amends by way of composition, and to prevent prosecution, that the felon may escape unpunished; the punishment whereof is fine and imprisonment.

THEME, a subject or topic on which to write or compose.

THEODOLITE, a mathematical instrument much used in surveying, for the taking of angles, distances, &c.

THEOGONY, the science which treats of the primitive, chaotic, or elementary state of things.

THEOLOGY, the science which instructs mankind in the knowledge of God and divine things; or that which has God, and what he has revealed, for its object.

THEOREM, a proposition which terminates in theory, and which considers the properties of things already made or done. Or, theorem is a speculative proposition deduced from several definitions compared together.

THEORY, a doctrine which terminates in speculation, without any view to the practice or application of it.

THERMOMETER, an instrument for ascertaining the temperature, that is, for measuring the degree of heat or cold, in any body. The thermometer was invented about the beginning of the 15th century; but, like many other useful inventions, it has been found impossible to ascertain to whom the honour of it belongs. Fahrenheit's thermometer consists of a slender cylindrical tube, and a small longitudinal bulb. To the side of the tube is annexed a scale, which Fahrenheit divided into 600 parts, beginning with that of the severe cold which he had observed in Iceland in 1709, or that produced by surrounding the bulb of the thermometer with a mixture of snow or beaten ice, and sal ammoniac or sea salt. This he apprehended to be the greatest degree of cold, and accordingly he marked it, as the beginning of his scale, with 0; the point at which mercury begins to boil, he conceived to shew the greatest degree of heat, and this he made the limit of his scale. The distance between these two points he divided into 600 equal parts or degrees; and by trials he found that the mercury stood at 32 of these divisions when water just begins to freeze, or snow or ice just begins to thaw; it was therefore called the degree of the freezing point. When the tube was immersed in boiling water, the mercury rose to 212, which therefore is the boiling point, and is just 180 degrees above the former, or freezing point. But the present method of making the scale of these thermometers, which is the sort in most common use, is first to immerge the bulb of the thermometer in ice or snow just beginning to thaw, and mark with 32 the place where the mercury stands; then immerge it in boiling water, and again mark the place where the mercury stands in the tube with the number 212, exceeding the former by 180; dividing therefore the intermediate space into

180 equal parts, will give the scale of the thermometer; which may afterwards be continued upwards and downwards at pleasure. Other thermometers of a similar construction have been accommodated to common use, having but a portion of the above scale. They have been made of a small size and portable form, and adapted with appendages to particular purposes; and the tube, with its annexed scale, has often been enclosed in another thicker glass tube, also hermetically sealed, to preserve the thermometer from injury. And all these are called *Fahrenheit's thermometers*.

The thermometer at present used in France is called *Reaumur's*; but it is very different from the one originally invented by Reaumur in 1730, and described in the Memoirs of the Academy of Sciences. The one invented by Reaumur was filled with spirit of wine; and though its scale was divided by the author into 80 parts, of which 0 was the freezing point, and 80 the boiling-water point, yet in fact 80 was only the boiling point of the spirit of wine that he employed, which, as Dr. Martine computes, corresponded with 180 of Fahrenheit. But the thermometer now in use in France is filled with mercury; and the boiling-water point, which is at 80, corresponds with the 212th degree of Fahrenheit. The scale indeed commences at the freezing point, as the old one did. The new thermometer ought more properly to be called *De Luc's thermometer*, for it was first made by De Luc; and is in fact as different from Reaumur's as it is from Sir Isaac Newton's. When De Luc had fixed the scale, and finished an account of it, he shewed the manuscript to M. De la Condamine. Condamine advised him to change the number 80; remarking, that such was the inattention of philosophers, that they would probably confound it with Reaumur's. De Luc's modesty, as well as a predilection for the number 80, founded as he thought on philosophical reasons, made him decline following this advice. But he found by experience that the prediction of Condamine was too well founded. The thermometer of Celsius, which is used in Sweden, has a scale of 100 degrees from the freezing to the boiling-water point. This is, in fact, the *centigrade thermometer*. These are the principal thermometers now used in Europe; and the temperature indicated by any of them may be reduced into the corresponding degrees on any of the others, by means of the following simple theorems; in which R signifies the degrees on the scale of Reaumur, F those of Fahrenheit, and S those of the Swedish thermometer.

1. To convert the degrees of Reaumur into those of Fahrenheit; $\frac{R \times 9}{4} + 32 = F$. 2. To convert the degrees of Fahrenheit to those of Reaumur; $\frac{(F - 32) \times 4}{9} = R$. 3. To convert the Swedish degrees into those of Fahrenheit; $\frac{S \times 9}{5} + 32 = F$. 4. To convert Fahrenheit's into Swedish; $\frac{(F - 32) \times 5}{9} = S$. 5. To convert Swedish degrees into those of Reaumur; $\frac{S \times 4}{5} = R$. 6. To convert Reaumur's degrees into Swedish; $\frac{R \times 5}{4} = S$.

To such readers as are unacquainted with the algebraic expression of arithmetical formulæ, it will be sufficient to express one or two of these in words, to explain their use;—1. Multiply the degree of Reaumur by 9, divide the product by 4, and to the quotient add 32; the sum expresses the degree on the scale of Fahrenheit. 2. From the degree of Fahrenheit subtract 32, multiply the remainder by 4, and divide the product by 9, the quotient is the degree according to the scale of Reaumur, &c.—As in meteorological observations it is necessary to attend to the greatest rise and fall of the thermometer, attempts have been made to construct a thermometer which might register the greatest degree of heat, or greatest degree of cold, which took place during the absence of the observer.—The following is properly a spirit thermometer, though mercury is employed in it for the purpose of supporting a certain index; as

(fig. 1, is) a tube of thin glass, about sixteen inches long, and $\frac{1}{4}$ of an inch in diameter; *c d e f g h* is a smaller tube, with the inner diameter about $\frac{1}{16}$ in, joined to a larger at the upper end *b*, and bent down first on the left side, and then, after descending two inches below *a b*, upwards again on the right, in the several directions *c d e f g h*, parallel to, and one inch distant from it. At the end of the same tube, at *h*, the inner diameter is enlarged to half an inch from *h* to *i*, which is two inches in length. This glass is filled with highly rectified spirit of wine to within half an inch of the end *i*, excepting that part of the small tube from *d* to *g* which is filled with mercury. From a view of the instrument, it will be readily conceived that when the spirit in the large tube is expanded by heat, the mercury in the small tube on the left side will be pressed down, and cause that on the right side to rise; on the contrary, when the spirit is condensed by cold, the reverse will happen. Fahrenheit's scale, which begins with 0 at the top of the left side, has the degrees numbered downwards, while that at the right side, beginning with 0 at the bottom, ascends. The divisions are ascertained by placing the thermometer with a good standard mercurial one in water, gradually heating or cooling, and marking the divisions of the new scale at every five degrees. The divisions below the freezing point are taken by means of a mixture of sea-salt and ice, as described by Nollet, De Luc, and others. In order to shew how high the mercury has risen in the observer's absence, there is placed within the small tube of the thermometer, above the surface of the mercury on either side, immersed in the spirit of wine, a small index, so fitted as to pass up and down as occasion may require. One of these indices is represented in fig. 2; *a* is a small glass tube, three-quarters of an inch long, hermetically sealed at each end, enclosing a piece of steel wire nearly of the same length; at each end, *e d*, is fixed a short piece of a tube of black glass, of such a diameter as to pass freely up and down within the small tube of the thermometer. The lower end floating on the surface of the mercury, is carried up with it when it rises, while the piece at the upper end, being of the same diameter, keeps the body of the index parallel to the sides of the thermometrical tube. From the upper end of the body of the index at *c* is drawn a spring of glass to the fineness of a hair, about four-fifths of an inch in length, which being set a little oblique, presses lightly against the surface of the tube, and prevents the index from following the mercury when it descends, or being moved by the spirit passing up and down, or by any sudden motion given to the instrument; but at the same time the pressure is so adjusted as to permit this index to be readily carried up by the surface of the rising mercury, and downwards whenever the instrument is rectified for observation. The index, by not returning with the mercury when it descends, shews distinctly and accurately how high the mercury has risen, and consequently what degree of cold or heat has happened. To prevent the spirit from evaporating, the tube at the end *i* is closely sealed. The daily rectification of this instrument is performed by applying a small magnet to that part of the tube against which the index rests; by the action of which the included piece of steel wire, and consequently the index, is easily brought down to the surface of the mercury. When this has been done, the instrument is rectified for the next day's observation, without heating, cooling, separating, or at all disturbing the mercury, or moving the instrument. With a thermometer of this sort, Mr. Six observed the greatest degree of heat and cold that happened every day and night throughout the year 1781.

In 1790 two thermometers were invented by Dr. John Ruthersford; the one for registering the highest, and the other for registering the lowest degree of heat to which the thermometer has risen or fallen during the absence of the observer. A new

self-registering thermometer has more recently been invented by Mr. Keith, of Ravelstone, which Dr. Gregory considers as the most ingenious, simple, and perfect, of any which has hitherto appeared. Its simplicity is so great, that it requires only a very short description to make it intelligible. It is constituted first of a thin glass tube about fourteen inches long, and $\frac{3}{4}$ of an inch caliber, close or hermetically sealed at top. To the lower end, which is open, there is joined a crooked glass tube seven inches long, and $\frac{4}{10}$ of an inch caliber, and open at its top, which, of course, is level with the middle of the first tube. The former tube is filled with the strongest spirit of wine, and the latter tube with mercury. This is properly a spirit-of-wine thermometer, and the mercury is used merely to support a piece of ivory or glass, for which is affixed a wire for raising one index or depressing another, according as the mercury rises or falls. There is a small conical piece of ivory or glass, of such a weight as to float on the surface of the mercury. To the float is joined a wire called the *float wire*, which reaches upwards, where it terminates in a knee bent at right angles. The float-wire, by means of an eye fixed at its extremity, moves easily along a small vertical harpsichord wire. There are two indexes made of thin black oiled silk, which slide upwards or downwards with a force not more than two grains. The one placed above the knee points out the greatest rise, and the one placed below it points out the greatest fall, of the thermometer.

When the instrument is to be prepared for an observation, both indexes are to be brought close to the knee. It is evident, that when the mercury rises, the float and float-wire, which can be moved with the smallest force, will be pushed upwards till the mercury becomes stationary. As the knee of the float-wire moves upwards, it will carry along with it the upper index. When the mercury again subsides, it leaves the index at the point to which it was raised, for it will not descend by its own weight; as the mercury falls, the float-wire does the same; it therefore brings along with it the lower index, and continues to depress it till it again becomes stationary, or ascends in the tube, in which case it leaves the lower index behind it, as it had formerly left the upper. The scale to which the indexes point is placed parallel to the slender harpsichord wire. That the scale and indexes may not be injured by the wind and rain, a cylindrical glass cover, close at top, and made so as exactly to fit, is placed over it. The ingenious inventor has another improvement, which if upon trial it be found to answer, will make this thermometer as perfect as can be desired, provided there do not arise some errors from the variable pressure of the atmosphere. He proposes to adapt clock-work to this thermometer, in such a way as to register with the utmost precision the degrees of heat and cold for every month, day, and minute, in the year. An account of this latter improvement may be seen in Nicholson's Journal, vol. iii. 4to. series, or Edin. Trans. vol. iv.

The common contrivance for a self-registering thermometer, now sold in most of the London shops, consists simply of two thermometers, one mercurial and the other of alcohol, having their stems horizontal, as in the annexed figure: the former has for its index a small bit of magnetical steel wire, and the latter a minute thread of glass, having its two ends formed into small knobs by fusion in the flame of a candle.

The magnetical bit of wire lies in the vacant space of the mercurial thermometer, and is pushed forward by the mercury whenever the temperature rises, and pushes that fluid against it; but when the temperature falls and the fluid retires, this index is left behind, and consequently shews the maximum. The other index, or bit of glass, lies in the tube of the spirit thermometer immersed in the alcohol, and when the spirit retires by depression of temperature, the index is carried along

with it is apparent contact with its interior surface; but on increase of temperature the spirit goes forward, and leaves the index, which therefore shows the minimum of temperature since it was set. As these indexes merely lie in the tubes, their resistance to motion is altogether inconsiderable. The steel index is brought to the mercury by applying a magnet on the outside of the tube, and the other is duly placed at the end of the column of alcohol by inclining the whole instrument. When the surface of the column of spirit is viewed by a magnifier, it is seen to have the form of a concave hemisphere, which shows that the liquid is attracted by the glass. The glass in that place is consequently attracted in the opposite direction by a force equal to that which is so employed in maintaining that concave figure; and if it were at liberty to move, it would be drawn back till the flat surface was restored. Let us suppose a small stick or piece of glass to be loose within the tube, and to protrude into the vacant space beyond the surface of the alcohol. The fluid will be attracted also by this glass, and form a concave between its surface and that of the bore of the tube. But the small interior piece being quite at liberty to move, will be drawn toward the spirit so long as the attractive force possesses any activity; that is, so long as any additional fluid hangs round the glass; or, in other words, until the end of the stick of glass is even with the surface. Whence it is seen that the small pieces of glass will be resisted, in any action that may tend to protrude it beyond the surface of the fluid; and if this resistance be greater than the force required to slide it along in the tube (as in fact it is,) the piece must be slid along as the alcohol contracts; so as always to keep the piece within the fluid. And this fact is accordingly observed to take place.

Professor Leslie, well known for his genius, has invented a differential thermometer, for the measurement of minute variations of temperature. It consists of two tubes, each terminating in a small bulb of the same dimensions, joined by the blow-pipe, and bent in the form of a U, a small portion of dark coloured liquor having previously been introduced into one of the balls. After many trials, the fluid best adapted to the purpose was found to be a solution of carmine in concentrated sulphuric acid. By managing the included air with the heat of the hand, this red liquor is made to stand at the required point of the opposite tube. This is the zero of a scale fastened to that tube, and divided into equal parts above and below that point. The instrument is then fixed on a stand. It is manifest, that when the liquor is at rest, or points at zero, the column is pressed in opposite directions by two portions of air equal in elasticity, and containing equal quantities of caloric. Whatever heat, then, may be applied to the whole instrument, provided both bulbs resolve it in the same degree, the liquor must remain at rest. But if the one ball receives the slightest excess of temperature, the air which it contains will be proportionally expanded, and will push the liquid against the air in the other bulb with a force varying as the difference between the temperatures of those two portions of air; thus the equilibrium will be destroyed, and the fluid will rise in the opposite tube. The degrees of the scale through which it passes will mark the successive augmentations in the temperature of the ball which is exposed to the greatest heat. So that this instrument is a balance of extreme delicacy for comparing the temperature of its two scales.

It is a small variation from this thermometer that constitutes Mr. Leslie's Photometer. When thermometers are devised to measure very great degrees of heat, they are usually called by another name. See PYROMETER. The thermometer and barometer together are very useful in determining the altitudes of mountains, &c. For this purpose they are fixed in such a frame as to be conveniently portable. See BAROMETER.

THICK STUFF, planks thicker than those commonly used, which are placed opposite to the several scarfs or joinings in the frame of timbers.

THIMBLE, a covering for the finger, made of any metal, to protect it from the needle, in use among tailors, milliners, and all who are accustomed to sew.

THIMBLE, in the language of ship-riggers, is a sort of iron ring, whose outer surface is hollowed throughout its whole circumference, in order to contain in the channel or cavity a rope which is spliced about it, and by which it may be hung in any

particular situation. Its use is to defend the eye of the rope which surrounds it, from being injured by another rope which passes through it, or by the back of a tackle which is hung upon it.

THINKING, in general, any act or operation of the mind, but its physical principles are concealed from the eye of human penetration.

THISTLE, Order of the, or of St. Andrew a military order of knighthood in Scotland.

THISTLE, in Agriculture, a well-known prickly weed, common in cornfields. Of this troublesome plant there are various kinds. They indicate strong land, but require the watchful eye of the farmer.

THOLES, i.e. bearers or fulcrs, are small pins driven perpendicularly into the gunwale of a boat, and serving to retain the oars in that space which is called the row-lock; sometimes there is only one pin to each oar, as in the boats navigated in the Mediterranean sea. In that case, the oar is retained upon the pin by means of a strap, or of a cleat, with a hole through it, nailed on the side of the oar.

THOR, in Mythology, an ancient deity, worshipped among the northern nations, from whom our Thursday derives its name.

THORACIC, or **THORACICI**, a term applied to an order of fishes in the Linnean system: the character of this order is, that they have bony gills, and ventral fins directly under the thorax.

THORINA. An earth discovered in 1816 by M. Berzelius, in small quantities, in the gadolinite of Kararvet. It resembles zirconia.

THORN, in Botany, a name given to all trees and shrubs of the larger kind, which are armed with spikes or prickles.

THOUGHT, a general name for all the ideas consequent on the operations of the mind, and even for the operations themselves.

THRASHING, or **THRUSHING**, in Agriculture, the art of beating the corn out of the ears. There are several ways of separating corn from the ears; the first by beating it with a flail, which is properly what is called thrashing. The other method, still practised in several countries, is to make mules or horses trample on it backwards and forwards; this is properly what the ancients called tritura and tritatio. The Hebrews used oxen therein, and sometimes yoked four together for this purpose. Another way among the ancients was with a kind of sledg made of boards joined together and loaded with stone or iron, upon which a man was mounted, and the whole drawn over the corn by horses; this instrument was called traba or tribula. It is a rule among husbandmen, that the season for thrashing is as soon as the corn has sweated in the heap or mow.

THRASHING MACHINES, were first constructed in Britain about the year 1732; and various improvements took place till the invention of Mr. Andrew Meikle in 1786, who obtained a patent which has since expired: fig. 1, represents the plan of elevation; fig. 2, the ground plan; and fig. 3, the essential parts of the machinery, so as to convey a tolerably accurate idea of his principle. A, fig. 1, and 2, is a large horizontal spur-wheel, which has 276 cogs, and moves the pinion B, having fourteen teeth. The latter imparts motion to a crown-wheel C, that is provided with eighty-four cogs, and moves a second pinion D, which is furnished with sixteen teeth. This pinion D, turns the drum H I K L, fig. 1, 2, and 3, being a hollow cylinder, three feet

and a half in diameter, and placed horizontally: on its outside are fixed, by means of screw bolts, four scutchers, or pieces of

wood, one side of which is faced with a thin iron plate: and which are disposed at an equal distance from each other, and at right angles to the axis of the drum. P, fig. 2, and 3, is an inclined board, on which the sheaves are spread, and whence they are introduced between two fluted cast-iron rollers, G, G, fig. 3, that are three and a half inches in diameter, and revolve about thirty-five times in one minute. These rollers being only three-fourths of an inch from the scutchers or leaves of the drum H I K L, fig. 1, and 2, serve to keep the sheaves steady while the scutchers *a, b, c, d*, fig. 2, and 3, move with considerable velocity, and thus separate the grain from the straw, while both are thrown on the concave rack M, fig. 2, which lies horizontally

with slender parallel ribs; so that the corn may pass through them into the subjacent hopper N, fig. 1, and 3. O, fig. 3, is a riddle or harp, through which the corn drops into a pair of fanners, P, fig. 1 and 3, and from these it is generally obtained in a state fit for the market. Q R T S, is a rake consisting of four leaves, or thin pieces of wood; at the extremity of each is placed a row of teeth, *e, f, g, h*, that are five inches long. This rake moves in the concave rack M, fig. 2, in a circular direction; while the teeth catch the straw that had been thrown by the scutchers *a, b, c, d*, into the rack, and remove it to the contiguous place V. W, fig. 1, represents the horse's course, which is 27 feet in diameter. X, fig. 1 and 2, is the figure for supporting the beams on which the axle of the spur-wheel is fixed. Y, Y, Y, fig. 1, and Y, Y, fig. 2, shew the spindles, the design of which is to move the two fluted rollers, the rake, and the fanners.

To the description now given we have only to add, that the drum has a covering of wood at a small distance above it, for the purpose of keeping the sheaves close to the scutchers. The number of persons requisite for attending the mill when working is six: one person drives the horses; a second hands the sheaves to a third, who unties them; while a fourth spreads them on the inclined boards, and presses them gently between the rollers; a fifth person is necessary to riddle the corn as it falls from the fanners, and a sixth to remove the straw. This machine can be moved equally well by water, wind, or horses. Mr. Meikle has made such improvements on the windmill as to render it much more manageable and convenient than formerly; and we are informed many such windmills are erected in different parts of the country. As to the comparative expense of these different machines, the erection of the horse-machine is least; but then the expense of employing horses must be taken into consideration. One of this kind may be erected for 70*l*. A water-mill will cost 10*l*. more, on account of the expense of the water-wheel. A windmill will cost from 200*l*. to 300*l*. sterling. In thrashing machines, however, cheapness should not be the only consideration. It often happens in machinery that things

apparently cheap are ultimately very dear. Thrashing of corn requires a strong power, to which neither weak men nor slight machines are competent. On this account strong and durable machines are to be recommended as cheapest in the end; performing more work, in a better manner, and not needing frequent repairs. Some other well-constructed thrashing-machines are described in Gray's Experienced Millwright, Bailey's Descriptions of Machines approved by the Society of Arts, in the Repository of Arts and Manufactures, the 2d vol. of Dr. Brewster's Ferguson, and the 11th vol. of the Pantologia. With respect to the quantity of corn which a machine will thrash in a given time, it is not easy to give any precise information; the most important we have yet met with is given by Mr. Fenwick who found from numerous experiments that a power capable of raising a weight of 1000 pounds with a uniform velocity of fifteen feet per minute, will thrash two bolls (eight bushels) of wheat in an hour; and that a power sufficient to raise the same weight with a velocity of twenty-two feet per minute, will thrash three bolls of the same grain in an hour. From these facts, this gentleman has computed the following table, which is applicable to machines that are driven either by water or horses.

Gallons of water per minute, six months discharged on an overshot wheel 10 feet in diameter.	Gallons of water per minute, six months discharged on an overshot wheel 15 feet in diameter.	Gallons of water per minute, six months discharged on an overshot wheel 20 feet in diameter.	Number of horses working 9 hours and a half.	Bolls of wheat thrashed in an hour.	Bolls thrashed in 9 hours and a half actual working, or in a day.
230	180	130	1	2	19
390	296	206	2	3	28½
528	390	272	3	5	47½
660	470	340	4	7	66½
790	565	400	5	9	85½
970	680	500	6	10	95
7	2	3	4	5	6

The first four columns of the preceding table contain different quantities of impelling power, and the last two exhibit the number of bolls of wheat in Winchester measure, which such powers are capable of thrashing in an hour, or in a day. Six horses, for example, are capable of thrashing ten bolls of wheat in an hour, or ninety-five in the space of nine hours and a half, or a working day; and 680 gallons of water discharged into the buckets of an overshot water-wheel of 15 feet diameter during a minute, will thrash the same quantity of grain.

THRAVE, or THRAVE OF CORN, twenty-four sheaves, or four shocks of six sheaves to the shock, though in some counties they only reckon twelve shocks to the thrave.

THREAD, a small line made up of a number of fine fibres of any vegetable or animal substance, such as flax, cotton, or silk; from which it takes its name of linen, cotton, or silk thread.

THREATENING LETTER. If any person shall send any letter threatening to accuse any person of a crime punishable with death, transportation, pillory, or other infamous punishment, with a view to extort money from him, he shall be punished at the discretion of the court with fine, imprisonment, pillory, whipping, or transportation.

TROAT, among Seamen, is a name given to that end of a gaff which is next the mast, and is opposed to peek, which implies the outer end: hence, *Throat Brails*, are those which are attached to the gaff close to the mast. *Throat Halliards*, ropes or tackles applied to hoist the inner part of the gaff, and its appendent portion of the sail.

THRUM, (To,) a phrase at sea, which signifies to insert in a sail or mat, &c. through small holes made by a bolt-rope needle, or a marine spike, a number of short pieces of rope yarn, or spun yarn.

THUMMERSTONE. This stone was first described by Mr. Schreber, who found it near Balme D'auris in Dauphine, and gave it the name of short viole. It was afterwards found near Thum in Saxony, in consequence of which Werner called it *Thummerstone*. It is sometimes amorphous, but more commonly crystallized.

THUNDER, the noise occasioned by the explosion of a flash of lightning passing through the air; or it is that noise which is excited by a sudden explosion of electrical clouds, which are therefore called thunder-clouds. The rattling in the noise of thunder, which makes it seem as if it passed through arches, is probably owing to the sound being excited among clouds hanging over one another, and the agitated air passing irregularly between them. The explosion, if high in the air, and remote from us, will do no mischief; but when near, it may and has, in a thousand instances, destroyed trees, animals, &c. This proximity, or small distance, may be estimated nearly by the interval of time between seeing the flash of lightning, and hearing the report of the thunder, estimating the distance after the rate of 1·142 feet per second of time, or $\frac{3}{8}$ seconds to the mile.

THWARDS, the seats or benches of a boat whereon the rowers sit to manage the oars.

THYMUS, **THYME**, a well-known aromatic garden plant, highly useful for domestic and medicinal purposes.

TIARA, an ornament with which the ancient Persians covered their heads.

TICK, a troublesome insect which infests cows, goats, sheep, dogs, horses, and occasionally man.

TIDE, a regular periodical current of the water, setting alternately in a flux and reflux, and is produced by the influence of the moon. Locke, in describing the theory of the tides, observes, "That motion of the water, called tides, is a rising and falling of the sea; the cause of this is the attraction of the moon, whereby the part of the water in the great ocean which is nearest the moon, being most strongly attracted, is raised higher than the rest; and these two opposite elevations of the surface of the water in the great ocean following the motion of the moon from east to west, and striking against the large coasts of the continents; from thence rebound back again, and so make floods and ebbs in narrows, seas, and rivers."

The great Sir Isaac Newton undertook to explain the doctrine of the tides upon the two great principles of gravity and attraction. However irregular they might be in certain instances, and with a view to certain objects, it was evident, that from the stated intervals of the time which they preserved, some common and general cause must exist to produce such a regular effect. Continued observation had ascertained one striking and remarkable fact on all the coasts of the British dominions in Europe, and along the coasts of Holland, France, Spain, and Portugal, that the hour of high water, considered generally, was regularly and uniformly at a certain interval or portion of time after the moon had passed the meridian of such place. The acute and sagacious mind of this philosopher was, from mature deliberation, and attention to this fact, soon convinced that the moon had an influence upon the great body of the waters of the ocean, and that the only remaining subject of consideration was, to discover how far this principle would agree with the different quantity of waters which were accumulated at those intervals on different days. On this subject he might thus judiciously argue with himself: If it be true that the moon has an influence on the waters of the ocean, so as to occasion their accumulation in a regular and periodical way, which cannot be done by any thing but the force of attraction, it is equally probable, that the other heavenly bodies should have some influence to the same purpose. But the sun alone, from his magnitude, is capable of doing this in any considerable or sensible degree, and though from his distance that effect and influence be very much lessened, yet, upon calculation, it would be found to bear a proportion extremely well suited to obviate the remaining difficulty. First, it should be observed, that the earth has a daily revolution on its axis every twenty-four hours from west to east, which occasions the sun and other heavenly bodies apparently to move from east to west. But the moon, from her actual motion in the heavens towards the east, of a little more than twelve degrees daily, or near forty-nine minutes of time at a medium, occasions her coming upon the meridian of any place later by forty minutes daily than on each next preceding day, so as to take up about twenty-nine days and a half on an average from one new moon to another. Now, if both the sun and moon are supposed to have an attractive power and influence on the waters in the ocean, it must follow,

that when they happen to be on the meridian at the same time, or nearly so, this attraction of each, whatever may be the proportion between them, must be the same way. It will from hence follow, that the effect of the sun's influence must in this case be added to that of the moon, and consequently an increased accumulation of waters must be produced. This is in reality the case at every new moon, when these two attractive bodies affect the waters of the ocean the same way, and cause higher tides, which are usually known by the name of spring tides. This will also account for the same sort of tides at the full moon, when the moon is at the greatest distance from the sun, or due north when the other is south. For we shall presently see, that the accumulated tides will always take place on the opposite parts of the world, to preserve a proper equilibrium, unless where other causes operate to the contrary; and therefore, though the two attracting bodies be in opposite parts of the heavens, they will operate jointly, as at the new moon, to produce high tides. On the contrary, when they are at the distance of a quarter of the heavens from each other, or ninety degrees, their influence will be manifestly different from each other, and the attraction will operate on different parts of the ocean, so as to counteract one another. Hence it would follow, that if the attractive power of these two bodies were equal, they would then destroy each other, as their united power at the full and new moons would be double to either of them singly. This, however, is not the case, though it is certain that at the time of the quarters of the moon, when the moon still evidently retains a prevailing influence, it is much counteracted by the attractive power of the sun, so that the tides are comparatively much less, and are known by the name of neap tides. It is likewise to be observed, that the tides, from the prevailing influence of the moon, would always naturally follow her from east to west, if the obstructions of land lying in the way did not prevent it. But water, as a ponderous body, though fluid, will more speedily seek to preserve its own level, and is less liable to interruption from slight causes, than the air or atmosphere, so that whatever impediments it meets with, it turns round the shortest points of land for this purpose, and seeks every creek and river in its course, that no part of the sea or ocean may be deprived of its share of the tides, and to recover its level.

It will be evident on the principles of attraction and gravitation, that as the hemisphere nearest to the moon will be immediately under the effect of her attraction, and consequently, the waters of that half be prevented from gravitating towards the other, the opposite hemisphere will have less than its share of attraction, and consequently the gravitation will be diminished, from whence the waters of the extreme part will be higher than in any other part of the hemisphere, so that the tides will then be highest at the same time. Hence, at the distance of ninety degrees, where this influence can be little if at all perceived, the waters will be at liberty to descend towards the centre by the natural power of gravitation, and will therefore in those places be lowest. It has also been concluded, that where the moon's meridian altitude is great, the tides will be increased when she is above the horizon; and, on the contrary, that when her meridian depression is great, the night tides will be most considerable. This holds true in a less degree of the sun, and especially at the new moon, if she has north declination in summer, and south declination in winter. Also, if the moon is in such a part of her orbit as to be at the nearest distance from the earth, it will considerably add to the influence of her attraction; and it has been known to cause uncommonly high tides when this happens at the time of new or full moon. Generally understood, it has been noted, that the morning tides are the highest in winter, and the evening tides in summer. It has been observed, that the intervention of land causes a great alteration in the tides. This will show why there are little or no tides in small inland seas, such as the Baltic and Mediterranean, where the attractive influence of the sun and moon must be nearly equal at both the extremities, and cannot therefore sensibly affect the waters. It is also certain, that the tides are very inconsiderable in high latitudes, because the sun and moon more immediately act towards the equator, and raise the water towards the middle of the torrid zone, which must consequently render the waters of the frigid zone compara-

scarcely admit of any doubt, but to others, less conversant with their general language and modes of speech, may be less intelligible. We have sometimes also expressed ourselves generally of the time of spring tides; by which, likewise, is constantly meant the precise day of new or full moon, though the tides for two or three days are frequently represented by that term; and indeed, it has been observed from experience, that the highest tides are not usually till the third or fourth tide, according as the day or night tides are highest from other causes, after the actual new or full moon, whereas, in speaking of the time of spring tides generally, it is always to be understood of the very day. The time of high water being accordingly ascertained by observation at each particular port, the next conclusion resulting from thence has been to represent the point of the compass, being first corrected for variation on the day on which the moon is at that time. Having, therefore, determined this, according to the proportion of 11 degrees and a quarter for each point of the compass, pilots and seamen in general have attended to the rule in laying down the time of high water on the intermediate days between the spring-tides. This is, in other words, to allow three quarters of an hour for each point of the compass; and on this foundation it is that in places where it is high water at noon on full and change days, as at Southampton or Ostend, the tide is said to flow north and south at 12 o'clock. Thus also if the moon on those days bears 1, 2, 3, or more points to the eastward or westward of the meridian of any place at the time of high water, the tide is said to flow on such a point. For example, if the moon bears S.E. at the time of high water at Poole in Dorsetshire, the tide will here be said to flow at S. E. and N. W. and if E. or W. at Plymouth in Devonshire, it will be said to flow east and west. But it is a very improper way to depend on the point of the compass alone for the time when the moon is to be at high water, unless it has been converted into time, and ascertained by the interval after passing the meridian. Thus, for instance, if it were understood that the moon is always to be east or west at the precise time of high water at Plymouth, conclusions the most gross, erroneous, and dangerous, would be the result; because when the moon has a high north declination, it may happen that she may not be due east till near eight o'clock in the morning at Plymouth, which will almost be two hours after high water, and it would on the same day be due west soon after four o'clock in the afternoon, which will be nearly two hours before high water. It is needless to enlarge on the danger of abiding by this mode of calculation, without converting it into time at the rate of three-quarters of an hour for every point of the compass. But the general and only safe rule is, to say, that it will be high water at six hours after the moon has passed the meridian. It is high water in some places on the shore, or by the ground, while the tide continues to flow in the fair way or offing, as it is called, by which term is understood, that part of the sea in the neighbourhood, or at no great distance from any coast, where the tide-way is not particularly interrupted by the adjacent shore or high land. For this state of the tides it is customary to say, that the water flows tide and half tide, or tide and quarter tide, and the like, thereby considering the usual run of the tide at six hours, and the half tide at three hours, &c. When, therefore, the current or stream of the fair way in the offing of any coast is said to run tide and quarter tide, for instance, it means that the stream runs an hour and a half longer in the offing than it does by the shore, and consequently that it does not begin to run so soon any particular way at a distance from the coast as it does close by the land, by that interval of time.

There is yet one circumstance more to be noted respecting the mode of calculating the time of high water on the intermediate days between the spring-tide days. We have already pointed out the extremely dangerous notion of reckoning the tides by the points of the compass for any particular ports, and especially those which are nearest to the east and west. There is likewise another irregularity of considerable importance, which is, applying too generally and successively the rule of adding 49 minutes daily to the time of high water on each preceding day. Experience has proved this common method of calculation to be frequently erroneous.

With regard to the relative force of the tide on a ship floating 'herein, see the article CURRENT.

TIDE-GATE, a place in which a tide runs with great velocity. **To TIDE**, to work in or out of a river or harbour, or channel, by favour of the tide, and anchoring whenever it becomes adverse.

TIDES Man, an officer appointed by the custom-house to reside on board of merchant ships while they have any customable goods on board.

TIDE Mills, as their name imports, are such as employ for their first mover the flowing and ebbing tide, either in the sea or a river, and particularly the Thames, the Humber, and the Severn, in which the tide rises to a great height, furnishing a very powerful mover to drive any kind of machinery, and would allow of tide mills being very advantageously constructed upon their banks. The erection of such mills is not to be recommended universally, as they are attended with a considerable original expense, besides that some of their parts will require frequent repairs; but in some places where coals are very dear they may, on the whole, be found less expensive than steam engines to perform the same work, and may on that account be preferred even to them.

TIDE Way, the channel in which the tide sets.

TIDE Waiters, or **TIDSMEN**, are inferior officers belonging to the custom-house, whose employment it is to watch or attend upon ships until the customs are paid.

TIER, a name given to the range of cannon mounted on one side of a ship's deck.

TIER of the Cable, is a range of the fakes or windings of the cable, which are made within one another in a horizontal position.

Cable TIER, the space in the midst of a cable when it is coiled, also the place in which it is coiled.

TIER, also implies a range of casks in the hold; hence we say, the *Ground TIER*, or that which is next above the keelson, the second tier and upper tier.

TIERCE, or **TERCE**, a measure of liquid things, as wine, oil, &c. containing the third part of a pipe, or forty-two gallons.

TIGER. See **FELIS**.

TIGER Shell, a beautiful species of voluta, of a dusky red colour, spotted all over with large irregular blotches of white.

TIGHT, the quality whereby a vessel resists the penetration of any fluid, whether compressing its surface, or contained within it. Hence a ship is said to be tight when the planks are so solid as to prevent the entrance of the water, and a cask is called tight when none of the liquid contained therein can issue through or between the staves; in both senses it is opposed to leaky, which article see.

TIGILLUM, a word used by chemists to express the tile with which they cover the mouth of their crucibles; and, by others, for the crucible itself.

TILE, in building, a sort of thin brick, used on the roofs of houses; or more properly a kind of clayey earth, kneaded and moulded of a just thickness, dried, and burnt in a kiln like a brick, and used in the covering and paving of different kind of military and other buildings.

TILIA, in Botany, the *Lime Tree*, of which there are a great variety of species.

TILLAGE, the cultivating of land, or the means of bringing it into a state of preparation for depositing the seeds, and the growth of different crops.

TILLER, the bar or lever employed to turn the rudder in steering. See the article **HELM**.

TILLER Rope, the rope which forms a communication between the fore end of the tiller and the wheel, and is usually made of untarred rope.

TILT, a small canopy or awning of canvass or other cloth, extended over the stern sheets of a boat, and supported by iron work, or broad laths of flexible wood, incurvated. The tilt is principally used to keep off rain, as an awning is intended to defend from the sun's heat.

TILT, the covering of a cart, waggon, or other carriage, supported by hoops, and easily removeable when occasions require.

TILT Boat, is a boat covered with tarpawling or sail-cloth, to shelter the passengers, and such goods as might otherwise be exposed to the action of sun or rain.

TILT Hammer, a large and heavy hammer, put in motion by a water wheel or steam-engine. Cogs being brought to bear on

the tail of the hammer, its depression causes the head to be elevated, which, when liberated, falls with considerable force by its own specific gravity. Tilt mills work on the same principle.

TILTING of Steel, is the process by which blistered steel is rendered ductile. This is done by placing it under the tilt hammer.

TIMBER, includes all kinds of felled and seasoned woods. Of all the different kinds known in Europe, oak is the best for building, and even when it lies exposed to air and water there is none equal to it. Fir timber is the next in degree of goodness for building, especially in this country, where they build upon leases. It differs from oak in this, that it requires not much seasoning, and therefore no great stock is required beforehand. Fir is used for flooring, wainscoting, and the ornamental parts of building within doors. Elm is the next in use, especially in England and France; it is very tough and pliable, and therefore easily worked; it does not readily split, and it bears driving of bolts and nails better than any other wood; for which reason it is chiefly used by wheel-wrights and coach-makers, for shafts, naves, &c. Beech is also used for many purposes; it is very tough and white when young, and of great strength, but liable to warp very much when exposed to the weather; and to be worm-eaten when used within doors; its greatest use is for planks, bedsteads, chairs, and other household goods. Ash is likewise a very useful wood, but very scarce in most parts of Europe; it serves in buildings, or for any other use, when screened from the weather; handspikes and ears are chiefly made of it. Wild chesnut timber is by some esteemed as good as oak, and seems to have been much used in old buildings; but whether these trees are more scarce at present than formerly, or have been found not to answer so well as was imagined, it is certain this timber is now but little used. Walnut-tree is excellent for the joiner's use, it being of a more curious brown colour than beech, and not so subject to the worms. The poplar, alder, and aspen trees, which are very little different from each other, are much used instead of fir, and look well.—The goodness of timber not only depends upon the soil and situation in which it stands, but likewise on the season wherein it is felled. In this, people disagree very much; some are for having it felled as soon as the fruit is ripe, others in the spring, and many in the autumn. But as the sap and moisture of timber is certainly the cause that it perishes much sooner than it otherwise would do, it seems evident that timber should be felled when there is the least sap in it, viz. from the time that the leaves begin to fall till the trees begin to bud. This work usually commences about the end of April in England, because the bark then rises most freely; for where a quantity of timber is to be felled, the statute requires it to be done then for the advantage of tanning. After timber has been felled and sawed, it must be seasoned; for which purpose some advise it to be laid up in a very dry airy place, yet out of the wind and sun, or at least free from the extremities of either: and that it may not decay, but dry evenly, they recommend it to be daubed over with cow-dung. It must not stand upright, but lie all along, one piece over another, only kept apart by short blocks interposed to prevent a certain mouldiness, which they are otherwise apt to contract in sweating on one another; from which arises frequently a kind of fungus, especially if there be any sappy parts remaining. Others advise the planks of timber to be laid for a few days in some pool or running stream, in order to extract the sap, and afterwards to dry them in the sun or air. By this means, it is said, they will be prevented from either chopping, casting, or cleaving, but against skinking there is no remedy. Some again are for burying them in the earth, others in a heat, and some for scorching and seasoning them in fire, especially piles, posts, &c. which are to stand in water or earth. The Venetians first found out the method of seasoning or charring by fire; which is done after this manner; they put the piece to be seasoned into a strong and violent flame, in this they continually turn it round by means of an engine, and take it out when it is every where covered with a black coal crust; the internal part of the wood is thereby so hardened, that neither earth nor water can damage it for a long time afterwards.

TIMBER Trees, in Law, are properly oak, ash, and elm. In some particular countries, by local custom, other trees being

commonly there made use of for building, are considered as timber. Of these, being part of the freehold, larceny cannot be committed; but if they be severed at one time, and carried away at another, then the stealing of them is larceny. And by several late statutes, the stealing of them in the first instance is made felony, or incurs a pecuniary forfeiture. For the better preservation of roots, shrubs, and plants, it is enacted by 6 George III. c. 48, that every person convicted of damaging, destroying, or carrying away any timber tree or trees, or trees likely to become timber, without consent of the owner, &c. shall forfeit for the first offence not exceeding 20l. with the charges attending; and on non-payment shall be committed for not more than twelve, nor less than six months; for the second offence a sum not exceeding 30l. and on non-payment shall be committed for not more than eighteen, and not less than twelve months; and for the third offence, is to be transported for seven years. All oak, beech, chesnut, walnut, ash, elm, cedar, fir, asp, lime, sycamore, and birch trees, shall be deemed and taken to be timber trees, within the true meaning and provision of this act. Persons convicted of plucking up, spoiling, or taking away any root, shrub, or plant, out of private cultivated ground, shall forfeit, for the first offence, any sum not exceeding 40s. with the charges; for the second offence, a sum not exceeding 5l. with the charges; and for the third offence are to be transported for seven years. A power is given to justices of the peace to put this act in execution.

TIMBERS, the ribs of a ship, or the incurvated pieces of wood branching outward from the keel in a vertical direction, so as to give strength, figure, and solidity to the whole fabric. One timber is composed of several pieces united into one frame, which is accordingly called a frame of timbers, by the artificers.

Square TIMBERS, are those whose planes are perpendicular to the keel.

Cant TIMBERS, are those which are placed obliquely on the keel, as at the extremities of a ship.

Knuckle TIMBERS, are the foremost cant timbers on a ship's bow; the hindmost on the quarter are termed fashion pieces.

TIMBER and Room, or **Room and Space**, is the distance between the moulding edges of two adjoining timbers, which always contain the breadth of two timbers, and sometimes two or three inches between them.

Filling TIMBERS, are those which are put up between the frames. It must be observed, that one mould serves for two timbers, the fore side of the one being supposed to unite with the after side of the other, and so make only one line, which is actually the case in all the frames, which in some ships are every third, and in others every fourth timber. The frames are first put up and fastened to the ribbands, and afterwards the filling timbers are put up.

TIMBER Heads. See the article **KEVEL HEADS**.

TIME, a measure or portion of infinite duration. It is generally ascertained by the motions of the heavenly bodies.

TIME, in Music, is an affection of sound, by which we denominate it long or short with regard to its continuance.

TIME Keepers, in a general sense, denotes instruments adapted for measuring time. See **CHRONOMETER**.

TIMEKEEPER, or **TIMEPIECE**, an instrument adapted for measuring time. See the article **LONGITUDE**.

The following remarks on time-keepers were communicated by Joseph Whidbey Esq. master attendant at Sheerness yard, master of the Discovery sloop, and afterwards of the Sanspareil, and who surveyed 3000 leagues of the N. W. shore of America.—“When a time-keeper is received on board a ship, the greatest care should be taken to have it immediately secured in some convenient place in the cabin, where it may be the least liable to be moved during the voyage: it should never be touched but at the time of winding up, which ought to be at noon, and then with the greatest care, particularly avoiding circular motion. The makers of these instruments will affirm, that it is unnecessary to be thus particular in the care of them, and will tell you they may be carried about in the pocket, and moved from place to place, without being the least affected by it. I can only say, that I have been in the habit of using time-keepers for some years, and, notwithstanding the sanguine expectations of the makers as to their perfection, in my experience I have found the above precautions necessary. I have frequently

of the ship, any day and several times a day, if necessary, in any part of the ocean when the sun is visible. Secondly, it has before been recommended to take altitudes about 9^h or half past 3^h in the morning, for finding the longitude. Having these, you will always be sure of the first of double altitudes, should there be any appearance of losing the meridional altitude by clouds or mists arising near noon. Thus, it may frequently happen that the navigator may have both longitude and latitude, when, without the use of a time-keeper, he might be disappointed of both. Thirdly, it very often happens, particularly in high latitudes, that in a cloudy day the sun will shew itself on or about passing the meridian. Having a time-piece, you can tell, within a minute, when the sun is on the meridian: if an altitude can be caught about that time, even so far as ten minutes before or after the sun passes the meridian, that altitude will give the latitude nearly; for in such latitude, particularly when the sun's declination and the latitude are of different names, the sun's altitude alters very little in ten minutes on either side of noon. Fourthly, time-keepers are of great use in carrying on lunar distances from one day to another, so that a number of observations may be brought to one point. Altitudes being taken at the proper time by the time-piece, the apparent time thus obtained will answer for any lunar distances taken in the course of the succeeding twenty-four hours. The method of carrying on or deducing the time of taking the distances, to the time of taking altitudes for the longitude, may be illustrated as follows:

Suppose that altitudes are taken for the longitude in the morning, and that several sets of lunar distances are observed in the afternoon. Take the elapsed time from observing the altitudes, to the time of each set of distances, and when the Greenwich time of the distances is brought out, subtract this elapsed time from the Greenwich time of each set: each remainder will be the Greenwich time when the altitudes were taken, and will produce an observed longitude for that time; not for the time when the distances were observed. On the contrary, if lunar distances are observed before altitudes are taken for the apparent time, the elapsed time of each set must be added to the Greenwich time, to bring each set up to the time when the altitudes were taken. Observations of lunar distances also may be carried on from one time to another, so as to enable the observer, after having gained a number of sets on each side of the moon, to bring them all to one point by the time-piece, and get a mean of all the observations, which will give the true longitude, if the observations are good.—This may be explained as follows:

Suppose, on January 20th, I observe six sets of lunar distances; on the 21st, four more; on the 23d, six sets more:—the 23d being the last day, when the distances are in the Nautical Almanack on that side the moon, I bring each set of distances to the time when the altitudes were taken on their respective days: I then take the difference of longitude shewn by the time-piece, on the 20th and 23d, at the time altitudes were taken on each day: I apply that difference to each set taken on the 20th. I do the same between the 21st and 23d; each set will then be brought to the time when altitudes are taken on the 23d; in all sixteen sets. The mean of these, if the observations are good, cannot be far from the truth, and the result may be brought to noon on that day by the log. But to be more certain of the observed longitude, I will carry on the sixteen sets as above directed, till I have obtained sixteen sets on the other side of the moon. These thirty-two sets being all carried on to the last day of observing their mean, I may consider as nearly the true longitude. By this method you may judge whether time-pieces have altered their rates or not; and may even give them a new rate, in the same way that you would have done in harbour, as I have before explained. Thus the lunar distances and time-piece may be made to go hand in hand with each other, to discover the ship's true longitude. A time-piece must be a very bad one indeed, if it will alter its rate to such a degree as to affect the observations while carrying on as I have described. A small difference of rate they are all liable to, but this will not materially affect the observations. There is a small correction to be made at the time of the year when the daily difference of the equation is great. If the elapsed time between the altitudes, for the apparent time and the lunar distances be many hours, it will make an error of

some miles of longitude. This error, arising from the difference between mean and solar time, is not of much consequence at sea, or any where but in the observatory, where an astronomer is finding the exact longitude of his place by lunar distances, eclipses of Jupiter's satellites, occultations, transits, &c. When there are more time-pieces on board a ship than one, the same apparent time may be made to answer, to find the longitude by them all; by comparing the one, by which the altitudes were taken, with all the rest. Take the elapsed time between observing the altitudes and comparing; if the comparison is made after the observation, subtract this elapsed time from the time shewn by the second time-piece, when the comparison is made; the remainder is the time when the altitudes were taken, by the second time-piece: proceed then, as in common, to apply the error of its rate. The difference, then, between its time and the mean time at the ship, will be the longitude in time. For example: suppose altitudes were taken by No. 1, at 10^h 50' 51"; No. 2 was compared with it at 13^h 20' (by No. 1,) and shewed at that time 12^h 44' 36". The elapsed time between observing altitudes and comparing, is 2^h 38' 9"; which taken from 12^h 44' 36" leaves 10^h 6' 27", which is the time by No. 2, when the altitudes were taken. Suppose No. 2 to be slow of mean time at Greenwich 38' 40"; that, added to 10^h 6' 27" gives 10^h 45' 7", which is the mean time at Greenwich according to No. 2. Suppose the mean time at the ship to be 9^h 30' 56", the difference between these mean times is 1^h 14' 11", which turned into longitude, is 18° 32' 46"; and as the mean time at Greenwich is greater than at the ship, the longitude is west. You may proceed in the same way with any other time-pieces on board.—In addition to the observations already made on time-pieces, I must advert to the very great importance of these instruments to officers charged with fleets or convoys, with respect to making short passages from one part of the world to another. A person who has a good time-piece will be enabled to steer straight courses. This will shorten the distance much, and by that very circumstance will frequently enable him to get a fleet into port, before a shift of wind which might otherwise keep him out a long time. It will likewise give an officer a good chance of escaping the vigilance of a superior enemy; as he need not, according to the common system of navigation, run into the latitude of his port, in which his enemy may be cruising a few degrees of longitude to windward for him. He may run his longitude down thirty or forty leagues north or south of the port, as it may happen, till he is nearly or exactly in the longitude of it; and then steer north or south to his destination, as the case requires. This mode of navigation might prevent the capture of many a valuable ship, and would certainly, by shortening the passages, in many instances cause a great saving, not only to government, but to the merchant.

TIMONEER, the helmsman or person who manages the helm to direct the ship's course.

TIN. This metal has a fine white colour like silver, a slight disagreeable taste, and emits a peculiar smell when rubbed. Its specific gravity is 7.291. It is very malleable. Tin leaf or foil is about $\frac{1}{100}$ part of an inch thick, and it might be reduced to half this thickness. It is very flexible, and produces a remarkable crackling noise when bended, and when heated 442 deg. it melts. When exposed to the air, it very soon loses its lustre, and assumes a grayish white colour, but undergoes no farther change, neither is it sensibly altered by being kept under cold water; but when the stream of water is made to pass over red-hot tin, it is decomposed, the tin is oxidated, and hydrogen gas is evolved.

TIN-STONE, an ore of tin which occurs in masses, in rounded pieces, and crystallized. These crystals are very irregular. Colour dark-brown; sometimes yellowish gray; and sometimes nearly white. Somewhat transparent when crystallized. Specific gravity 6.9 to 6.97. Before the blow-pipe it decrepitates, and on charcoal is partly reduced. Tinges borax white.

TINCTURE, is commonly understood to be a coloured infusion of any substance in alcohol. It is a preparation much employed in pharmacy with many articles of the materia medica, particularly vegetable barks, aromatics of all kinds, and many of the resins and gum resins, which yield to alcohol, by infusion, that part of their substance in which most of the medicinal virtues reside.

TINNING. Tinning is the art of covering any metal with a thin coating of tin. Copper and iron are the metals most commonly tinned. What are commonly called tin-plates or sheets, so much used for utensils of various kinds, are in fact iron plates coated with tin.

The principal circumstance in the art of tinning is, to have the surfaces of the metal to be tinned perfectly clean and free from rust, and also that the tin may be perfectly metallic; and not covered with any ashes or calx of tin.

Tinning of Iron. When iron plates are to be tinned, they are first scoured, and then put into what is called a pickle, which is sulphuric acid diluted with water; this dissolves the rust or oxide that was left after scouring, and renders the surface perfectly clean. They are then again washed and scoured. They are now dipped into a vessel full of melted tin, the surface of which is covered with fat or oil, to defend it from the action of the air. By this means, the iron, coming into contact with the melted tin in a perfectly metallic state, it comes out completely coated. When a small quantity of iron only is to be tinned, it is heated, and the tin rubbed on with a piece of cloth or some tow, having first sprinkled the iron with some powdered resin, the use of which is to reduce the tin that may be oxidated. Any inflammable substance, as oil for instance, will have in some degree the same effect, which is owing to their attraction for oxygen.

Tinning of Copper.—Sheets of copper may be tinned in the same manner as iron. Copper boilers, saucepans, and other kitchen utensils, are tinned after they are made. They are first scoured, then made hot, and the tin rubbed on as before with resin. Nothing ought to be used for this purpose but pure grain tin; but lead is frequently mixed with the tin, both to adulterate its quality, and make it lie on more easily, but it is a very pernicious practice, and ought to be severely reprobated.

TITANIUM, a metal found in black sand, resembling gunpowder, in Cornwall. Its colour is orange red; and it has a good deal of lustre. As it has been only obtained in very small agglutinated grains, neither its hardness, specific gravity, nor malleability, has been ascertained. It is one of the most infusible of metals, requiring a greater heat to melt it than can be produced by any method at present known.

TITHES, are the tenth part of the increase yearly arising and accruing from the profits of lands, the stock upon lands, and the personal industry of the inhabitants. And hence they are usually divided into three kinds, prædial, mixed, and personal. Prædial tithes are such as arise merely and immediately from the ground, as grain of all sorts, hay, wood, fruits herbs; for a piece of land or ground being called in Latin prædium, whether it is arable, meadow, or pasture, the fruit or produce thereof is prædial, and consequently the tithe payable for such annual produce is called a prædial tithe. Mixed tithes are those which arise not immediately from the ground, but from things immediately nourished from the ground, as by means of cattle depastured thereupon, or otherwise nourished with the fruits; as colts, calves, lambs, chickens, milk, cheese, eggs. Personal tithes are such as arise from the labour and industry of man, employing himself in some personal work, artifice, or negotiation; being the tenth part of the clear gain, after charges deducted. Watts, c. 59. But this is seldom paid in England, except by especial custom.

TITLE, in Law, denotes any right which a person has to the possession of a thing; or an authentic instrument, whereby he can prove his right.

TOAD. See RANA.

TOBACCO. See NICOTIANA.

TODDY, a juice drawn from various kinds of palms, by cutting off such branches as nature intended to bear fruit, and receiving from the wound the sap designed for the nourishment of the future crop. This juice undergoes fermentation, and, with other ingredients, is used in the distillation of arrack.

TOGA, a wide woollen gown or mantle, without sleeves, used among the Romans both by men and women.

TOGETHER, in a nautical sense, the order given to the men, in the exercises of heaving, rowing, hauling, hoisting, &c. to act all in concert, or at the same time.

TOGGEEL, a small pin of wood, from four to six inches in length, and usually tapering from the middle towards the ex-

trimities, it is sometimes used instead of a hook in fixing a tackle, &c. In ships of war it is usual to fix toggeels upon the running parts of the topsail sheets, the gears, &c. when preparing for action, in such manner that if the rope is shot away below, the toggeel may stop the yard from coming down. This operation is called putting the sheets in the bockets. See the article BECKETS.

TOKAY WINE, derives its name from a town or village in Hungary, where this delicious and costly liquor is produced.

TOLERATION, in Religion, is the liberty granted under the protection of law, to those who dissent from the rites and constitution of an ecclesiastical establishment, permitting them to worship God without molestation, agreeably to the dictates of their consciences. Few subjects have generated more controversies than those to which toleration has given birth.

TOLUIFERA, the balsam or tolu tree, a genus of plants of the class decandria and order monogynia. There is only one species, the balsamum. This balsam possesses the same general virtues with the balsam of Gilead, and that of Peru. It is, however, less heating and stimulating, and may therefore be employed with more safety. It has been chiefly used as a pectoral, and is said to be an efficacious corroborant in glands and seminal weaknesses. It is directed by the pharmacopœias in the syrupus tolutaus, tinctura tolutana, and syrupus balsamicus.

TOMBAC, a metal composed of copper and arsenic.

TON WEIGHT, 20 hundred.

TONNAGE, a custom or impost due for merchandise brought or carried in tons from or to other nations, after a certain rate in every ton.

TONNAGE, the same with BURTHEN, which article see.

TONSURE, in Ecclesiastical History, a particular manner of shaving or clipping the hair of ecclesiastics or monks.

TONTINE, a variable kind of life annuity, but generally so contrived as to be progressively increasing in amount. It is formed by nominating a certain number of lives within limited ages, who for each one hundred pounds or any other gross sum paid down, are to receive at first a specific annuity; but as any of the lives fail, their annuity is to be equally divided among those that remain, by which means those individuals who happen to survive a considerable number of years, obtain a large augmentation of their annual receipt; and the longest liver of the whole (if there is no restriction to the contrary) gets, for the remainder of his life, the total sum which was paid at first to all the nominees. Tontines of this kind, if properly conducted, are considered by some persons as affording an eligible opportunity of making some provision for children, as the nomination of good healthy lives gives a good chance for survivorship. It has several times been attempted to raise money on this species of annuity for the service of government, but it has never been found practicable to obtain any considerable sum in this way; on a smaller scale it has been adopted successfully, both in Great Britain and Ireland, for procuring the sums necessary for building bridges, large inns or hotels, and other expensive edifices.

TOP, a sort of platform surrounding the lower-mast head, from which it projects on all sides like a scaffold. The principal intention of the top is to extend the top-mast shrouds so as to form a greater angle with the mast, and thereby give additional support to the latter. It is sustained by certain timbers fixed upon the bounds and cheeks of the masts, and called the trestle-trees and cross-trees. The top is also very convenient to contain the materials necessary for extending the small sails, and for fixing and repairing the rigging and machinery with greater expedition. In ships of war, the tops are furnished with swivels, musketry, and other fire-arms, and are guarded with a fence of hammocks in time of action. Here the top is used as a kind of redoubt, and is accordingly fortified for attack or defence, being furnished with swivels, musketry, and other fire-arms, and guarded by a thick fence of corded hammocks. Finally, the top is employed as a place for looking out either in the day or night.

Top-Armour, a rail about three feet high, extending the width of the top on the after-side, supported by stanchions, and equipped with a netting, and sometimes with painted canvases.

Top-Block. See the article BLOCK.

Top-Chain. See the article CHAIN.

Top-Cloth, a large piece of canvass, used to cover the hammocks, which are lashed in the top when prepared for action.

Top-Lantern, a large lantern placed in the after-part of a top in any ship where an admiral's flag or commodore's pendant is flying.

Top-Mast, the second division of a mast, or that part next above the lower-mast. See the article MAST.

Top-Gallant-Mast, the mast next above the top-mast, and is generally the uppermost mast.

Top-Rope, a rope employed to sway up a top-mast or top-gallant-mast, in order to fix it in its place, or to lower it in tempestuous weather, or when it is no longer necessary. The top-rope passes through a block which is hooked on one side of the cap, and afterwards through a hole furnished with a sheave on the lower end of the top-mast; it is then brought upwards on the other side of the mast, where it is fastened to an eye-bolt in the cap. To the lower end of the top-mast top-rope is fixed a tackle. See the article TOP-TACKLE. *Top-Rope*, is also the name of a rope used in swaying up or lowering down the top-gallant-yards.

Top-Sails, large sails extending across the top-masts by the top-sail yards above, and by the lower-yards beneath, being fastened to the former by earings and robands, and to the latter by means of the top-sail sheets, which passing through two great blocks fixed on its extremities, and from thence to two other blocks fixed on the inner part of the yard close by the mast, lead downwards to the deck.

Top-gallant-Sails, are extended above the top-sail-yards, in the same manner as the top-sails are extended above the lower-yards. See the article SAIL.

Top-Tackle, a large tackle hooked to the lower end of the top-mast top-rope, and to the deck, in order to increase the mechanical power in hoisting the top-mast. It is composed of two strong iron-bound double or triple blocks, the hooks of which work on a swivel.

Laying Top, a cylindrical piece of wood, having three or four scores or notches on its surface, used in rope-making, and varying in its size according to the thickness of the rope for which it is intended.

TOPAZ. The name topaz has been restricted by Mr. Haüy to the stones called by mineralogists occidental ruby, topaz, and sapphire; which, agreeing in their crystallization, and most of their properties, were arranged under one species by Mr. Rome de Lisle. The topaz is found in Saxony, Bohemia, Siberia, and Brazil, mixed with other minerals in granite rocks. The Siberian and Brazil topaz, when heated, become positively electrified on one side and negatively on the other. It is infusible by the blow-pipe. The yellow topaz of Brazil becomes red when exposed to a strong heat in a crucible; that of Saxony becomes white by the same process. This shows us that the colouring matter of these two stones is different.

TOPOGRAPHY, a description or draught of some particular place or small tract of land, as that of a city or town, manor or tenement, field, garden, house, castle, &c. such as surveyors set out in their plots, or make draughts of, for the information and satisfaction of the proprietors.

TOPPING, the act of pulling one of the extremities of a yard higher than the other, by slackening one of the lifts and pulling up the opposite one, so as to place the yard at a greater or lesser distance obliquely with the mast.

TOPPING Lift, a large and strong tackle employed to suspend or top the outer end of a gaff, or of the boom of a cutter, brig, sloop, or schooner's main-sail.

Top Men, persons stationed in the several tops to attend the taking in or setting of the upper sails.

TORMENTOR, an instrument much used in tillage, sometimes for breaking down the stiff clod, and at other times for skimming off the surface turf, that it may be prepared for being burnt. It bears in general appearance some resemblance to a harrow, only it is supported on wheels, and each tine is furnished with a hoe or share that enters and cuts up the ground.

TORNADO, a sudden and vehement gust of wind from all points of the compass, frequent on the coast of Guinea. A tornado seems to partake much of the nature of a whirlwind, or perhaps of a water spout, but is more violent in its effects. It

commences very suddenly, several clouds being previously drawn together, when a spout of wind proceeding from them strikes the ground in a round spot of a few rods or perches diameter, and proceeds thus half a mile or a mile. The proneness of its descent makes it rebound from the earth, throwing such things as are moveable before it, but some sideways or in a lateral direction from it. A vapour, mist, or rain, descends with it, by which the path of it is marked with wet. The following is a description of one which happened a few years since at Leicester, about 50 miles from Boston in New England; it happened in July, on a hot day, about four o'clock in the afternoon. A few clouds having gathered westward and coming overhead, a sudden motion of their running together in a point being observed, immediately a spout of wind struck the ground at the west end of a house, and instantly carried it away with a negro man in it, who was afterwards found dead in the path of it. Two men, and a woman, by the breach of the floor, fell into the cellar; and one man was driven forcibly up into the chimney-corner. These were preserved, though much bruised; they were wet with a vapour or mist, as were the remains of the floor, and the whole path of the spout. This wind raised boards, timbers, &c. A joist was found on one end, driven nearly three feet into the ground. The spout probably took it in its elevated state, and drove it forcibly down. The tornado moved with the celerity of a middling wind, and constantly declined in strength till it entirely ceased.

TORRID ZONE, among geographers, denotes that tract of the earth lying upon the equator, and on each side as far the two tropics, or 23° 28' of north and south latitude. The torrid zone was believed by the ancients to be uninhabitable, but is now well known to be even tolerable to the people of the colder climates, towards the north and south; the excessive heat of the day being there tempered by the coldness of the night.

TORTOISE SHELL, the shell of the testaceous animal called a tortoise; used in inlaying, and in various other works, as for snuff-boxes, combs, &c.

Toss (To) the Oars up, is to put them in a perpendicular direction, ready to let them all fall at once into the water, and is intended as a compliment to the passengers in the boat.

TOUCAN, in Astronomy, a constellation of the southern hemisphere, consisting of eight small stars, and otherwise called Anser Americanus.

TOUCH, or FEELING, Sense of. The sense of feeling differs from the other senses in belonging to every part of the body, external or internal, to which nerves are distributed. The term *touch* is most correctly applied to the sensibility which is diffused over the surface of the body. Touch exists with the most exquisite degree of sensibility at the extremity of the fingers and thumbs, and in the lips. The sense of touch is thus very commodiously disposed, for the purpose of encompassing smaller bodies, and for adapting itself to the inequalities of larger ones. The sensations acquired by the sense of feeling are those of heat, hardness, solidity, roughness, dryness, motion, distance, figures, &c. and all those corporeal figures which arise from a healthy or diseased state of the nerves, and the part of the body to which they belong. The pains of this sense are more numerous and vivid than those derived from any other sense; and therefore the relicts of them coalescing with one another, constitute the greatest share of our mental pains, that is, pains not immediately derived from sensation. On the other hand, its pleasures being faint and rare in comparison with others, and particularly those of the taste, have but a small share in the formation of the mental pleasures.

Touch-Needle, among assayers, refiners, &c. little bars of gold, silver, and copper, combined together in all the different proportions and degrees of mixture; the use of which is to discover the degree of purity of any piece of gold or silver, by comparing the mark it leaves on the touchstone with those of the bars.

TOUCH and Go, is spoken of a ship when under sail she rubs against the ground with her keel without much diminution of her velocity.

TOUCHING, is the state of a ship's sails when they first begin to shiver with their edges in the direction of the wind. It is either occasioned by an alteration in the ship's course, or by a change of the wind. See the article FULL and Br.

TOUCHING *At*, implies the circumstance of stopping or anchoring occasionally at some intermediate port in the course of the voyage.

TOURMALINE, in Mineralogy, a species of siliceous earth. The thickest parts are opaque; the thin, more or less transparent.

TOURNIQUET, a machine or instrument employed in the practice of surgery to stop bleeding. It can, however, only be applied to the limbs, and its use is only intended to be temporary.

Tow, (*To*) to draw a ship or boat forward in the water, by means of a rope attached to another vessel or boat, which advances by the effort of rowing or sailing. Towing is either practised when a ship is disabled, and rendered incapable of carrying sail at sea; or when her sails are not fixed upon the masts, as in a harbour; or when they are deprived of their force of action by a cessation of the wind. When a ship of war is dismasted, or otherwise disabled from carrying sail at sea, she is usually towed by a cable reaching from her bow to another ship ahead. In a harbour, towing is practised by one or more boats, wherein all the force of the oars is exerted to make her advance.

To take a vessel in Tow, is sometimes a figurative expression for taking care of her.

TOWING over Board, implies the act of drawing any thing after a ship or boat when she is sailing or rowing, which has previously been on board that ship or boat.

Tow-Line, a small hawser generally used to remove a ship from one part of a harbour or road to another by means of anchors, capstans, &c. See the article **WARPING**. It is also employed occasionally to moor a small vessel in a harbour conveniently sheltered from the wind and sea.

Tow Rope, a name given to any cable or other rope used in the exercise of towing.

TOWER, any high building raised above another, consisting of several stories, usually of a round form, though sometimes square or polygonal; a fortress, a citadel. Towers are built for fortresses, prisons, &c. as the tower of the Bastille, which was destroyed by the inhabitants of Paris in 1789.

TOXICODENDRON, the poisonwood.

TRACHEOTOMY, in Surgery, is the operation of making an opening into the windpipe.

TRACK of a Ship. See the article **WAKE**.

TRACKING, the act of pulling any vessel or floating body along the stream of a canal or river, by means of a rope extending from the vessel, &c. to an adjacent shore, and drawn along the banks of a river by men or horses. Whence

TRACK Schuyt, a vessel employed to carry goods and passengers up and down the rivers and canals in Holland, and the countries bordering on the Baltic sea.

TRADE, the practice of exchanging goods, wares, money, bills, and other articles of value, with the view of advantage or profit. It is generally distinguished into foreign trade, or the export and import of commodities to and from other countries, and the internal or home trade, or that which is carried on within the country; which two branches, however, are rather distinct in appearance than reality; for a very considerable portion of the internal trade arising from manufactures carried on to supply foreign markets, could not subsist without foreign commerce; while a large part of the returns for manufactures sent abroad, being articles for consumption or raw materials, which are converted to use in the different manufactures, depends upon our internal trade; so that the one supports the other, and by their mutual connexion and dependence, the foreign and the domestic trade of Great Britain have risen together to their present unparalleled height.

TRADE, implies the constant destination of any particular merchant vessel, as the Lisbon trade, West India trade, &c.

TRADE Winds, certain regular winds blowing within or near the tropics, and being either periodical or perpetual. Thus, in the Indian ocean they blow alternately from two opposite points of the compass, and in the Atlantic ocean continue almost without intermission in one direction; see the article **WIND**.

TRAGACANTH, GUM, or, as some call it, *gum adragant*, or *gum dragon*, is the produce of the above and some other shrubs. The gum is brought to us in long and slender pieces, of a flattened

figure more or less, and these not straight, or rarely so, but commonly twisted and contorted various ways, so as to resemble worms. We sometimes meet with it, like the other vegetable exudations, in roundish drops, but these are much more rare. It is moderately heavy, of a firm consistence, and, properly speaking, very tough rather than hard; and is extremely difficult to powder, unless first carefully dried, and the mortar and pestle kept dry. Its natural colour is a pale white, and in the clearest pieces it is something transparent. It is often, however, met with of a brownish tinge, and of other colours still more opaque. It has no smell and very little taste, but what it has is disagreeable. Taken into the mouth, it does not grow clammy and stick to the teeth, as the gum arabic does, but melts into a kind of very soft mucilage. It dissolves in water but slowly, and communicates its mucilaginous quality to a great quantity of that fluid. It is by no means soluble in oily or spirituous liquors, nor is it inflammable. It is brought to us from the island of Crete, and from several parts of Asia. It is to be chosen in long twisted pieces, of a whitish colour, very clear, and free from all other colours; the brown, and particularly the black, are wholly to be rejected.

TRAGEDY. See **POETRY**.

TRAIN, the hinder part of a gun carriage; also a line of gunpowder or other combustible materials, forming a communication with any body intended to be set on fire or exploded.

TRAIN Tackle, a combination of pulleys which during action is locked to an eye-bolt in the train of the carriage, and to a ring-bolt in the deck. Its use is to prevent the gun from running out of the port whilst loading.

TRAJECTORY, a term often used, generally for the path of any body moving, either in a void, or in a medium that resists its motion, or even for any curve passing through a given number of points.

TRAMMELS, in Mechanics, an instrument used by artificers for drawing ovals upon boards, &c. One part of it consists of a cross with two grooves at right angles; the other is a beam carrying two pins, which slide in those grooves, and also the describing pencil.

TRAMMEL NET, is a long net wherewith to take fowl by night in champaign countries, much like the net used for the low-bell, both in shape, size, and meshes. To use it, they spread it on the ground, so that the nether or further end, fixed with small plummets, may lie loose thereon; then the other part being borne up by men placed at the fore ends, it is thus trailed along the ground. At each side are carried great blazing lights, by which the birds are raised, and as they rise under the net they are taken.

TRANSCENDENTAL, or **TRANSCENDENT**, something elevated or raised above other things, which passes and transcends the nature of other inferior things. Transcendental quantities, among geometers, are indeterminate ones, or such as cannot be fixed, or expressed by any constant equation; such are all transcendental curves which cannot be defined by any algebraic equation, or which, when expressed by an equation, one of the terms thereof is a variable quantity.

TRANSFUSION of BLOOD. The experiments of Dr. Blundell and other experienced physiologists had long since demonstrated the practicability of transmitting blood from one living body to another; but it is, at length, to Dr. Blundell's application of it to the human body, and to his unwearied zeal and physiological knowledge, that the profession is indebted for positive data upon which it can be undertaken with the best hopes of saving life under circumstances of appalling, but alas! frequent occurrence. The value of the operation having been lately demonstrated by several successful cases, there seemed to be wanting but one requisite for extending the benefit of this invaluable discovery into the remotest regions of professional influence. The extreme caution practised and inculcated by Dr. Blundell, shewing the danger of admitting air into the blood-vessels, sufficiently attests the necessity for an apparatus by which the operation may be conducted without incurring this risk. This has been supplied by an appendage which Mr. Read has added to his surgical syringe, and of which Dr. Blundell has been pleased to express his approbation. It consists of a double apparatus, the one receiving the blood into a tubulated funnel, the other transmitting it from the vein

of one person into that of another, *without atmospheric communication*. In neither case is it necessary to lay bare the vein, as has been usually done, the venous pipes being constructed to pass freely into the opening made by the lancet. The transfusion appendages are so small, that the parts for the two modes of operating scarcely occupy the space of a common scalpel case, and, if fitted up with the stomach and enema apparatus, will increase the size in a very trifling degree.

Directions for the Operation with Read's Apparatus.—The metallic stem to be first screwed into the stand, the funnel next upon the stem, and, thirdly, the perpendicular arm of the latter to be inserted firmly into the extremity of the syringe by a rotatory twist. The flexible tube to be then screwed to the lateral

branch of the syringe, and the silver pipe inserted into the socket at the other extremity. The apparatus being thus adjusted, the surgeon should pump a few ounces of water through it, keeping the point of the pipe immersed in the fluid, when, if he observes any bubbles of air rise, he must fix the different parts closer until no air is admitted. The whole should now be plunged into a basin of warm water for a minute or two, and being placed betwixt the person who supplies the blood and the patient, a ligature is to be put around the arm, and the blood drawn by a free incision into the funnel. An opening being made into a vein of the patient's arm, (the limb kept steady and unmoved, to preserve the relative position of the internal and external openings, as well as to prevent the cellular tissue from slipping over the orifice in the vein) the operator gives three or four short strokes of the piston, which expels the small quantity of air contained in the tube, without occasioning the expenditure of more than a few drachms of blood. The pipe is to be immediately introduced into the vein, and the shield pressed against the surface of the arm by the fingers of an assistant, whilst the operator proceeds to throw in the blood by jets. Dr. Blundell recommends the piston to be drawn up only one-fourth its length, which will be found to throw in about a drachm of blood at a stroke. The surface of the blood in the funnel must not be allowed to sink below a line drawn in the lower part of its interior, lest air should be admitted with the fluid.

To convey blood from one person to another without atmospheric communication, the tube with the cylindrical socket, being armed with a silver pipe, is to be inserted into the extremity of the syringe, and the pipe passed into a vein (in the direction of the fingers) of the right arm of the person who is to furnish it, and whose arm is to be tied up as in the former case. A few strokes of the piston (as before directed) throws out a small quantity of blood, and expels the air in the tubes, when the pipe of the tube screwed to the side-branch of the syringe is to be passed into a vein (in the direction of the heart) of the left arm of the patient, and the quantity of blood injected may be measured by counting the strokes of the piston, reckoning one drachm at each jet. The patient should recline upon the back, with the left arm near the edge of the bed; the person losing the blood should sit on a *very low* seat close to the bedside and with his back to the operator, who stands with the pump in his left hand sufficiently distant from both parties to keep the tubes as nearly straight as possible, one nearly horizontal, the other almost perpendicular. The syringe should be very clean when used, and the assistants are required to keep the pipes firmly in the veins, during the operation.

TRANSIT, in Astronomy, signifies the passage of any planet just by or over a fixed star, or the sun; and of the moon in particular covering or moving over any planet.

TRANSITION, in Music, the softening a distinct interval by the introduction of intermediate sounds. In harmony, transition is the changing the genus or mode in a sensible but regular manner.

TRANSITION Rocks, are particularly distinguished as being the lowest in which fossil remains of animals or vegetables are found; they may be regarded as ancient records imprinted with the natural history of the first inhabitants of the globe.

TRANSMUTATION, in Geometry, denotes the reduction or change of one figure or body into another of the same area or solidity, but of a different form; as, a triangle into a square, a pyramid into a parallelopiped, &c. In the higher geometry, transmutation is used for the converting a figure into another of the same kind and order, whose respective dimensions in an equation admit of the same tangents, &c. In alchemy and metallurgy, transmutation signifies the turning of one metal into another, so as entirely to change its nature.

TRANSOMS, certain beams or timbers extended across the sternpost of a ship, to fortify her after-part, and give it the figure most suitable to the service for which she is calculated.

Helm-port TRANSOM, that which is at the head of the sternpost, and forms the upper part of the gun-room ports.

Wing TRANSOM, the next below, and forming the lower-part.

Deck TRANSOM, that whereon all the lower deck planks are rabbeted. The 1st, 2nd, 3d, transoms, &c. are respectively below the preceding.

TRANSOM Knees, are strong pieces of curved timber, which connect the ship's quarter to the transoms, being bolted to the latter and to the after timbers. See **KNEES**.

TRANSOM, among Builders, denotes the piece that is framed across a double light window.

TRANSOM, among Mathematicians, signifies the vane of a cross-staff, or a square whereon it slides, &c.

TRANSPARENCY, a quality in certain bodies, by which they give passage to the rays of light.

TRANSPORT.—See **SHIP**.

TRANSPORT Office, a department under government directed by commissioners, who charter vessels and appoint officers for the conveying troops to or from this country; they are also to provide accommodation and provision for all prisoners of war, to regulate their exchange by cartel, &c.

To TRANSPORT a Ship, is to move her by means of hawsers, anchors, &c. from one part of a harbour to another.

TRANSPORTATION, the act of conveying or carrying a thing from one place to another.

TRANSPORTATION, is a kind of punishment, or more properly an alleviation or commutation of punishment, for criminals convicted of felony; who for the first offence, unless it is an extraordinary one, are generally transported to the plantations, (at present to New South Wales), there to bear hard labour for a term of years, within which if they return, they are executed without further trial than identifying their persons.

TRANSPOSITION, in Algebra, the bringing any term of an equation over to the other side.

TRANSUBSTANTIATION, in Theology, the conversion or change of the substance of the bread and wine in the eucharist, into the body and blood of Jesus Christ, which the Romish church holds is wrought by the consecration of the priest. This is a main point in the Romish religion, and is rejected by the Protestants, the former maintaining the transubstantiation to be real, the latter only figurative; interpreting the text, *Hec est corpus meum*, "this signifies my body;" but the council of Trent stood up strenuously for the literal sense of the verb *est*, and say expressly that in transubstantiation the body and blood of our Lord Jesus Christ are truly, really, and substantially, under the species of bread and wine.

TRANSVERSE MUSCLES, in Anatomy, are certain muscles arising from the transverse processes of the vertebrae of the loins.

TRAP, is derived from the Swedish word *trappa*, a stair. It is applied, in geology, chiefly to such rocks as are frequently seen rising in regular order above one another in the form of stairs, as basalt. The chief trap rocks are *horne blande*, which

is subdivided into granular hornblende, and hornblende slate. There is also hornblende mixed with felspar, of which greenstone and greenstone slate are common subdivisions. Also hornblende mixed with mica. The transition trap consists of greenstone and amygdaloid.—Trap also signifies a snare, contrived to catch men, animals, birds, &c.

TRAPEZIUM, in Geometry, a plane figure contained under four unequal right lines.

TRAVELLER, one or more iron thimbles, with a rope spliced round them, sometimes forming a kind of tail, but more generally a species of grommet, and used on various occasions.

TRAVELLING BACK STAYS, are so denominated from their having a traveller upon the top-mast, which slides down as the top-sail is lowered, thereby confining the principal support of the back-stay to that part of the mast immediately above the top-sail-yard. See **BACKSTAY**.

TRAVELLING Martingale, a similar contrivance adapted to a martingale, to support the jib-boom in that particular part where the jib-tack is fixed. See **MARTINGALE**.

TRAVERSE, or **TRANSVERSE**, in general denotes something that goes athwart another; that is, crosses, and cuts it obliquely.

TRAVERSE, in Law, signifies sometimes to deny, sometimes to overthrow or undo a thing, or to put one to prove some matter; much used in answer to bills in chancery; or it is that which the defendant pleads or says in bar, to avoid the plaintiff's bill either by confessing and avoiding, or by denying and traversing the material part thereof.

TRAVERSE an Indictment, is to take issue upon the chief matter, and to contradict or deny some point of it. A traverse must be always made to the substantial part of the title. Where an act may indifferently be intended to be at one day or another, there the day is not traversable.

TRAVERSE SAILING, is used when a ship having set sail from one port towards another, whose course and distance from the port sailed from is given or known, is by reason of contrary winds, or other accidents, forced to shift and sail on several courses, which are to be brought into one course, to learn after so many turnings and windings the true course and distance made from the place sailed from, and the true point or place where the ship is; that so, the wind coming fair, it may be known how afterwards to shape a course for the place intended. This may be performed geometrically two ways; the first by drawing new meridians through the extremity of every course, parallel to the first meridian, or north and south line, at first made, and setting off every course at sixty, as if it were a question in plain sailing; you may also let fall perpendiculars to every new meridian, from the point that the ship sailed to

upon that course; by which you have the course, distance, difference of latitude, and departure, to every course. To work a traverse by the tables of difference of latitude and departure, make a little table with six columns; the first for the course, the second for the distance, the third for the northing, the fourth for the southing, the fifth for the easting, and the sixth for the westing. Then find the difference of the latitude and the departure to every course, and set them in their proper columns; as where the course is northerly, set the difference of latitude under northing, or in the north column; and where the course is southerly, set the difference of latitude in the south column. Again, where the column is easterly, set the departure in the east column, and when westerly set it in the west column; then adding up each column by itself, subtract the north and south columns, the less from the greater, the remainder is the northing or southing made good; then have you the difference of latitude and the departure, given to find the course and distance. This is the principal use those tables are intended for, and the way of working a traverse hereby is equal to the best for exactness, and superior in point of expedition.

TRAVERSE Board, a thin circular piece of board, marked with all the points of the compass, and having eight holes bored in each, and eight small pegs hanging from the centre of the board. It is used to determine the different courses run by a ship during the period of a watch, which is performed by sticking one peg into the point on which the ship has run each half hour. This implement is particularly useful in light and variable winds.

TRAVERSE Table, is the same with a table of difference of latitude and departure, being only the difference of latitude and departure ready calculated to every degree, point, half point, and quarter point of the quadrant; and for any distance under one hundred miles, though it may conveniently serve for greater distances, by taking their halves, thirds, fourths, &c. and doubling, tripling, and quadrupling, &c. the difference of latitude and departure found to those parts of the distance. This table is one of the most necessary things a navigator has occasion for; for by it he can readily deduce all his courses and distances run in the space of twenty-four hours, into one course and distance; whence the latitude he is in, and his departure from the meridian, may be found.

TREADMILL. This is an invention of the Chinese, and is used to raise water for the irrigation of the fields. Calpurn are condemned to this labour, the mode of working is very simple, and will be seen by looking at the figure. The treadmill lately introduced into the prisons in Great Britain is of a more complicated construction. It is the invention of Mr. Cubitt, of Ipswich. The engraving exhibits that erected at Brixton. This

Chinese Tread Mill.

wheel is exactly similar to a common water-wheel; the tread-boards upon its circumference are, however, of considerable length, so as to allow sufficient standing room for a row of from

English Tread Mill.

ten to twenty persons upon the wheel. Their weight, the first moving power of the machine, produces the greatest effect when applied upon the circumference of the wheel at or near the level

of its axle; to secure therefore this mechanical advantage, a screen of boards is fixed up in an inclined position above the wheel, in order to prevent the prisoners from climbing or stepping up higher than the level required. A hand rail is seen fixed upon this screen, by holding which they retain their upright position upon the revolving wheel; the nearest side of which is exposed to view in the plate, in order to represent its cylindrical form much more distinctly than could otherwise have been done. In the original, however, both sides are closely boarded up, so that the prisoners have no access to the interior of the wheel, and all risk of injury whatever is prevented.—By means of steps, the gang of prisoners ascend at one end; and when the requisite number range themselves upon the wheel, it commences its revolutions. The effort then to every individual is simply that of ascending an endless flight of steps, their combined weight acting upon every successive stepping board, precisely as a stream of water upon the float boards of a water-wheel. During this operation each prisoner gradually advances from the end at which he mounted towards the opposite end of the wheel, from whence the last man taking his turn descends for rest (see the engraving), another prisoner immediately mounting as before, to fill up the number required, without stopping the machine. The interval of rest may then be proportioned to each man by regulating the number of those required to work the wheel with the whole number of the gang; thus, if twenty out of twenty-four are obliged to be upon the wheel, it will give to each man intervals of rest amounting to twelve minutes in every hour of labour. Again, by varying the number of men upon the wheel, or the work inside the mill, so as to increase or diminish its velocity, the degree of hard labour or exercise to the prisoner may also be regulated. At Brixton, the diameter of the wheel being five feet, and revolving twice in a minute, the space stepped over by each man is 2193 feet, or 731 yards per hour. At page 324 the reader will find a description and engraving of another species of treadmill.

TREASON, in Law, is divided into high treason and petty treason. High treason is defined to be an offence committed against the security of the king or kingdom, whether it be by imagination, word, or deed; as, to compass or imagine the death of the king, queen, or prince, or to deflower the king's wife, or his eldest daughter unmarried; or his eldest son's wife; or levy war against the king in his realm, adhere to his enemies, counterfeit his great seal, privy seal, or money, or wittingly to bring false money into his realm counterfeited like the money of England, and utter the same, to kill the king's chancellor, treasurer, justices of either bench; justices in eyre, of assize, or of oyer and terminer, being in their place doing his office, forging the king's sign manual or privy signet, privy seal or foreign coin current here, or diminishing or impairing current money. In this case of treason, a man shall be hanged, drawn, and quartered, and forfeit his lands and goods to the king. 25 Ed. III.

TREASON, Petit. Whenever a wife murders her husband, a servant his master or mistress, or an ecclesiastic a prelate, or to whom he owes obedience, every one of these offences is *petit treason*.—As every *petit treason* implies a murder, it follows, that the mere killing of a husband, master, or prelate, is not always *petit treason*; for if there are not such circumstances in the case of killing one of these persons as would have made it murder in the case of killing any other person, it does not amount to this offence. There can be no accessory in high treason. And it seems to be always agreed, that what would have made a man an accessory before the fact in any other felony, makes him a principal in high treason.

TREASURE TROVE, is where any money or coin, gold, silver, plate, or bullion, is hidden in the earth, or other private place, the owner being unknown; in which case the treasure belongs to the king, or some other who claims by the king's grant or by prescription. But if he that hid it is known or afterwards found out, the owner and not the king is entitled to it. If it is found in the sea or upon the earth, it does not belong to the king, but to the finder if no owner appear.

TREASURER, an officer to whom the treasure of a prince or corporation is committed to be kept, and duly disposed of.

TREATY, a covenant between several nations, or the several articles or conditions stipulated and agreed upon between sovereign powers.

TREE, the first and largest of the vegetable tribe, consisting of a trunk, out of which spring forth branches and leaves.

TREE-NAILS, certain long cylindrical wooden pins, employed to connect the planks of the ship's side and bottom to the corresponding timbers, and are justly esteemed superior to spike nails or bolts, which are liable to rust and loosen; the thickness of the tree-nails is usually proportioned to the length of the ship, allowing one inch to every hundred feet.

TREFOIL, in Architecture, is the ornamenting of an arch in a particular manner. In Agriculture, trefoil is a valuable grass very generally cultivated.

TRENCHES, in Fortification, are ditches cut by the besiegers, that they may approach more securely to the place attacked, whence they are also called lines of approach. The tail of the trench is the place where it was begun, and its head is the place where it ends. The trenches are usually begun or opened in the night time; sometimes within musket-shot, and sometimes within half or whole cannon shot of the place. They are carried on in winding lines, nearly parallel to the works of the fortress, so as not to be in the view of the enemy, nor exposed to the enemy's shot. The workmen employed in the trenches are always supported by a number of troops, to defend them against the sallies of the besieged: the pioneers sometimes work on their knees, and are usually covered with mantlets or faucissons; and the men who support them lie flat on their faces, in order to avoid the enemy's shot.

TREND, (To) to incline, speaking of a coast, as, "The land trends to the south-west."

TREPAN, in Surgery, a circular saw, by means of which the operation called trepanning is performed. It bears a strong resemblance to a whimble or centre bit, and is worked in an almost similar manner.

TRESPASS, is any transgression of the law, under treason, felony, or misprision of either.

TRESTLE TREES, two strong bars of timber fixed horizontally on the opposite sides of the lower-mast head, to support the frame of the top and the weight of the top-mast.

TRET, in Commerce, an allowance made for the waste or the dirt that may be mixed with any commodity, which is always four pounds in every hundred and four pounds weight.

TRIAL, the proceeding of a court of law when the parties are at issue, such as the examination of witnesses, &c. to enable the court, deliberately weighing the evidence given on both sides, to draw a true conclusion, and administer justice accordingly.

TRIANGLE, in Geometry, a figure bounded or contained by three lines or sides, and which consequently has three angles from whence the figure takes its name.

TRIANGULA, The Triangles. The poets feign that Jupiter assigned the island of Sicily a place in the heavens, under the figure of a triangle. Hevelius has added to Jove's labour by introducing another triangle in this asterism. The old triangle is also said to owe its origin to the Delta in Egypt; both of these figures are easily distinguished by the stars on which they are formed, as well as their position relatively to Andromeda, Cepheus, and Aries.—*Boundaries and Contents.* North by Andromeda, west by Andromeda and Pisces, south by Aries, and east by Musca and Perseus. There are sixteen stars in this constellation, three of which are of the fourth magnitude and the remainder of inferior magnitudes.

TRIANGULAR COMPASSES, are such as have three legs or feet whereby to take off any triangle at once, much used in the construction of maps, globes, &c.

TRIANGULAR NUMBERS, are a kind of polygonal numbers, being the sums of arithmetical progressions which have 1 for the common difference of their terms. Thus, from these arithmeticals, 1, 2, 3, 4, 5, 6, are formed the triangular numbers, 1, 3, 6, 10, 15, 21, or the third column of the arithmetical triangle above mentioned.

TRIANGULAR Canon, the tables of artificial sines, tangents, secants, &c.

TRIANGULAR Quadrant, is a sector furnished with a loose piece whereby to make it an equilateral triangle. The calendar is graduated thereon with the sun's place, declination, and other useful lines; and by the help of a string and a plummet, and the divisions graduated on the loose piece, it may be made to serve for a quadrant.

TRIANGULUM AUSTRALE, the *Southern Triangle*, one of the constellations situated on the Antarctic circle, contains five stars, viz. one of the 2d magnitude, two of the 3d, &c.

TRIBOMETER, an instrument invented for estimating the friction of metals.

TRICE, (To) to haul or tie up by means of a small rope or line.

TRICHECHUS, **WALRUS**, a genus of quadrupeds of the order bruta. It is principally found in the high latitudes of the northern ocean. These animals are gregarious, and are often seen upon floating masses of ice in immense numbers, the greater part sleeping, but some always on the watch to give notice of approaching danger. They are harmless when not provoked, but some accounts represent them as highly formidable in a state of irritation, the efforts of many being combined against the enemy, and fastening with their teeth against the boats, to make holes in them, or draw them to the bottom. Others represent them as less agitated by the fury of passion, and as inclined more to flight than revenge; adding, that they are terrified by the slightest flash, and even the pointing of a musket will drive them in a moment out of sight. Their tusks serve the purposes of aiding their movements upon the ice, into which they are stuck, and on which they thus secure their hold, and sometimes drag on their unwieldy bodies. The tusks are convertible to the purposes of ivory, and these animals are destroyed for the profit derived partly from these tusks, but principally for the sake of their oil, of which a full-grown walrus will yield a butt. The skin may be manufactured into a very strong leather. The affection between the female and its young one, for it has seldom more than one at a birth, is such, that they are said never to separate, and that when one is killed, the survivor refuses to quit the dead body, and is considered by the hunter as his secure prey. The walrus has been called, with little resemblance to justify the name, the sea-horse; it is more similar to a cow—but most of all to a seal. The whale-tailed manati, inhabits the seas between Kamptschatka and America. These animals live in families, generally consisting of a male and female, and two young ones of different ages, and the attachment of the male to the female is so great, that he will defend her when attacked to the last extremity; and if she happens to be destroyed and dragged to the shore, he will swim for some days off the fatal and detested spot. The manati approaches very nearly to the cete tribe, and its feet are little more than pectoral fins. It attains the immense length of twenty-seven feet, and the weight of four tons. In winter it is extremely lean, and its ribs may be distinctly numbered. It will, when pierced with the harpoon, sometimes adhere to rocks with its feet with uncommon tenacity, and when forced from them by a cord drawn by thirty men or more, is found to have left part of the skin of the feet behind. When any individual is harpooned, others are stated to swim to its aid, endeavouring some to overturn the boat, others to break the cord, and others again by blows with their tails striving to dislodge the harpoon. Their sounds resemble the snorting of a horse. They are never seen on land.

TRICING LINE, a small cord generally passing through a block or thimble, and used to hoist up any object to a higher station, in order to render it less inconvenient, such are the tricing lines of the yard tackles, &c.

TRICK, the same as spell with regard to steering the ship. See the article **SPELL**.

TRIFOLIUM, **TREFOIL**, or *Clower*, a genus of plants of the class diadelphia, and order decandria, and in the natural system ranging under the 32d order papilionaceæ. The flowers are generally in round heads; the pod is scarcely longer than the calyx, univalve, not opening, deciduous. The leaves are three together: 51 species.

TRIGONOMETRY. The business of this important science is to find the angles, where the sides are given; and the sides of their respective ratios, when the angles are given; and to find sides and angles, when sides and angles are partly given. To effect this, it is necessary not only that the peripheries of circles, but also certain right lines in and about circles, be supposed divided into certain numbers of parts. The ancients, feeling the necessity of such a pre-division, portioned the circles into 360 equal parts, which they called degrees; each degree was again divided into 60 equal parts, called minutes;

and each minute comprised 60 equal parts called seconds. The moderns have improved upon this division by the addition of a nonius, or vernier, which may be carried to any extent, but is usually limited to decimating the seconds; noting each tenth part thereof. It would have been found a considerable convenience in mathematics, if the circle had been divided into centesimal parts, particularly in trigonometrical operations; thus making every quadrant to consist of 100 degrees, each degree of 100 minutes, and each minute of 100 seconds; there can, indeed, be no doubt that all the arithmetical calculations relating to the periphery, as well as to the sines, tangents, secants, signs, tangents, radii, chords, and complements, would by this reformation have been simplified. See the words **MENSURATION**, **ACCESSIBLE DISTANCE**, **HEIGHTS** and **DISTANCES**, &c.

TRILLION, in Arithmetic, a billion of billions.

TRIM, the state or disposition of the ballast, cargo, masts, &c. by which a ship is best equipped for the several purposes of navigation.

The Taim of the Hold, implies the arrangement of the materials therein, by which a ship is either brought by the head or stern, or depressed in the water to a sufficient depth to carry sail well, and advance rapidly. As the stowage of the hold, or the disposition of the several articles of the cargo, considerably affects the ship's motion and stability, it will be necessary to give a general idea of the action that supports it, and the action of the fluid on the floating body.

First, we may consider the whole weight of any body united in its centre of gravity: so that if it were suspended by a line fastened to this centre, the line would hang in a perpendicular position, as directed through the centre of gravity to the centre of the earth. A body which floats in a fluid is not, however, supported by its centre of gravity, but by the compression of the surrounding filaments of water; and each of these being considered as infinitely small, will act upon a very minute portion of the surface of the floating body with regard to the specific gravity, and conform to a principle applicable to all fluids, in proportion to the height of these filaments, viz. that the weight of a column of any fluid will be in proportion to the specific gravity of the fluid and the height of the column multiplied by its base. But as heavy bodies endeavour by their gravity to approach the centre of the earth in a vertical line passing through that centre, so the pressure of fluids endeavours to carry bodies in a vertical line tending from the centre of the earth towards the surface, and passing through the centre of gravity of the submerged part which forces them towards the surface. So in any submerged body at rest, these two opposite forces coincide in the same vertical, acting in a direction quite contrary to each other. According to this theory, it appears that the stability or trim of a ship chiefly depends upon her construction, in considering the bottom to be homogeneous. This, however, can only happen when her cargo consists of the same materials throughout, as with corn, salt, or any species heaved in bulk, and when her hold is entirely filled: for if the ship has not sufficient breadth to resist the effort of the wind upon her sails, or if she is built too high or too sharp in the floor, her gravity will be too high, and she will be very crank, i. e. apt to overturn. But as the stiffness of a ship, or quality to carry sail without damage of overturning, depends very much on the stowage of the hold, the centre of gravity may thereby be considerably lowered, by which her stability will be increased in proportion. It is a general maxim among mariners, that a ship will not carry sufficient sail till she is laden so deep that the surface of the water may glance on her extreme breadth amid-ships. She must therefore have a great deal of weight, as ballast, &c. to bring her to this situation, which is called a good sailing trim. With regard to the quality, weight, and stowage of the ballast, there are also several circumstances to be particularly considered. If the centre of gravity be placed too high, the ship will be rendered incapable of carrying a sufficient quantity of sail, and if it be placed too low, she will be in danger of rolling away her masts. When it is placed too far forward, the vessel will pitch and labour heavily; and when too far aft, she will occasionally be exposed to the dangerous circumstance of a peeping sea. These extremes being carefully avoided, it remains to proportion the contents of every part of the hold to its capacity, and to place the lightest materials uppermost,

TRIM of the Masts, denotes their position with regard to the ship and to each other, whether near or distant, far forward or much aft, erect or raking.

TRIM of the Sails, signifies the general arrangement which is best calculated to accelerate the ship's course according to the direction of the wind. See the articles **CLOSE-MAILED**, **LARGE SAILING**, **TACKING**, &c.

If a ship were always to sail before the wind, it would be a very simple operation to trim the sails; for nothing more would be required than to dispose them so as to receive the greatest possible effort of the wind, which is evidently performed by arranging them at right angles with its direction. But when the current of wind acts more directly upon the ship's side, it necessarily falls more obliquely on the surface of the sails, so as to diminish their effort to push the ship forward, and to augment their tendency to make her incline to one side. Hence we may conclude, that an increase of the wind, when accompanied with a variation unfavourable to the ship's course, will by no means augment her velocity; because the force previously employed to push her forward will afterwards operate to overturn her, and because this impression renders it necessary to reduce the quantity of sail; the effort of which is further diminished by the obliquity of the action of the wind upon its surface. By this theory it appears, that the effect of the wind to advance the ship, decreases in proportion to its obliquity with any sail upon which it operates.

TRIM the Boat. See **Boat**.

TRIMMED SHARP, the situation of a ship's sails in a scant wind.

TRINITY HOUSE, a kind of college at Deptford, belonging to a company or corporation of seamen, who by the king's charter have power to take cognizance of those persons who destroy sea-marks, and to get reparation of such damages, and to take care of other things belonging to navigation. At present, many in the first rank of society are members of that community. The master, wardens, and assistants of the Trinity House, may set up beacons and marks for the sea, in such places near the coast or forelands as to them shall seem meet. By a statute of Queen Elizabeth, no steeple, trees, or other things standing as sea-marks, shall be taken away or cut down, upon pain, that every person guilty of such offence shall forfeit 100*l*. and if the person offending be not possessed of the value, he shall be deemed convicted of outlawry.

TRIP, a phrase implying an outward-bound voyage, particularly in the coasting navigation. It also denotes a single board in plying to windward.

TRIPPLICATE RATIO, the ratio of cubes to one another.

TRIPOLI, a mineral found sometimes in an earthy form, but more generally indurated. Its texture is earthy.

TRIPPING, the movement by which an anchor is loosened from the bottom, either by its cable or buoy-rope.

TRIPPING-LINE, a small rope serving to unrig the lower-top-gallant-yard-arm, when in the act of striking or lowering it down upon deck.

TRISECTION, or **TRISSECTION**, the dividing a thing into three. The term is chiefly used in geometry for the division of an angle into three equal parts. The trisection of an angle geometrically, is one of those great problems whose solution has been so much sought by mathematicians for these two thousand years, being in this respect on a footing with the quadrature of the circle, and the duplicature of the cube angle.

TRITICUM, **WHEAT**, a genus of plants of the class triandria, and order digynia, and in the natural system ranging under the fourth order gramina.

TROCHILUS, *Humming Bird*, a genus of birds belonging to the order of picæ. There are sixty-five species, none of which are natives of Britain: they are all remarkable for the beauty of their colours, and most of them for the smallness of their size, though some are eight or nine inches in length. They are divided into two families, viz. those with crooked bills, and those with straight bills.

TRONAGE, the mayor and commonalty of the city of London are ordained keepers of the beams and weights for weighing merchants' commodities, with power to assign clerks, porters, &c. of the great beam and balance, which weighing of goods and wares is called *tronage*.

TROPHY, **TROPEUM**, among the ancients, a pile or heap of arms of a vanquished enemy, raised by the conqueror in the most eminent part of the field of battle. The trophies were usually dedicated to some of the gods, especially Jupiter. The name of the deity to whom they were inscribed was generally mentioned, as was that also of the conqueror.

TROPICS, two imaginary lines upon the globe parallel to the equator, and at 23½ degrees distance on each side of it; they form the boundaries of the sun's declination north and south.

TROUGH, a name given to the hollow or interval between two waves, which resembles a broad and deep trench perpetually fluctuating. As the setting of the sea is always produced by the wind, it is evident that the waves, and consequently the trough or hollow space between them, will be at right angles with the direction of the wind; hence a ship rolls heaviest when she lies in the trough of the sea.

TROUT, a very valuable river fish, too well known to need description.

TROVER, is the remedy prescribed by the law, where any person is in the possession of the property of another, which he unlawfully detains.

TROY WEIGHT, one of the most ancient of the different kinds used in Britain. The pound English troy contains 12 ounces, or 5760 grains.

TROY WEIGHT, *Scots*, was established by James VI. in the year 1618, who enacted that only one weight should be used in Scotland, viz. the French troy stone of 16 pounds, and 16 ounces in the pound. The pound contains 7600 grains; and is equal to 17 oz. 6 dr. avoirdupois. The oz. or 112 lb. avoirdupois, contains only 108 lb. 2½ oz. of this weight, though generally reckoned equal to 104 lb. Though prohibited by the articles of union, it is still used in weighing iron, hemp, flax, most Dutch and Baltic goods, meal, butcher's meat, unwrought pewter and lead, and some other articles.

TRUCE, in War, denotes a suspension of arms, or a cessation of hostilities between two armies, in order to settle articles of peace, bury the dead, or the like.

TRUCKS, pieces of wood of various forms, and used for different purposes, as

TRUCKS of a Gun Carriage. See the article **CARRIAGE**.

TRUCKS of the Mast-Head, circular pieces of wood, fixed as a cap on the top-gallant-mast heads. They are generally furnished with two or more small pulleys through which the pendant and signal-halliards are reeved. They are also called *acorns*.

TRUCKS of the Parrels, are spherical pieces of wood, having a hole through them, in which is inserted the rope of the parrel. See the article **PARREL**.

TRUCKS of the Flag Staff, are pieces resembling an oblate spheroid.

TRUCKS of the Shrouds, or *Seizing Trucks*, are pieces something resembling those of the parrels, except that they are scored round the outside, to receive a seizing, and are fixed to the shrouds, in order to lead the running rigging and prevent it from hanging. The intention of these is to guide the sailors to the particular rope which, especially in the night, might otherwise be mistaken for some other of the same size.

TRUFFLES, in Natural History, a kind of subterraneous puff-ball, being a species of fungi, which grows under the surface of the earth.

TRUMPET, the loudest of all portable wind instruments, and consisting of a folded tube generally made of brass, and sometimes of silver.

TRUMPET Hearing, is an instrument to assist the hearing of persons who are deaf. Instruments of this kind are formed of tubes, with a wide mouth, and terminating in a small canal, which is applied to the ear. The form of these instruments evidently shows how they conduce to assist the hearing, for the greater quantity of the weak and languid pulses of the air being received and collected by the large end of the tube, are reflected to the small end, where they are collected and condensed; thence entering the ear in this condensed state, they strike the tympanum with a greater force than they could naturally have done from the ear alone. Hence it appears that a speaking trumpet may be applied to the purpose of a hearing trumpet.

by turning the wind end towards the sound, and the narrow end to the ear.

TRUMPET, Marine, a kind of monochord, consisting of three tables which form its triangular body. It has a very narrow neck, with one thick string, mounted on a bridge, which is firm on one side, and tremulous on the other. It is struck with a bow by the right hand, while the thumb of the left is pressed on the string.

TRUMPET, Speaking, is a tube of considerable length, viz. from 6 feet to 12, and even more, used for speaking with, to make the voice heard to a greater distance. In a trumpet of this kind the sound in one direction is supposed to be increased, not so much by its being prevented from spreading all around, as by the reflection from the sides of the trumpet. The figure best suited for the speaking trumpet is that which is generated by the rotation of a parabola about a line parallel to the axis.

TRUNCATED, in general, is an appellation given to such things as have, or seem to have, their points cut off.

TRUNDLE, in rural economy, a sort of truck having two handles at one extremity, and two low wheels at the other, by which means it is trundled before the person using it. In conveying articles of great weight, but of small bulk, this simple machine is found very convenient.

TRUNDLE Shot, an iron bar called a shot, about seventeen inches long, and sharp-pointed at the ends, having a round ball of lead cast upon it, at a hand's breadth from the extremities.

TRUNKS, FIRE, wooden funnels fixed in fire-ships, under the shrouds, to convey the flames to the masts, rigging, and sails.

TRUNNIONS, the two knobs or arms which project from the opposite side of a piece of artillery, and serve to support it in the carriage.

TRUSS, is also used for a sort of bandage or ligature made of steel, or the like matter, wherewith to keep up the parts in those who have hernias or ruptures. A bale of goods is also called a truss.

TRUSS of Flowers, is used by florists to signify many flowers growing together on the head of a stalk, as in the cowslip, auricula, &c.

TRUSS, among Mariners, signifies a machine employed to pull a lower yard close to its mast, and retain it firmly in that position. As the truss is generally used instead of a parrel, it is rarely employed except in flying top-gallant sails, which are never furnished with parrels. It is no other than a ring or traveller, which encircles the mast, and has a rope fastened to its after-part, leading downward to the top or decks; by means of which the truss may be straitened or slackened at pleasure. The halliards of the top-gallant sails being passed through this ring, and the sail being hoisted up to its utmost extent, it is evident that the yard will be drawn close to the main-mast by pulling down the truss close to the upper part of the sail; for without the truss the sail and its yard would be blown from the mast so as to swing about by the action of the wind and the rolling of the vessel, unless the yard were hoisted close up to the pulley wherein the halliards run, which seldom is the case in flying top-gallant-sails, because they are usually much shallower than those which are fixed or standing.

TRUSS Tackle, a combination of pulleys fixed to the end of the truss pendants to bowse them taught.

TRUST, is a right to receive profits of land, and to dispose of the land in equity. And one holding the possession, and disposing of it at his will and pleasure, are signs of trust.

TRUSTEE, one who has an estate or money put or trusted in his hands for the use of another.

TRYING, the situation in which a ship lies nearly in the trough or hollow of the sea in a tempest, or it is the act of lying to in a storm, which may be performed under any of the courses reefed, if requisite, or even under bare poles, the helm being lashed a-lee. In trying, as well as in scudding, the sails are always reduced in proportion to the increase of the storm. Thus, in the former state a ship may lie by the wind under a whole main-sail, a whole fore-sail, or a whole mizzen; or under any of those sails, when diminished by the reef or balance. As the least possible quantity of sail used in scudding are the goose-wings of the fore-sail, so in trying, the smallest portion is generally the mizzen stay-sail, or main stay-sail; and, in either state, if the storm be

excessive, she may lie with all the sails furled, or, according to the sea phrase, under bare poles. The intent of spreading a sail at this time is to keep the ship more steady, and by pressing her side down in the water, to prevent her from rolling violently, and also to turn her towards the direction of the wind, so that the shock of the waves may fall more obliquely on her flank than when she lies along the trough of the sea. While she remains in this situation, the helm is fastened close to the lee-side, or, in the sea language, hard a-lee, to prevent her as much as possible from falling off. But as the ship is not then kept in equilibrium by the effort of her sails, which at other times counterbalance each other at the head and stern, she is moved by a slow but continual vibration, which turns her head alternately to windward and to leeward, forming an angle of three or four points in the interval. That part where she stops in approaching the direction of the wind, is called her coming to, and the contrary excess of the angle to leeward is termed her falling off. Thus, suppose the wind northerly, and a ship trying with her starboard side to windward; if, in turning her head towards the source of the wind she arrives at N. W. $\frac{1}{2}$ E. or N. 39° W. and then declines to the leeward as far as W. $\frac{1}{2}$ S. or S. 84° W. the former will be called her coming to, and the latter her falling off.

TRY-SAIL, a sail used by cutters, luggers, sloops, &c. in lieu of their main-sail during a storm. *Try Sail*, is also the name of a sail on board of a snow, which see.

TUB, is a kind of measure to denote the quantity of various things. A tub of tea, is about 60 pounds; a tub of camphor, from 56 to 80 pounds; and a tub of vermilion, from 300 to 400 cwt.

TUB, MATCH, the half of a cask, having notches sawn in its edge, wherein the lighted matches are placed during action, the bottom being covered with water to extinguish any sparks which may fall from the match.

Topsail Halliard Tubs, similar to half casks, in which the topsail halliards are coiled.

Grog Tub, a half cask set apart for mixing the daily allowance of spirits with water, prior to its being served out to the ship's company.

TUBE, in general, pipe, conduit, or canal; a cylinder, hollow within, either of lead, iron, wood, glass, or other matter, for the air, or some other fluid, to have a free passage or conveyance through.

TUBE, in Astronomy, is sometimes used for a telescope, or, more properly, for that part into which the lenses are fitted, and by which they are directed and used.

TUBER, or **TUBERCLE**, a kind of round turgid root, in the form of a knob or turnip. The plants which produce such roots are hence denominated *tuberous*. Tuber is an old Latin name for any sort of excrescence, its derivation being from *tumere*, to swell. It is applied to several things of the fungus tribe.

TUCK, that part of a ship where the ends of the bottom planks are collected together, immediately under the stem or counter.

A *Square Tuck*, is terminated above by the wing transom, and below and on each side by the fashion-pieces.

TUFAS, beds of lime deposited on vegetables, which by their destruction give great lightness and porousness to the mass.

TUISCO, a fabulous deity among the northern nations, from whom our Tuesday derives its name, that being the day on which his worship was more particularly celebrated.

TULIPA, **TULIP**, a genus of plants, of the class hexandria and order monogynia, and in the natural system ranging under the 10th order coronariae.

TUMBLING HOME, that part of a ship's side which falls inward above the extreme breadth, so as to make the ship gradually narrower from the lower deck upwards. In all old sea-books, this narrowing of a ship from the extreme breadth upwards is called housing-in.

TUMOUR, or **TUMOR**, in Medicine and Surgery, a preternatural rising or hard swelling on any part of the body.

TUN, or **TON**, originally signifies a large vessel or cask, of an oblong form, biggest in the middle, and diminishing towards its two ends, girt about with hoops, and used for stowing several kinds of merchandise, for convenience of carriage; as, brandy, oil, sugar, skins, hats, &c. This word is also used for

certain vessels of extraordinary bigness, serving to keep wine for several years.

TUN, is also a certain measure for liquids, as wine, oil, &c.

TUN, is also a certain weight whereby the burdens of ships, &c. are estimated.

TUNE, or **TONE**, in Music, that property of sounds whereby they come under the relation of acute and grave to one another.

TUNGSTEN, a mineral found in Sweden, of an opaque white colour and great weight; whence its name tungsten or ponderous stone. This ore was analyzed by Scheele, who found that it was composed of lime and a peculiar earthy-like substance, which from his properties he called tungstic acid. The basis of the acid was found to contain a metal which was named tungsten, and which was obtained from the acid mixed with charcoal.

TUNICA, a kind of waistcoat or under garments, in use among the Romans.

TUNNEL, a large subterraneous arch driven through a hill for the passage of boats in a canal continued through the same.

TURBAN, the head dress of most of the eastern and Mahometan nations. In the adjustment of the turban much taste is displayed. In the folds, the dimensions, and colours of the turban, the rank and dignity of the wearer may frequently be known. The Emirs, who trace their descent from Mahomet, have green turbans, while the others are ordinarily red, with a white sash. Persons of distinction have frequent changes of turbans. The turban of the grand signor is as large as a bushel, adorned with three plumes of feathers, and enriched with diamonds and precious stones. It is so highly respected by the Turks, that they scarcely presume to touch it. That of the grand vizir has two plumes, superior in size to those of any inferior officer.

TURBOT, a well-known fish, uniformly held in high estimation.

TURDUS, the *Thrush*, in Natural History, a genus of birds of the order passeros.

TURF, the greensward, or surface of grass land.

TURMERIC, the *Indian Saffron*. It is now cultivated in England, and in the materia medica is officially known. It is also much used in yellow dyes.

TURN of the **TIDE**, the change from ebb to flood, or the contrary.

TURN of a *Rope*, the applying it once round any body, as a timber-head, &c. in order to hold on.

TURN in the *Hawse*. See **HAWSE**.

To **TURN** in, a sea phrase implying to go to bed, as

To **TURN** Out, is to get up or out of bed.

To **TURN** in a *Dead Eye* or *Heart*, to seize the end of a shroud or stay, &c. securely round it.

To **TURN** over *Men*, to discharge them out of one ship into another.

To **TURN** the *Hands* up, to call the ship's company upon deck for any particular purpose.

TURNAMENT, or **TOURNAMENT**, a martial sport or exercise which the ancient cavaliers used to perform, to shew their bravery and address.

TURNING. See **LATHE**.

TURNING to **WINDWARD**, that operation in sailing, wherein a ship endeavours to make a progress against the direction of the wind, by a compound course inclined to the place of her destination; this is otherwise called plying or beating to windward. See the articles **BEATING** and **TACKING**.

TURNIP, a nutritious bulb-rooted plant, of which there are many sorts in cultivation by the gardeners and farmers.

TURNPIKE, a gate set up across a road, watched by an officer for the purpose, in order to stop travellers, waggons, coaches, &c. to take toll of them towards repairing or keeping the roads in repair.

TURPENTINE, a transparent sort of resinous juice, flowing either naturally or by incision from several saccous trees, such as the larch, pine, fir, &c. Turpentine is too generally known to require a particular description, either of its nature or numerous uses.

TURRETS, among the Romans, were a kind of moveable towers, driven by men towards the place of attack, and con-

taining soldiers, who were secure from the weapons of their assailants.

TUTENAG. This name is given in India to the metal zinc. It is sometimes applied to denote a white metallic compound, brought from China, called also Chinese copper, the art of making which is not known in Europe. Three ingredients of this compound may be discovered by analysis; namely, copper, zinc, and iron. Some of the Chinese white copper is said to be merely copper and arsenic.

TUTOR, one chosen to instruct children.

TUTTY, an argillaceous ore of zinc, found in Persia, formed on cylindrical moulds into tubulous pieces, like the bark of a tree, and baked to a moderate hardness.

TWICE-LAID CORDAGE, is made of eart rigging, which being untwisted, is again wrought up into ropes sufficiently strong for numerous purposes.

TWILIGHT, denotes that faint light which is reflected by means of the atmosphere before the sun rises, and after he sets.

TWINE, a kind of strong thread used in sail-making, and is of two kinds, extra for sewing the seams, and ordinary for the bolt-ropes.

TYCHONIC SYSTEM or **HYPOTHESIS**, an order or arrangement of the heavenly bodies, of an intermediate nature between the Copernican and Ptolemaic, or participating alike of them both. This system had its name and original from Tycho Brahe, a nobleman of Denmark, who lived in the latter part of the last century. This philosopher, though he approved of the Copernican system, yet could not reconcile himself to the motion of the earth; and being, on the other hand convinced the Ptolemaic scheme could not be true, he contrived one different from either. In this the earth has no motion allowed it but the annual. The Tychonic system then supposed the earth in the centre of the system, that is, of the firmament of stars, and also of the orbits of the sun and moon; but at the same time it made the sun the centre of the planetary motions, viz. of the orbits of Mercury, Venus, Mars, Jupiter, and Saturn. Thus, the sun, with all its planets, was made to revolve about the earth once a year, to solve the phenomena arising from the annual motion; and every twenty-four hours, to account for those of the diurnal motion.

TYE, a sort of runner or thick rope, used to transmit the effort of a tackle to any yard or gaff, which extends the upper part of a sail. The tye is either passed through a block fixed to the mast-head, and afterwards through another block attached to the yard or gaff, and returns to the mast-head, or the end of it is simply passed over a sheave in the mast-head, and then fastened to the said yard or gaff.

TYMPAN, among Printers, is a double frame, belonging to the press, covered with parchment, on which the blank sheets are laid in order to receive the impression.

TYMPANUM, or **TYMPAN**, in Mechanics, a kind of wheel placed round an axis or cylindrical beam, on the top of which are two levers or fixed staves, for the more easy turning the axis, in order to raise a weight required.

TYPE, among Printers, is a metallic composition cast into letters, and is a term of synonymous import. See **PRINTING**.

TYPE-METAL. The basis of type metal for printers is lead, and the principal article used in communicating hardness is antimony, to which copper and brass in various proportions are added. The properties of a good type metal are, that it should run freely into the mould, and possess hardness without being excessively brittle. The smaller letters are made of a harder composition than those of a larger size. It does not appear that our type foundries are in possession of a good composition for this purpose. The principal defect of their composition appears to be that the metals do not uniformly unite. In a piece of casting performed at one of our principal foundries, the thickness of which was two inches, one side was hard and brittle when scraped, and the other side, consisting of nearly half the piece, was soft like lead. The transition from soft to hard was sudden, not gradual. If a parcel of letter of the same size and casting be examined, some of them are brittle and hard, and resist the knife, but others may be bent and cut into shavings. It may easily be imagined that the duration and neatness of these types must considerably vary.

TYPOGRAPHY. See **PRINTING**.

U

U, or **V**, the twentieth letter of our alphabet. In numerals **V** stands for five; and with a dash added at top, thus **V**, it signifies five thousand. In abbreviations, amongst the Romans, **V. A.** stood for veterani assignati; **V. B.** viro bono; **V. B. A.** viri boni arbitratu; **V. B. F.** vir bonæ fidei; **V. C.** vir consularis; **V. C. C. F.** vale, conjux charissime, feliciter; **V. D. D.** voto dedicatur; **V. G.** verbi gratia; **Vir. Ve.** virgo vestalis; **VL.** videlicet; **V. N.** quinto nonarum.

U, as a contraction expresses *urbs* or *urbe*.

ULLAGE of a **CASK**, in Gauging, is what it wants of being full.

ULMUS, the *Elm*. Elms are forest trees well known in almost every part of England. There are several species, of which, however, only three, the common elm, wych hazel, or broad-leaved elm, and Dutch elm, grow in this country without cultivation. They are easily distinguishable, even by a common observer, from most other forest trees, by their leaves being rough, and doubly serrated at the edge.

ULTIMATE RATIOS. To avoid both the tediousness of the ancients and the inaccuracy of the moderns, Sir Isaac Newton introduced what he called the method of prime and ultimate ratios, the foundation of which is contained in the first lemma of the first book of the *Principia*.

UMBELLIFEROUS PLANTS, are such as have their tops branched and spread out like an umbrella, on each little subdivision of which there is growing a small flower; such are fennel, dill, &c.

UMBER, or **GRAYLING**, (*Salmo Thymallus*), is a fish of the salmon tribe, distinguished by having several longitudinal streaks upon its body, the first dorsal fin nearer the head than the ventral fins, the upper jaw longer than the lower one, the side nearly straight, and the tail forked. A fish of this species was caught lately in the Severn which weighed five pounds. The umber inhabits the clear and rapid streams of Europe and Siberia. These fish are so much esteemed in some parts of the continent, that they are exclusively reserved for the tables of the nobility. They are fattest in the autumn, but are best in season during the winter, particularly when the weather is cold; and they cannot be dressed too soon after they are caught. Many of the old medical writers strongly recommended umber as a wholesome fish for sick persons: they also stated that an oil prepared from its fat would obliterate freckles and other spots on the skin. By the Laplanders the intestines are frequently employed as a substitute for rennet, to coagulate the milk of the rein-deer when used for the making of cheese. These fish are in great esteem by anglers on account of their vivacity, the eagerness with which they rise at a bait, and their rapid motions through the water. They lurk close all the winter, and begin to be very active in April and May, about which time they deposit their spawn.

UMBRELLA, a well-known shade from the sun, or guard from the rain, formed by stretching silk, cotton, oil cloth, or other material, in a dome-like form over whalebone, and so constructed that it may be either spread or contracted, as circumstances may require. In Europe these conveniences have not been long in use. They were introduced from the East, where they have been known from time immemorial, but in a less elegant form than they have assumed since their importation among the western nations.

UNDECAGON, a polygon of eleven sides.

UNDULATORY MOTION, is applied to denote a motion in any fluid, by which its parts are agitated like the waves of the sea, and is particularly applied to the motion of the air in the propagation of sound.

UNEVEN NUMBER, or *Odd Number*, that which cannot be divided into two equal integral parts.

UNGULA, is the bottom part cut off by a plane passing obliquely through the base of a cone or cylinder, being thus called from its resemblance to the ungula or hoof of a horse, &c.

UNGULA, among Surgeons, a sort of hooked instrument, used to extract a dead fœtus out of the womb.

UNICIA, the 12th part of a thing.

UNICIÆ, the same as co-efficient.

UNICORN. See *MONOCEROS*.

UNIT, or **UNITY**, is the representation of any thing considered individually, without regard to the parts of which it is composed.

UNITARIANS, those Christians who believe in and worship one only self-existent God—the Father of Jesus Christ, in opposition to those who, besides the Father, worship his Son Jesus, and the Holy Ghost, and who are therefore called *Trinitarians*. The Unitarians are often called *Socinians*; but the Socinians were not Unitarians, because they paid divine worship to the Son of God.

UNITAS FRATRUM, or **UNITED BRETHREN**, a name distinguishing those Christians who are frequently called *Hamburghers* abroad, and *Moravians* at home.

UNIVERSALISTS, those who hold that all future punishment is designed for correction, and that consequently all rational beings will be ultimately rendered happy by the God of love and mercy.

UNIVERSE, a collective term signifying the assemblage of heaven and earth, with all things in and upon them.

UNLACING, the act of loosening and taking off the harness of a sail from its principal part.

UNMOORING, reducing a ship to the state of riding by a single anchor and cable, after she has been moored and fastened by two or more cables. See the articles *ANCHOR* and *MOOR*.

UNREEVING, the act of withdrawing or taking out a rope from any block, thimble, dead-eye, &c. through which it had formerly passed. See the article *REEVE*.

UNRIGGING, depriving a ship of her standing and running rigging.

UNSHIPPING, removing any piece of timber or wood from the place in which it was fitted, as, "unship the capstan bars," "unship your oars."

UNSLINGING, to take off slings, which see.

UPPER-DECK, the highest of those decks which are continued throughout the whole length of a ship.

UPPER Works, a general name given to all that part of a ship which is above the surface of the water when she is properly balanced for a sea voyage.

UPRIGHT, the situation wherein the opposite sides of a ship are equally elevated above the surface of the water, or when she neither inclines to the right nor left, with regard to the vertical position of her stem and stern post.

URANIBURGH, the name given to the celebrated observatory of Tycho Brahe, founded by him in the little island of Weenen in the Sound.

URANIUM, a mineral found in Saxony, partly in a pure and partly in a mixed state. There are two varieties of them; the first of a blackish colour, quite opaque, and tolerably hard, and with a specific gravity of about 7.5. The second is distinguished by a finer black colour, with here and there a reddish cast; by a stronger lustre, not unlike that of pit coal; by an inferior hardness, and by a shade of green, which tinges its black colour when it is reduced to powder. Uranium is of a dark gray colour; internally it is somewhat inclined to brava.

URANUS, **HERSCHEL**, or **GEORGIUM SIDUS**, the name of the new planet discovered by Dr. Herschel the 13th March, 1781. See *ASTRONOMY*.

URCHIN, **THE**, or **HEDGE-HOG**, is a small British quadruped, the upper parts of which are covered with spines, each about an inch long, and the under parts with hair. These animals are of considerable utility in several points of view. If kept, and allowed to run about rooms that are infested with leeches, cockroaches, or crickets, they will destroy the whole of them. Some persons imagine that they will devour mice, but this wants authentication. A hedge-hog, which was kept at the Angel Inn, at Felton, Northumberland, was tamed, and employed as a turnspit, and is said to have performed this

duty in every respect as well as a dog of that name. The flesh of this animal is occasionally used as food, and is said to be very delicate eating. The skin, which was frequently employed by the ancients as a clothes' brush, is now used by farmers in some parts of the continent to put on the muzzles of calves which they are about to wean, that the cow may not permit them to suck. Several of the old writers have related accounts of very extraordinary, and at the same time very absurd, medical effects from different parts of this animal. Hedge-hogs frequent most commonly the bottoms of dry ditches, where they have shelter and concealment under bushes, fern, and grass. They sleep in the day-time, and are awake during the night, when they run abroad in search of worms, snails, insects, and other food. Few creatures can be more inoffensive. When attacked, they defend themselves by rolling into a globular form, and opposing on all sides a spinous surface. There is a notion, but it is apparently unfounded, that hedge-hogs suck the milk of cows whilst lying in the fields asleep.

UREA, the constituent and characteristic matter of urine, may be obtained by the following process: evaporate by a gentle heat a quantity of human urine, voided six or eight hours after a meal, till it is reduced to the consistence of a thick syrup. In this state, when put by to cool, it concretes into a crystalline mass. Pour at different times upon this mass four times its weight of alcohol, and apply a gentle heat; a great part of the mass will be dissolved, and there will remain only a number of saline substances; pour the alcohol solution into a retort, and distil by the heat of a sand-bath till the liquid, after boiling some time, is reduced to the consistence of a thick syrup. The whole of the alcohol is now separated, and what remains in the retort crystallizes as it cools. These crystals consist of the substance known by the name of urea.

URIC ACID. Uric or lithic acid was discovered by Scheele in 1776. It is the most common constituent of urinary calculi, and exists also in human urine. It has a brown colour; is hard, and crystallizes into small scales. It has neither taste nor smell, is insoluble in cold water, but soluble in 360 parts of boiling water.

URINE. The properties of urine vary considerably, according to the constitution and health of the body, and the period when it is voided after taking food. The urine of a healthy person is of a light orange colour, and uniformly transparent. It has a slightly aromatic odour, in some degree resembling that of violets. It has a slightly acid saline bitter taste. The specific gravity varies from 1.005 to 1.033. The aromatic odour, which leaves it as it cools, is succeeded by what is called the urinous smell, which latter is converted to another, and finally to an alkaline odour. Urine converts the tincture of turnsol into a green colour, from which it is concluded that it contains an acid. No less than thirty different substances have been detected in urine by chemical analysis; viz. a great quantity of salts, acids, ammonia, &c.

Urine is much disposed to spontaneous decomposition. The time when this process commences, and the rapidity of the changes which take place, depend on the quantity of the gelatine and albumen. When the proportion of these substances is considerable, the decomposition is very rapid. This is owing to the great number of substances, and the united force of their attractions overcoming the existing affinities of the different compounds of which fresh urine consists, and especially to the facility with which urea is decomposed. This substance is converted during putrefaction into ammonia, carbonic acid, and acetic acid. Hence the smell of ammonia is always recognized while urine is undergoing these changes. Part of the gelatine is deposited in a flaky form, mixed with mælage. Ammonia combines with phosphoric acid, and the phosphate of lime is precipitated. It combines also with phosphate of magnesia, and forms a triple salt. The other acids, the uric, benzoic, the acetic, and carbonic acids, are all saturated with ammonia.

URN, a kind of vase of a roundish form, but biggest in the middle, like our common pitchers. In ancient times they were much in use among most nations, to preserve the ashes of the dead, to contain liquids used at sacrifices, and to hold the lots upon which the destiny of events depended. At present they are known and valued only as ornaments, or vestiges of antiquity.

URSA MINOR, or **CYNOSURA**, the *Little Bear*, according to the poetry of the skies, represents Arcas, the son of Calisto, who was placed by Jupiter in the heavens under the figure of a bear. This constellation embraces the pole of the world, and is easily distinguished by seven stars in the same form; but in a contrary position to those of the Wain, in the Great Bear.

Boundaries and Contents.—West and north by Draco, east by Camelopardalis, and south by Cassiopeia and Perseus. It extends from the North Pole to the Arctic Circle, and contains twenty-four stars, viz. one of the second magnitude, two of the third, four of the fourth, &c.

URSA MAJOR, the *Great Bear*, is said to be Calisto, an attendant of Diana, the goddess of hunting. Calisto was changed into a bear by Juno, and placed in the heavens by Jupiter. Another account, however, makes Ursa Major to be Arcas, the son of Jupiter and Calisto. Every one knows the story of Lycaon, king of Arcadia, being changed into a wolf, for killing his grandson Arcas, and setting him before Jupiter, to try the divinity of the father of gods and king of men. The ancients, it is said, represented the constellations of the Bears, each under the form of a waggon drawn by a team of horses. Ursa Major is well known to the country people at this day by the title of *Charles's Wain*: in some places it is called the Plough, an agricultural machine, which it certainly resembles.

Boundaries and Contents. North by Camelopardalis and Draco, east by Canes Venatici, south by Leo Minor, and west by Lynx and Camelopardalis.

URSUS, the *Bear*, in Natural History, a genus of mammalia, of the order feræ. There are ten species:—The brown bear, a native of Europe and Asia; the American bear, with a long pointed nose; the Polar bear, completely white and very much larger than the common or brown bear; the glutton, the wolverene, the racoon, and the common badger, found in almost all the temperate regions both of Europe and Asia, living in subterranean habitations, which its feet are admirably adapted for preparing. Its food consists of fruits and roots, frogs and insects; and the resemblance of its teeth to those of beasts of prey, makes it probable that it destroys lambs and larger animals, which it is stated to do: in a domestic state it prefers raw flesh to every other species of food. It will attack beehives, to obtain the honey contained in them. It sleeps much; passes the winter, or the greater part of it, in its barrowed residence, in a state of lethargy and torpor; and in summer produces generally three young ones at a birth. These animals are inoffensive in their manners; reluctant to attack, but well prepared by nature for defence, which they conduct with an alertness, intrepidity, and perseverance, truly admirable. To afford a spectacle of these qualities to the populace of several countries, the badger is often baited with dogs, which from the looseness of the badger's skin, and the coarseness of its hair, are prevented sometimes from penetrating to its flesh with their teeth, and, almost always, from so fastening him by their bite as to preclude his turning in various directions for their annoyance.

USE, is a trust and confidence reposed in another who is tenant of the land, that he shall dispose of the land according to the intention of him to whose use it is granted, and suffer him to take the profits.

USES AND CUSTOMS OF THE SEA, certain general principles, which compose the basis of marine jurisprudence, and regulate the affairs of commerce and navigation.

USURPATION, an injurious appropriation for any given time of the rights or property that justly belongs to another.

USURY, the exacting of a larger interest upon money than by law is allowed. The statute 12 Anne, c. 18, enacts, that no person upon any contract which shall be made, shall take for loan of any money, wares, &c. above the value of 5*l.* for the forbearance of 100*l.* for a year; and all bonds and assurances for the payment of any money to be lent upon usury, whereupon or whereby there shall be reserved or taken above five pounds in the hundred, shall be void; and every person who shall receive by means of any corrupt bargain, loan, exchange, shift, or interest, of any wares or other things, or by any deceitful way, for forbearing, or giving day of payment for one year, for their money or other things, above 5*l.* for 100*l.* for a year, shall forfeit treble the value of the moneys or other things lent.

V.

VACATION, in Law, is the whole time betwixt the end of one term and the beginning of another. This word is also applied to the time from the death of a bishop, or other spiritual person, till the bishopric or dignity is supplied with another.

VACCINATION. Cow-pock inoculation. Inoculation with the vaccine virus, for the purpose of securing against the infection of the small-pox.

VACUUM, in Philosophy, denotes a space empty or devoid of all matter or body.

VACUUM ENGINE, Brown's. Though this engine does not seem to have answered the expectations of its projectors, we very freely admit its description. Its principle is simply this: the formation of a vacuum in a cylinder by the combustion of hydrogen gas;—and that our readers may better comprehend the process by which this is done, and the power thereby obtained, we will first of all quote the inventor's own words.

"Inflammable gas is introduced along a pipe into an open cylinder or vessel, whilst a flame placed on the outside of, but near to the cylinder, is constantly kept burning, and at times comes in contact with and ignites the gas therein: the cylinder is then closed air-tight, and the flame is prevented from communicating with the gas in the cylinder. The gas continues to flow into the cylinder for a short space of time, then it is stopped off; during that time, it acts by its combustion upon the air within the cylinder, and at the same time a part of the rarefied air escapes through one or more valves, and thus a vacuum is effected. The vessel or cylinder is kept cool by water. Several mechanical means may be contrived to bring the above combination into use in effecting the vacuum with inflammable gas, and on the same principle it may be done in one, two, or more cylinders or vessels."—Having a vacuum effected by the above combination and some mechanical contrivance, powers are produced by its application to machinery in several ways. First, water wheels may be turned; secondly, water may be raised; and, thirdly, pistons may be worked.

Description of the Engine as used for Turning a Water-wheel.—The two cylinders *c* and *d* are the vessels in which the vacuum is to be effected; from these descend the pipes *g* *g* and *h* *h* leading into the lower cylinders *x*, *x*, from which the water runs along those pipes to fill the vacuum cylinders alternately. The water thus supplied is discharged through the pipes *B* into the tank or trough *z*, whence it falls upon the overshot water-wheel, and by the rotatory motion thus produced gives power to such machinery as may be connected to it. The water runs from the wheel along a case surrounding the lower half, into a reservoir *v*, from which the lower cylinders *x* *x* are alternately supplied.

In order to produce the vacuum, the necessary quantity of gas is supplied to the cylinders by means of the pipe *k* *k*, to be conveniently attached to a gasometer. The gas also passes along the small pipe *l* *l*, (communicating likewise with the gasometer,) and being lighted at both ends of that pipe, is constantly burning for the purpose of igniting the gas within the cylinders.

The water in the reservoir *v* passing down one of the pipes *w* into one of the lower cylinders *x*, causes the float *y* in that cylinder to rise, and pushing up the rod *e* raises the end *b* of the beam, which of course draws up with it the cap *f*, and thus down the cap *e* of the other cylinder *c*. The gas being admitted along the pipe *k*, the flame from the pipe *l* is now freely communicated to the gas in the cylinder through the orifice by the opening of the sliding valve *s*, which is raised by the arm *r* fixed by the rod *e* by means of the beam.

To produce the unremitting action of each cylinder, some subordinate machinery is put in operation by chains and rods attached to a glass or iron vessel *p*, partly filled with mercury, and, turning upon a pivot, each end receives its movements of elevation and depression from the rise and fall of the projecting arms *q* by the action of the beam above; the mercury being furnished for the purpose of regulating the supply of the gas into the cylinders, and the movement of the slide in the trough *z*. By the action thus communicated, the water from the reservoir flows down the pipe *w* into the vessel *x*, and produces the elevation of the float *y* and the rod *e*, and raises the cap *e* by the ascent of the beam at *b*. The motion thus caused in this part of the machinery, operating upon its duplicate parts on the other side, of course produces by its action a corresponding movement; and the slider in the trough *v*, moved by the action of the mercurial tube *p*, being removed from its position, allows the water to fall into the other pipe *w*, and as it ascends raises the float *y* to descend, and rising into the main cylinder, then lifts again the beam at *b* and its connexions, and forces down the cap *e* on the top of the other cylinder. After the vacuum is effected in the cylinders, the air must be admitted, to allow the water to be discharged and the caps to be raised; this is accomplished by means of a sliding valve in the air pipe *m* *m*, acted upon by chains *t* *t*, attached to the floats in the reservoir,

and as motion is given to them, the valve is made to slide backwards and forwards, so as to allow of the free admission of atmospheric air.

Chains *u u* with suspended weights open the cocks in the pipe *k k*, and produce the alternate flow of the gas, and regulate and modify its supply. In the pipes *g i g* and *h j h* are clacks to prevent the return of the water when the air is admitted into the cylinders. When pistons are worked, the vacuum is effected (in the same manner as abovescribed) under the piston, which is then pressed down by the weight of the atmosphere, and as an engine of that description is worked with two cylinders and pistons, the vacuum being produced in each cylinder alternately, the fall of one piston raises the other, and, being alternately pressed down, the piston rods give motion to the crank and fly-wheel. The air is admitted through large valves in the piston, and through orifices in the cylinders. An engine may be worked with one piston, the vacuum being produced in two cylinders, (as in the water engine,) from which a pipe communicates with a third cylinder in which the piston works, and into which the air is admitted alternately under and over the piston, while the vacuum extends to its opposite sides. By this contrivance a much greater rapidity of motion may be given to the piston, if required.

The method being therefore explained, in which, by the pressure of the air, the vacuum produced (and continued) is applied to useful purposes, Mr. Brown claims to be the inventor of the combination above described for effecting a vacuum, "*however much it may be varied by the mechanical means with which it may be used, and also the inventor of applying a vacuum produced by the combustion of inflammable gas, to raising water, and to the production of motion in machinery by the pressure of the atmosphere.*"

The advantages to be derived from this engine, were detailed in the descriptive outline of the inventor, to be the following:—

1st. "The quantity of gas consumed being very small, the expense of working the engine is moderate. In its application on land, the saving will be extremely great, the cost of the coal gas (deducting the value of the coke) being inconsiderable. The expense of working a marine engine will certainly be greater, as the gas used for that purpose must be extracted from oil, pitch, tar, or some other substance equally portable, yet even in this case it will not equal the cost of the fuel required to propel a steam-boat; and, as a few butts of oil will be sufficient for a long voyage, vessels of the largest tonnage may be propelled to the most distant parts of the world.

2d. "The engine is light and portable in its construction, the average weight being less than *one-fifth* the weight of a *steam-engine (and boiler)* of the same power; it also occupies a much smaller space, and does not require the erection of so strong a building, nor of a lofty chimney. In vessels, the saving of tonnage will be highly advantageous, both in the smaller comparative weight and size of the engine, and in the very reduced space required for fuel.

3d. "This engine is entirely free from danger. *No boiler being used*, explosion cannot take place, and as the quantity of gas consumed is so small, and the only pressure that of the atmosphere, it is impossible that the cylinder can burst, or the accidents incidental to steam-boats occur."

The power of the engine being derived from the atmospheric pressure of ten pounds and upwards to the square inch may be increased with the dimensions of the cylinders to any extent, and always ascertained by the index of the mercurial gauge; the power of the engine is best explained, by adverting to the fact of the mercury in the gauge being raised to the height of 24 inches and upwards. We saw it standing at 26 inches, though the inventor will not authorize any one to rate it higher than 22 inches, that being amply sufficient, as affording an available power superior to that of the condensing steam engine, there being no friction in an engine for raising water, and not more than one pound per square inch in a piston engine of any size. The number of strokes per minute which this engine made was twenty-nine, but a trifling alteration in the mechanism will increase the number to thirty-five or perhaps forty; in fact, the vacuum is so instantaneously formed, that any number of strokes which could be wished may be made. When pistons are worked in a separate cylinder, two or three strokes of the piston may

be made with each stroke of the vacuum cylinder, i. e. each time the vacuum is effected.

VAGABOND, a person who wanders about, having no certain dwelling; such are sturdy beggars mentioned in divers statutes, on whom punishment may be inflicted.

VAGRANTS, are those who threaten to run away and leave their wives and children to the parish. All persons returning to a parish whence they have been legally removed, without a certificate from the parish to which they belong. All who, not having wherewith to maintain themselves, refuse to work. All who beg alms from door to door, or in the streets and highways. Likewise those who, not using proper means to get employment, or, possessing ability to work, refuse to do it; or spend money in ale-houses, or in any improper manner; and by not applying a proper proportion of their earnings towards the maintenance of their families, suffer them to become chargeable to the parish.

VALVE, in Hydraulics and Pneumatics, is a kind of lid or cover to a tube, vessel, or orifice, contrived to open one way, but which, the more forcibly it is pressed the other way, the closer it shuts the aperture, like the clapper of a bellows.

VALVE, in Anatomy, a thin membrane applied on several cavities and vessels of the body, to afford a passage to certain humours going one way, and prevent their reflux towards the place whence they came.

VAN, or **VAUN**, in Mining, is the washing on a shovel a small quantity of tin stuff, or ore, that has been pulverized, so that the waste being washed away, the quality of a large heap may be estimated from the produce of pure ore remaining in the van.

VAN, the foremost division of a naval armament, or that part which leads the way to battle, or advances first in the order of sailing. See the articles **CENTRE**, **FLEET**, **REAR**, &c.

VANE, a piece of bunting sewed upon a wooden frame called the stock, which turns upon a spindle at the mast head: its use is to shew the direction of the wind.

Distinguishing VANE, serves by its situation to denote what squadron a ship belongs to, and by its colour, or combination of colours, to point out the particular ship which bears it.

Dog VANE, a small light vane formed of thin slips of cork, stuck round with feathers, and strung upon a piece of twine. It is usually fastened to the top of a half-pike, and placed on the weather side of the quarter deck, in order to shew the helmsman the direction of the wind, particularly in a dark night, or when the wind is weak.

VANES, in Mathematical or Philosophical Instruments, are sights made to slide and move upon cross-staves, fore-staves, quadrants, &c.

VANGS, a sort of traces to steady the mizzen peak, extending from the peak downwards to the aftmost part of the ship's quarters, where they are hooked and drawn tight, so as to be slackened when the wind is fair, and drawn in to windward when it becomes unfavourable to the ship's course.

VAPOUR, a thin vesicle of water, or other humid matter filled or inflated with air, which being rarefied, ascends to a certain elevation in the atmosphere, and is there suspended till it returns in rain or snow. An assemblage of such vapours constitutes what is called a cloud.

VAPOUR Bath. See **BATH**.

VARIATION, is a term applied to the deviation of the magnetic needle, or compass, from the true north point, towards either east or west, called also Declination. The variation of the needle is properly defined the angle which a magnetic needle suspended at liberty makes with the meridian line on an horizontal plane; or an arch of the horizon, comprehended between the true and magnetical meridian. In the sea language it is usually called north-easting or north-westing. All magnetic bodies range themselves in some sort to the meridian; but it is rarely that they fall in precisely with it; in one place they decline from the north to the east, and from the south to the west; and in another place, on the contrary, from the north to the west, and from the south to the east, and that, too, differently at different times. Various are the hypotheses framed to account for this extraordinary phenomenon; we shall only mention some of the later and more probable; only premising, that Mr. Robert Norman, the inventor of the dipping needles, disputes against

Cortez's notion, that a variation was caused by a point in the heavens, contending that it should be sought for in the earth, and proposes how to discover its place. The first is that of Gilbert, which is followed by Cabeus, &c. This notion is, that it is the earth or land that draws the needle out of its meridian direction; and hence they agree that the needle varied more or less, as it was more or less distant from any great continent; consequently, that if it were placed in the middle of an ocean equally distant from equal tracts of land on each side, west and westward, it would not decline either to the one or the other, but point justly north and south. Thus they say, in the Azores, which are equally distant from Africa on the east and America on the west, no variation is found; but as from the Azores you sail towards Africa, the needle begins to decline from the north to the east, and that still more till you reach the shore. If you still proceed eastward, the declination gradually diminishes again, by reason of the land left behind on the west, which continues to draw the needle. The same holds till you arrive at a place where there are equal tracts of land on each side, and there again there is no variation. The observations of our mariners in their East India voyages seem to confirm this system. As they proceed towards the Cape of Good Hope, the variation is still eastward; at length arriving at the Cape de los Aguillas, q. d. of the needles, the meridian line then dividing Africa into two equal parts, there is no variation at all, but as they proceed farther, and leave the African coast on the west, the variation becomes westward. But the misfortune is, the law does not hold universally; in effect, a great number of observations of the variations, in various parts, made and collected by Dr. Halley, overturn the whole theory. Others, therefore, have recourse to the frame and compasses of the earth, considered as interwoven with rocks and shelves, which being generally found to run towards the poles, the needle comes to have a general tendency that way, but which seldom going perfectly in the direction of the meridian, the needle, of consequence, has commonly a variation. Others hold various parts of the earth to have various degrees of the magnetic virtue, as some are more intermixed than others with heterogeneous matters, which prevent the free action or effect thereof. Others ascribe all to magnetic rocks and iron mines, which affording more of the magnetic than other parts, draw the needle more. Lastly, others imagine earthquakes or high tides to have disturbed and dislocated several considerable parts of the earth, and so changed the magnetic axis of the globe, which originally was the same with the axis of the globe itself.

Dr. Hooke communicated to the Royal Society, in 1674, a theory of the variation, the substance of which is, that the magnet has its peculiar pole, distant ten degrees from the pole of the earth, about which it moves, so as to make a revolution in 370 years; whence the variation, he adds, has altered of late about 10 or 12 minutes every year, and will probably so continue to do for some time, till it begins to become slower and slower, and will at length be stationary and retrograde, and in all probability may return.

Dr. Halley, in his day, gave another system, the result of a great number of observations, and even of a great number of voyages made at the public charge on this account. The light that excellent author imparted to this obscure portion of natural history is very great, and the consequences thereof in navigation, &c. are very considerable.

From these observations the learned author infers, 1. Throughout all Europe the variation at this time is west, and is more in the eastern parts thereof than in the western, increasing that way. 2. That on the coast of America the variation is westerly, increasing all the way as you go northerly along the coast, so as to be about 20° at Newfoundland, nearly 30° in Hudson's Straits, and not less than 57° in Baffin's Bay; and that as you sail eastward from this coast, the variation constantly diminishes. Hence he argues that somewhere between Europe and the north part of America there must be an easterly variation, or at least no variation. 3. That on the coast of Brazil there is an east variation increasing as you go to the southward, so as to be 12° at Cape Frio, and 20° and half over against Rio Plata, and thence sailing south-westerly to the Straits of Magellan, it decreases to 17° , and at the west entrance is about 14° . 4. That eastward of Brazil this easterly variation decreases, so as to be very

little at St. Helena and Ascension, and to be quite gone, and the compass point true about 11° longitude west from the Cape of Good Hope. 5. That to the eastward of the aforesaid places, a westward variation begins, and governs in all the Indian Sea, rising to 16° under the equator, about the meridian of the northern part of Madagascar, and $27\frac{1}{2}^{\circ}$ in 39° south latitude near the same meridian; easterly from thence the west variation decreases so as to be not much above 8° at Cape Camorin, and about 3° upon the coast of Java, and about the Molucca islands to be quite gone, as also a little to the westward of Van Diemen's Land. 6. That to the eastward of the Moluccas and Van Diemen's Land in south latitude, there is another easterly variation, which seems not so great as the former, nor of so large extent; because, at the Isle of Rotterdam it is more sensibly felt than upon the east coast of New Guinea; and, at the rate it decreases, it may well be supposed that about 20° farther eastward, and 105° east longitude from London, in the latitude of 20° south, a westerly variation begins. 7. That the variation taken at Baldivia, and at the west entrance of the Straits of Magellan, shews that the east variation noted in the third observation is decreasing space, and that it cannot extend many leagues from the South Sea into the coast of Peru and Chili, leaving room for a small westerly variation in that tract of the unknown world that lies in the midway between Chili and New Zealand, and between Hounds Island and Peru. 8. That in sailing north-west from St. Helena, by Ascension, as far as the equator, the variation continues very small east, as it were constantly the same; so that in this part of the world, the course, wherein there is no variation, is evidently no meridian, but rather north-west. 9. That the entrance of Hudson's Straits, and the mouth of Rio Plata, being nearly under the same meridian at the one place, the needle varies $29\frac{1}{2}^{\circ}$ west; at the other $20\frac{1}{2}^{\circ}$ east. This, he says, demonstrates the impossibility of reconciling these variations by the theory of Bosd, which is by two magnetical poles, and an axis inclined to the axis of the earth: whence it would follow, that under the same meridian the variation should in all places be the same. From these circumstances the learned author takes occasion to assert, "that the whole globe of the earth is one great magnet, having four magnetical poles or points of attraction; near each pole of the equator two; and that in those parts of the world which lie nearly adjacent to any one of these magnetical poles, the needle is governed thereby, the nearest pole being always predominant over the more remote." The pole which at present is nearest to us, he conjectures to lie in or near the meridian of the Land's End of England, and not above 7° from the arctic pole; by this pole the variations in all Europe and Tartary, and the North Sea, are principally governed, though still with some regard to the other northern pole, whose situation is in the meridian, passing about the middle of California, and about 15° from the north pole of the world, to which the middle has chiefly respect in all North America, and in the two oceans on either side thereof, from the Azores westward, to Japan, and farther. The two southern poles, he imagines, are rather farther distant from the south pole of the world, the one about 16° therefrom in a meridian, 20° to the westward of Magellan's Straits, or 90° west from London; this commands the needle in all South America, in the Pacific ocean, and the greatest part of the Ethiopic ocean. The other seems to have the greatest power and the largest dominion of all, as it is the most remote from the pole of the world, being little less than 20° distant therefrom in the meridian which passes through New Holland and the island of Celebes, about 120° east from London; this pole is predominant in the south part of Africa, in Arabia and the Red sea, in Persia, India, and its islands, and all over the Indian Sea, from the Cape of Good Hope eastwards to the middle of the Great South Sea, that divides Asia from America. Such seems to be the present disposition of the magnetical virtue throughout the whole globe of the earth. It remains to shew how this hypothesis accounts for all the variations that have been observed of late, and how those variations answer to the several remarks which Dr. Halley made.

It is plain, as our European north pole is in the meridian of the Land's End of England, all places more easterly than that will have it on the west side of the meridian; and consequently the needle, respecting it with its northern point, will have a west-

erly variation, which will still be greater as you go to the eastward, till you come to some meridian of Russia, where it will be the greatest, and from thence will decrease again. Accordingly, in fact we find that at Brest the variation was but $1\frac{1}{2}^{\circ}$, at London $4\frac{1}{2}^{\circ}$ (in 1683) and at Dantzic 7° west.

Again, to the westward of the meridian of Land's End, the needle ought to have an easterly variation, were it not that by approaching the American north pole (which lies on the west side of the meridian, and seems to be of greater force than this other) the needle is drawn thereby westward, so as to counterbalance the direction given by the European pole, and to make a small west variation in the meridian of the Land's End itself. Yet, about the Isle of Terceira, it is supposed our nearest pole may so far prevail as to give the needle a little turn to the east, though but for a very little space, the counterbalance of those two poles admitting no considerable variation in all the eastern parts of the Atlantic ocean, nor upon the west coasts of England and Ireland, France, Spain, and Barbary. But to the westward of the Azores, the power of the American pole overcoming that of the European, the needle has chiefly respect thereto, and turns still more and more towards it as we approach it. Whence it comes to pass, that on the coast of Virginia, New England, Newfoundland, and in Hudson's Straits, the variation is westward, that is, it decreases as you go from thence towards Europe, so that it is less in Virginia and New England than in Newfoundland and Hudson's Straits.

2. This westerly variation again decreases as you pass over North America, and about the meridian of the middle of California, the needle again points due north; and from thence westward to Yedzo and Japan, it is supposed the variation is easterly, and half sea over not less than 15° ; and that this east variation extends over Japan, Yedzo, Tartary, and part of China, till it meets with the westerly, which is governed by the European north pole, and which is the greatest somewhere in Russia.

3. Towards the south pole the effect is much the same, only that here the south point of the needle is attracted. Whence it will follow, that the variation on the coast of Brazil, at the river of Plata, and so on to the Straits of Magellan, should be easterly, if we suppose a magnetical pole situate about 20° more westerly than the Straits of Magellan. And this easterly variation extends eastward over the greatest part of the Ethiopic sea, till it be counterpoised by the virtue of the other southern pole, as it is about midway between the Cape of Good Hope and the Isles of Tristan d'Alcunha.

4. From thence eastward, the Asiatic south pole becoming prevalent, and the south point of the needle being attracted thereby, there arises a west variation very great in quantity and extent, because of the great distance of this magnetical pole from the pole of the world. Hence it is, that in all the Indian seas, as far as New Holland, and farther, there is constantly a west variation, and that under the equator itself it rises to no less than 11° where it is most. And that about the meridian of the island of Celebes, being likewise that of this pole, this westerly variation ceases, and an easterly one begins, which reaches to the middle of the South Sea, between New Zealand and Chili, leaving room for a small west variation, governed by the American south pole.

5. From the whole it appears that the direction of the needle in the temperate and frigid zones depends chiefly upon the counterpoise of the forces of two magnetical poles of the same nature; as also why, under the same meridian, the variation should be in one place $29\frac{1}{2}^{\circ}$ west, and in another $20\frac{1}{2}^{\circ}$ east.

6. In the torrid zone, and particularly under the equinoctial, respect must be had to all the four poles, and their position must be well considered, otherwise it will not be easy to determine what the variation shall be, the nearest pole being always strongest; yet not so as not to be counterbalanced sometimes by the united forces of two more remote. Thus in sailing from St. Helena by the isle of Ascension to the equator, on the north-west course, the variation is very little easterly, and in that whole tract is unalterable; because the South American pole, which is considerably the nearest in the aforesaid places, requiring a great easterly variation, is counterpoised by the contrary attraction of the North American and the Asiatic south poles; each whereof singly is, in these parts, weaker than the

American south pole, and upon the north-west course the distance from this latter is very little varied; and as you recede from the Asiatic south pole, the balance is still preserved by an access towards the North American pole. In this case, no notice is taken of the European north pole, its meridian being a little removed from those of these places, and of itself requiring the same variations. And after the same manner may the variations in other places, under and near the equator, be accounted for.

VARIATION of the Variation, is the change for the declination of the needle, observed at different times in the same place. This variation was first discovered by Mr. Henry Gellibrand, by comparing the observations made at different times near the same place by Mr. Burrough, Mr. Gunter, and himself, and the discovery was soon known abroad; for Kircher, in his treatise intitled "Magnes," says, that our countryman, Mr. John Creaves, had informed him of it; and then gives a letter of the famous Mercennus, containing a very distinct account of it. Indeed, in the History of the Royal Academy of Sciences at Paris, it is said by M. de Fontinetti, that the learned Gassendi himself acknowledged that he had before received information of Gellibrand's discoveries. This change is gradual and universal, and not accountable for. According to Dr. Halley, the variation of the variation of the compass is supposed to be owing to the difference of velocity of the motions of the internal and external parts of the globe. Such are the irregularities that experience has shewn us in the variation of the magnetic needle, which appear so considerable, that we cannot think it wholly under the direction of one general and uniform law; but rather conclude, with the learned and judicious Dr. G. Knight, that it is influenced by various and different magnetic attractions, in all probability occasioned by heterogeneous compositions in the great magnet, the earth.

VARNISHING. Varnish is a clear limpid fluid, which hardens without losing its transparency. It is used by painters, gilders, &c. to give a lustre to their works, and to preserve and defend them from the air and moisture. A coat of varnish ought to possess the following properties:

1. It must exclude the action of the air; because wood and metals are varnished to defend them from decay and rust.
2. It must resist water; else the effect of the varnish could not be permanent.
3. It ought not to alter the colours it is intended to preserve. It is necessary, therefore, that every varnish should be easily spread over the surface, without leaving pores or cavities, that it should not crack or scale, and that it should resist water.

Resins are the only bodies that possess these properties; they must therefore form the basis of every varnish. For this purpose they must be dissolved as minutely divided as possible, and combined so that the imperfections of those that might be disposed to scale may be corrected by others. Resins may be dissolved by three agents: 1. by fixed or fat oil; 2. by volatile or essential oil; 3. by spirit of wine. Accordingly we have three kinds of varnish; *fat or oily varnish*, *essential varnish*, and *spirit varnish*. And these agents are of such a nature as either to dry up and become hard, or else to evaporate and fly off, leaving the resin fixed behind.

Varnishes should be carefully kept from dust, and in very clean vessels: they should be laid thin and even with a large flat brush, the strokes being drawn all one way. A warm room does best for varnishing in, cold chills the varnish and prevents it from lying even.

Varnishes are polished with pumice-stone and tripoli. The pumice-stone reduced to a fine powder is put upon a piece of serge moistened with water; and with this the varnished substance is rubbed equally and lightly. The tripoli, also reduced to a fine powder, is put upon a clean woollen cloth moistened with olive oil, with which the polishing is performed. The varnish is then wiped with soft linen, and when dry, cleaned with starch, or Spanish white, and rubbed with the palm of the hand, or a linen cloth.

Fat Oil Varnish.—Fixed or fat oil does not evaporate, nor become dry of itself. And therefore to make it dry it is boiled with metallic oxides. Litharge is generally used for this purpose. Oil so prepared is called *drying-oil*. But to accelerate the drying of oil-varnish, we add oil of turpentine.

Gum-copal and amber are the substances chiefly employed in oil varnishes; the copal is white, and used for varnishing light, the amber for dark colours. Before mixing them with the oil, it is best to dissolve them; because they are then in less danger of being scorched, the varnish is also more beautiful. They should be melted in an iron pot; they are in a proper state for receiving the oil when they offer no resistance to the iron spatula, and run off from it drop by drop.

To make oil varnish, pour, by little and little, six or eight ounces of drying oil among sixteen ounces of melted copal or amber, constantly stirring the ingredients with the spatula. When the oil is well mixed with the copal or amber, take it off the fire; and when nearly cool, put in sixteen ounces of the essence of Venice turpentine. The varnish should be passed through a linen cloth. Oil varnishes become thick by keeping; when they are to be used, it is only necessary to pour in a little Venice turpentine, and put them a short time on the fire. Less turpentine is necessary in summer than winter; too much oil hinders the varnish from drying; when too little is used, it cracks and does not spread properly.

To make the best White Hard Varnish.—Rectified spirits of wine, 2 galls.; gum anise, 4 oz.; gum mastich, 1 lb.; gum sandarach, 5 lbs. Put these into a clean can or bottle to dissolve, in a warm place, frequently shaking it; when the gum is dissolved, strain it through a lawn sieve, and it is then fit to use.

Black Varnish for Coaches and Iron Work.—This varnish is composed of asphaltum, resin, and amber, melted separately, and afterwards mixed, the oil is then added, and afterwards the turpentine, as directed above. The proportions are, twelve ounces of amber, two of resin, two of asphaltum, six of oil, and twelve of turpentine.

A Varnish for rendering Silk Impenetrable to Water and Air.—To render linseed-oil drying, boil it with two ounces of sugar of lead, and three ounces of litharge, for every pint of oil, till the oil has dissolved them; then put a pound of bird-lime, and half a pint of the drying oil, into an iron or copper pot holding about a gallon, and let it boil gently over a slow charcoal fire, till the birdlime ceases to crackle; then pour upon it two pints and a half of drying oil, and boil it for about an hour longer, stirring it often with an iron or wooden spatula. As in boiling the varnish swells much, the pot should be removed from the fire, and replaced when the varnish subsides. While it is boiling it should be occasionally examined, to determine whether it has boiled enough. For this purpose take some of it upon the blade of a large knife, and after rubbing the blade of another knife upon it, separate the knives; and when on their separation the varnish forms threads between the two knives, it has boiled enough, and should be removed from the fire. When it is almost cold, add about an equal quantity of spirits of turpentine; mix both well together, and let the mass rest till the next day; then having warmed it a little, strain and bottle it. If it is too thick, add spirits of turpentine. This varnish should be laid upon the stuff when perfectly dry, in a lukewarm state; a thin coat of it upon one side, and about twelve hours after two other coats should be laid on, one on each side; and in twenty-four hours the silk may be used.

Blanchard's Air Balloon Varnish.—Dissolve elastic gum (Indian-rubber,) cut small, in five times its weight of spirits of turpentine, by keeping them some days together; then boil one ounce of this solution in eight ounces of drying linseed-oil for a few minutes, and strain it: use it warm.

Essential Oil Varnish.—The essential varnishes consist of a solution of resin in oil of turpentine. This varnish being applied, the turpentine evaporates, leaving the resin behind. They are commonly used for pictures.

To dissolve Gum Copal in Oil of Turpentine.—The quantity to be dissolved should be put into a glass vessel capable of containing at least four times that quantity, and it should be high in proportion to its breadth. Reduce two ounces of copal to small pieces, put them into a proper vessel. Mix a pint of oil of turpentine with one-eighth its quantity of spirit of sal ammoniac; shake them well together; put them to the copal, cork the glass, and tie it over with a string of wire, making a small hole through the cork. Set the glass in a sand heat so regulated as to make the contents boil as quickly as possible, but so gently, that the air-bubbles may be counted as they rise

from the bottom. The same heat must be kept up till the solution is complete. It requires accurate attention to succeed in this operation. After the spirits are mixed they should be kept to the copal, and the necessary degree of heat given as soon as possible. It should likewise be kept up with the utmost regularity. If the heat abates, or the spirits boil quicker than is necessary, the solution will immediately stop, and with the same materials will afterwards be in vain to proceed: but if properly managed, the sal ammoniac spirit will gradually descend from the mixture, and attack the copal, which will melt and dissolve, except a very small quantity that will remain undissolved. The vessel should not be opened till some time after it has cooled, as it has happened that on uncovering the vessel when it was not warm enough to affect the hand, that the contents have been blown against the ceiling. The spirit of turpentine should be of the best quality, had from Apothecaries' Hall. This varnish, though a rich deep colour in the bottle, gives no colour to the pictures it is laid on. If left in the damp it remains tacky a long time; but in a warm room, or the sun, it dries as other turpentine varnishes.

Spirit Varnishes.—When resins are dissolved in alcohol (spirits of wine,) the varnish dries speedily, but cracks. This fault is corrected by adding a small quantity of oil of turpentine, which renders it brighter and less brittle when dry.

To dissolve Gum Copal in Spirits of Wine.—Dissolve half an ounce of camphor in a pint of alcohol, put it into a circulating glass, add four ounces of copal in small pieces; set it in a sand heat, so regulated that the air-bubbles may be counted as they rise from the bottom; and continue the same heat till the solution is completed. Camphor acts more powerfully upon copal than any other substance. If copal finely powdered be rubbed with a small quantity of dry camphor in the mortar, the whole becomes in a few minutes a tough coherent mass. The most economical method is to set the vessel which contains the solution by for a few days; and when perfectly settled, pour off the clear varnish, and leave the residuum for a future operation. This is a very bright solution of copal, and an excellent varnish for pictures, besides being an improvement in fine japan works, as the stoves used in drying those articles may drive off the camphor entirely, and leave the copal pure and colourless upon the work. Copal dissolves in spirits of turpentine, by the addition of camphor, with the same facility, but not in the same quantity, as in alcohol.

A Varnish for Wainscot, Case Chairs, &c.—Dissolve in a quart of spirits of wine, eight ounces of gum-sandarach, two ounces of seed-lac, and four ounces of resin; then add six ounces of Venice-turpentine. If the varnish is to produce a red colour, more of the lac and less of the sandarach should be used, and a little dragon's blood should be added. This varnish is very strong.

A Varnish for Toilet Boxes, Cases, Fans, &c.—Dissolve two ounces of gum-mastich, and eight ounces of gum sandarach, in a quart of alcohol; then add four ounces of Venice turpentine.

A Varnish for Violins, and other Musical Instruments.—Put four ounces of gum sandarach, two ounces of lac, one ounce of gum-clemi, into a quart of alcohol, and hang them over a slow fire till they are dissolved; then add two ounces of turpentine.

Varnish for employing Vermilion for Painting Equipages.—In a quart of alcohol dissolve six ounces of gum sandarach, three ounces of gum lac, and four ounces of resin; add six ounces of the cheapest kind of turpentine afterwards; mix it with a proper quantity of vermilion when used.

Seed Lac Varnish.—Put one quart of spirits of wine in a wide-mouthed bottle, add eight ounces of seed-lac, clear and free from dirt; let it stand two days or longer in a warm place, shaking it often. Strain it through a flannel into another bottle, and it will be fit for use.

Shell-Lac Varnish.—Take one quart of spirits of wine, eight ounces of thin transparent shell lac, which if melted in the flame of a candle, will draw out in fine long hair; mix and shake them together, and let them stand in a warm place for two days, and it will be ready for use. This varnish is softer than that made from seed-lac, and not so useful, but may be mixed with it for varnishing wood, &c.

White Varnish for Clock Faces, &c.—Take of highly rectified spirits of wine one pint, which divide into four parts; then mix

part with half an ounce of gum-mastich in a phial, one part of spirits, and half an ounce of gum-sandarach in another phial, one part of spirits, and half an ounce of the whitest parts of gum-benjamin. Then mix and temper them to your mind, and it may not be amiss to add a little bit of white resin, ochre, Venice turpentine, in the mastich bottle, to give a gloss. If your varnish be strong and thick, add spirits of wine only; if hard, some dissolved mastich; if soft, some sandarach of benjamin. When you have brought it to a proper temper, warm the silvered plate before the fire (if a clock face, taking care not to melt the wax,) and with a flat camel's hair pencil stroke it all over until no white streaks appear, and this will preserve silvering many years.

VASE. See URN.

VAULT, in Architecture, an arched roof, so contrived that the stones which form it sustain each other. Vaults are, on many occasions, to be preferred to soffits or ceilings, as they give a greater height and elevation, and are besides more firm and durable.

VAULTING, in the article GYMNASTICS, page 430, we referred to the word *Vaulting* for this branch of those physical exercises.—By means of a very simple instrument a great number of our most useful exercises in vaulting may be executed. The figures 6 and 7 of the plate *Gymnastic Exercises* can be employed to perform all the exploits of the pole. The vaulting beam *i k*, fixed between the two standards *c d*, renders it fit for performing on it all the elementary exercises of vaulting. A board with the edges rounded, placed in the same direction, between the standards, may serve to accustom young people to walk on narrow objects, fixed at several elevations. The same board, as in *c f*, fig. 7, fixed like the pole, can be employed with advantage to accustom them to raise the body as high as possible, supported only by the last phalanges of the fingers. A rope with a small sack filled with sand at each end, two little iron spikes to support and make it easily moveable upwards and downwards, presents the most useful and least dangerous instrument to exercise boys in every kind of jumping.—Those who have but a small room, in order to exercise the arms, may fix in one of the corners, at six or eight feet from the ground, and from one wall to the other, a strong pole, eight feet long and three inches thick, on which the following exercises can be performed, which are the most useful in increasing prodigiously the strength of the upper limbs.

Hanging by both Arms, Figure 7, No. 1 and 4.—Here the two arms ought to support for several minutes the whole weight of the body, by which they will be stretched while all the other parts of the body hang loose. This cannot be done by children of a weak constitution, for it is necessary that they should raise their knees, and for safety, some one should remain near them to prevent their falling. In descending, let both hands go at once, and light on both points of the feet, the knees bent as a bird alights, and the upper part of the body inclined forwards.

Hanging alternately on one Hand and Foot, No. 3.

Hanging on both Hands, the Nails turned inside, No. 1 and 4.

Hanging on both Arms outside, like No. 5.—In this position communicate to the body a swinging movement backwards and forwards; and after balancing a moment jump backwards, let go both hands at once, and come down on the points of the feet.

Sliding Sideways.—This consists in bringing the body from one end of the pole to the other, by moving upon it one hand after another in an oblique direction. Children of a weak constitution ought, during this action, to be a little sustained in the loins; and it is necessary to oblige them, during the exercise, to raise their knees as high as possible, and to move them in concert with the arms.

Hand over Hand.—Fixed on the pole, as is represented in No. 4, move forwards and backwards, passing one hand over the other, carefully observing in the beginning to fix the hands not too far from one another.

Advancing by Jumps.—Or moving both hands at once from one place to another; at first forwards from one end of the pole to the other, and after that the same exercise in a contrary direction.

Hanging on the Elbows backwards, and Balancing.—In this movement it is necessary in jumping down, to let go both arms at once, in the very moment the feet are moving backwards.

Changing both Hands at once.—Is to take several times alternately the position as figs. 1 and 4, without coming on the ground.

Right about Face.—Is one of the most difficult of these exercises; it ought therefore to be made very gently. Fixed as in No. 4, after having raised the body as high as possible, let go both hands at once, bring them on the pole in an opposite direction, as you were before. By this movement the body has made right about face.

To turn over, No. 6.—The hands fixed as before; after a strong movement of impulse, bring your legs upwards and lie upon the pole with the girdle, or if you can well support yourself without loosening your hands, turn round the pole and come on your feet.

This is the genuine *Salto mortale*, fixed by the hands or feet over-head. The same exercise can be done having the hands fixed as in number 5 and 6.

To Slide down.—Sitting in the middle of the pole, both hands fixed on one side of the body, to the right for example. The right hand near the right hip, the nail turned to the face, the hands strongly fixed. From this position slide gently forward, and you will hang on both arms; after having turned over, come up again, sit upon the poles as before, and repeat the exercise several times on both sides without coming on the ground.

Leaping.—In general, of all the leaps, the most sure, useful, and agreeable, is the vaulting in a straight direction, and is that which we can employ on a great many occasions. A man who has acquired the facility to perform it well, may easily jump over objects of his own height, and even more, without any danger whatever.

The first exercises which we ought to make in order to supply all the joints, are in general, the most useful and profitable for every kind of jump.

In raising the knees and supporting the body in equilibrium upon the hands, bring the legs several times up and down without touching the beam with any other part of the body. After having practised this exercise a little time, it will be very easy for any body to stand on the beam, since, to rise up from the first position, there is nothing else to be done than to bend the body a little forwards, bring the heel of the right foot before the ankle of the left, and rise up gently. To come down, the knees bent gradually, the hands come on the beam, and as soon as the weight of the body lies upon them, the feet leave their place, and take their first position.

In Walking forwards.—From the first position, bring one hand forwards by sliding it close to the other, till the last articulation of the thumb of the moving hand comes in the direction of the nail of the other, and then continue on the same way till you can perform it with ease, always observing an equal distance in your steps.

In Walking backwards.—The same exercise, moving backwards, though much more difficult than the preceding, may be executed very soon by those who have well observed the rules of the former. Here, while the hands are moving backward, the upper part of the body is kept forward.

Jumping between.—To perform this exercise easily, place the beam the height of the middle of the thigh; put both hands upon it, and by giving a little impulse upwards, bring both feet at once, close between the hands, without moving them from their place, and continue the same exercise until it can be done easily. Having acquired some dexterity in this, try, by jumping in the same manner, to pass one leg through the hands, and return without touching the beam with it. In passing the leg through, the body is kept backward, and in bringing it back, it is bent forward. Do the same with both legs together, observing the same rules.

Jumping through.—Here it is necessary to have some one to stand by to assist; and in the beginning this exercise ought to be made with very great precision. The preceding exercises having been well made, it will be very easy to jump through the hands, because there is nothing else to be observed than to push the body forwards and let both hands go at once after the legs are passed through the hands in a straight direction.

Jumping over.—This manner of jumping is very agreeable and sure, because in the action we have always the power to direct the body with the greatest ease in whatever direction we please. Placed before the beam, which is at first as high as

the hips, lay both hands upon it, then bending down raise the body at once with all your strength over the beam. In jumping to the right, the left foot passes between both hands, the right hand lets go, and the left guides the body in its fall. In jumping to the left, the right foot passes between both hands.

In whatever direction this jump be made, you ought not only to be master of your equilibrium, but must also be able to point out, before jumping, the place where you intend to fall, observing at the same time to come on the ground on both feet, the knees projected forward, the hands ready to neutralize the fall if necessary.

Parallel Bars.—The instruments employed to perform the exercises here described, are two pieces of wood from six to eight feet in length, and four inches square, the edges rounded. For grown men they are fixed at two feet distance from one another, and for children, at eighteen inches, supported by two round standards firmly fixed in the ground, and from three to four feet high, according to the stature of the boys.

It is necessary that during the exercises the instructor should always remain near the boy who is exercising, on purpose to assist him if he should make a false movement.

Balancing, No. 1.—Being placed in the middle of the bars, and between both, put your hands right and left on each bar on the same line. After a little jump upwards, preserve your equilibrium on both wrists, the legs close, and in that position which we call the first; then communicate to your body a gentle movement of balancing from behind, forwards, and continue so several times. In the beginning, it is necessary to observe, not to bring the feet too high to make this exercise with precision, and without making any movement with the arms; the body moving as it were upon a pivot.

To bring both legs over.—From the first position, after a little movement of balancing, bring both legs close and at once, over one of the bars forwards without touching it, or moving your hands from their place. The same ought to be made backwards right and left.

Crossing.—After having made several times the preceding exercises, and got some readiness in them, you can try this: having both legs on the right (where the right hand lies) bring them in at once upon the left backwards, after that between, then over the left forwards, from thence over the right backwards, and continue on in the same manner from right backwards to the left forwards, between, over the right forwards, and over the left backwards.

Doubling.—Having both legs over the left bar, forwards, bring them close, and without falling between, or touching the bars, place them over the right forwards, then over the left, and continue so for some time. The same exercise, behind, is much more difficult, but by practice you may acquire readiness in this as well as in the former. Observe to bring the body forwards at the same time that you bring your legs over both bars.

To Jump out.—After having communicated to the body a movement of balance, the moment in which the legs are raised over the bars, jump backwards over the right, without touching it with the feet or waist; then perform the same jump forwards. By the vaulting jump you may easily come between the bars, and also bring your body over both, without touching them otherwise than with your hands.

To rise up, fixed by the legs.—Sitting upon one of the bars, place the upper part of your feet under the lower part of the other bar, and slide backwards upon your thighs till you come to hang in the joints of your knees. In this position the points of your feet, and the upper part of your calves, are the only part of the body which touch the bars. Also fixed, bring the upper part of your body gently down and backwards, laying your hands crossed upon the chest, and holding the head upright, then raise up your trunk several times. At the beginning make this exercise no more than five or six times without rest. When once accustomed to it, you may perform it forty or fifty times without any ill consequence attending it.

Moving upon the Hands forwards and backwards.—To perform this exercise either forwards or backwards, it is necessary to make but little movement in sliding your hands upon the bar, holding the body upright. No. 1.

Advancing by Leaps.—From the first position, after having

communicated to the body an impulsion forwards, lift both hands at once, and bring them forwards upon the bars, keeping them always in the same line. To execute this exercise backwards, it is necessary to keep the upper part of the body as much forwards as possible.

To rise, and sink down, No. 2.—In equilibrium in the middle of the bars, place the legs backwards, the heels close to the upper part of the thigh. From this position come gently down till the elbows rest upon the bars; then rise up gently without any impulse, or touching the ground with your feet. This ought to be repeated several times without resting. As soon as you can perform this easily, in rising up try to bring the knees as high as possible in the direction of the face.

To touch the ground with the knees.—In this exercise the legs are folded backwards, and the same movements are made as in the former, by going gently down between the bars, till the knees touch the ground, moving up and down several times.

VECTOR, in Astronomy, a line supposed to be drawn from any planet moving round a centre, or the focus of an ellipse, to that centre or focus.

TO VEER AND HAUL, to pull a rope tight by drawing it in and slackening it alternately till the body to which it is applied acquires an additional motion like the increased vibrations of a pendulum, so that the rope is strained to a greater tension with more facility and despatch; this method is particularly used in hauling the bowlines. The wind is said to veer and haul when it alters its direction, and becomes more or less fair. The it is said to veer aft, and haul forward.

VEERING is the operation by which a ship, in changing her course from one board to the other, turns her stern to windward. See the article **WARR**.

VEIN, among Miners, is that space which is bounded with woughs, and contains ore, spar, canok, clay, chert, croil, brecheu, pitcher-chert, cur, which the philosophers call the mother of metals, and sometimes soil of all colours. When it bears ore, it is called a quick vein; when no ore, a dead vein.

VELVET, a rich kind of stuff, all silk, covered on the outside with a close, short, fine, soft shag, the other side being a very strong close tissue.

VENEERING, VANEERING, or Finccring, a kind of marquetry or inlaying, whereby several thin slices or leaves of the woods, of different kinds, are applied and fastened on a ground of some common wood. There are two kinds of inlaying, the one which is the most common and more ordinary, goes as far as the making of compartments of different woods; the other requires much more art, in representing flowers, birds, and similar figures. The first kind is properly called veneering, the latter is more properly called marquetry. The wood used in veneering is first sawed out into slices or leaves about a line in thickness; i. e. the twelfth part of an inch. In order to saw them, the blocks or planks are placed upright in a kind of sawing press. These slices are afterwards cut into narrow slips, and fashioned divers ways, according to the design proposed; then the joints having been exactly and nicely adjusted, and the pieces brought down to their proper thickness with several planes for the purpose, they are glued down on a ground or block with good strong English glue. The pieces being thus jointed and glued, the work, if small, is put in a press; if large, it is laid on a bench, covered with a board, and pressed down with poles or pieces of wood, one end of which reaches to the ceiling of the room, and the other bars on the board. When the glue is thoroughly dry, it is taken out of the press and finished, first with little planes, then with scrapers, some of which resemble rasps, which take off the dents, &c. left by the planes. After it has been sufficiently scraped, they polish it with the skin of a dog-fish, wax, and a brush, or polisher of shave-grass; which is the last operation.

VENOM. See **POISON**.

VENTILATION, comprises the various modes by which impure air is removed or renovated by introducing a current of pure atmospheric air.

VENTILATOR, a machine by which the noxious air of any close place, as a hospital, gaol, ship, chamber, &c. may be changed for fresh air.

VENTRILOQUISM, an art by which certain persons can so modify their voice as to make it appear to the audience to

proceed from any distance, and in any direction. It appears that ventriloquism is the art of mimicry, an imitation applied to sounds of every description, and attended with circumstances which produce an entertaining deception, and lead the hearers to imagine that the voice proceeds from different situations. When distant, and consequently lower voices are to be imitated, the articulation may be given with sufficient distinctness, without moving the lips, or altering the countenance. It was by a supposed supernatural voice of this kind, from a ventriloquist, that the famous musical small-coal man, Thomas Britton, received a warning of his death, which so greatly affected him that he did not survive the affright.

VENUE, the neighbourhood from whence juries are to be summoned for trial of causes. In local actions, as of trespass and ejectment, the venue is to be from the neighbourhood of the place where the lands in question lie; and in all real actions the venue must be laid in the county where the property is for which the action is brought.

VENUS, in Astronomy, one of the inferior planets, revolving round the sun in an orbit between that of Mercury and the Earth.

VEPRECULÆ, diminutive from *vepres*, "a briar or bramble," the name of the thirty-first order in Linnæus's *Fragments of a Natural Method*.

VERB, in Grammar, a word serving to express what we affirm of any subject, or attribute to it.

VERDICT, the answer of a jury made upon any cause, civil or criminal, committed by the court to their examination; and this is two-fold, general or special. A general verdict is that which is given or brought into the court in like general terms to the general issue; as, guilty or not guilty generally. A special verdict is, when they say at large that such a thing they find to be done by the defendant or tenant as declaring the course of the fact, as in their opinion it is proved; and as to the law upon the fact, they pray the judgment of the court; and this special verdict, if it contain any ample declaration of the cause from the beginning to the end, is also called a verdict at large. A special verdict is usually found where there is any difficulty or doubt respecting the laws, when the jury state the facts as proved, and pray the advice of the court thereon. A less expensive and more speedy mode, however, is, to find a verdict generally for the plaintiff, subject, nevertheless, to the opinion of the judge, or the court above, or a special case drawn up and settled by counsel on both sides.

VERDIGRIS, is an acetate of copper, useful in the arts as a pigment.

VERGERS, certain officers of the courts of King's Bench and Common Pleas, whose business it is to carry white wands before the judges. There are also vergers of cathedrals, who carry a rod, tipped with silver, before the bishop, dean, &c.

VERJUICE, a liquor obtained from grapes or apples unfit for wine or cider; or from sweet ones whilst yet acid and unripe.

VERMES, in Natural History, the last class of the animal kingdom, according to the Linnæan system. The animals in this class are not merely those commonly known by the name of worms, but likewise those which have the general character of being "slow in motion, of a soft substance, extremely tenacious of life, capable of reproducing such parts of their body as may have been taken away or destroyed, and inhabiting moist places." There are five orders in this class, viz. the infusoria, intestina, mollusca, testacea, zoophyta.

VERMICELLI, a composition of flour, cheese, yolks of eggs, sugar, and saffron, reduced to a paste, and formed into long slender pieces like worms, by forcing it with a piston through a number of little holes.

VERMIN, a collective term which includes the various sorts of small animals that are injurious to the corn, fruit, and other produce of the farmer.

VERNIER, a scale adapted for the gradation of mathematical instruments.

VERSE. See **POETRY**.

VERSED SINE OF AN ARCH, a segment of the diameter of a circle, lying between the foot of a right sine and the lower extremity of the arch.

VERTICAL CIRCLE, in Astronomy, a great circle of the

sphere passing through the zenith and nadir, and cutting the horizon at right angles: it is otherwise called azimuth.

VERTICAL PLANE, in Perspective, is a plane perpendicular to the geometrical plane, passing through the eye, and cutting the perspective plane at right angles.

VESPERTILIO, the *Bat*, in Natural History, a genus of mammalia, of the order primates. Generic character: teeth erect, sharp-pointed, approximated; fore-feet palmated, with a membrane surrounding the body, and by which the animal is enabled to fly. Bats fly only by night, in quest of their food, consisting of gnats and moths, and when deprived of their eyes appear to feel no want of them, having a supplementary power of perception, by which they avoid objects in the way with nearly as much precision as in their perfect state. In cold climates they pass the winter in torpor, assembling in holes and in caverns, in which they are occasionally seen adhering in great numbers to the walls, and sometimes suspended by their hind legs. The bones of the extremities of the fore-legs of bats are continued into long and thin processes, connected by a fine and almost transparent skin, which they are enabled to unfold optionally for flight, or to withdraw into a very small compass, when they wish to repose. The general division is into those which have tails, and those which have none. There are twenty-five species.

VESSEL, a general name given to all the different sorts of ships which are navigated in the ocean, or in canals and rivers. It is, however, more particularly applied to those of the smaller kind, furnished with one or two masts.

VESTIBULE, in Architecture, a kind of entrance into a large building; being a place before the hall, or at the bottom of the staircase.

VESTRY, a place adjoining to a church, where the vestments of the minister are kept; also a meeting at such place where the minister, churchwarden, and principal men of most parishes, at this day make a parish vestry.

VESUVIAN, a mineral found in lava, especially at Vesuvius, and formerly confounded with hyacinth. Its colour is brown or greenish. It is found in masses, but usually crystallized in rectangular eight-sided prisms. The primitive form of its crystal is the cube. The specific gravity is from 3.39 to 3.4.

VIBRATION, in Mechanics, a regular reciprocal motion of a body, as a pendulum, &c. which, being freely suspended, swings, or oscillates, first this way, then that.

VICAR, one who supplies the place of another. The priest of every parish is called rector, unless the prædial tithes are appropriated, and then he is styled vicar, and when rectories are appropriated, vicars are to supply the rector's place. Prior to the Reformation, when the patronage of a parish was in the hands of a religious house, the monks usually detained the larger portion of the tithes, and appropriated a certain portion for the support of the vicar whom they appointed to perform the duties. Such tithes are now enjoyed by the vicar, and the other tithes by the lay impropriator, or other parties who inherit the property of the religious houses.

VICE, in Smithery, and other arts employed in metals, is a machine or instrument, serving to hold fast any thing they are at work upon, whether it is to be filed, bent, riveted, &c.

VICE, Hand, is a small kind of vice serving to hold the lesser works, that require often turning about.

Vice is also a machine used by the glassiers to turn or draw lead into flat rods, with grooves on each side to receive the edges of the glass.

VILLAIN, or **VILLEIN**, in our ancient customs, denotes a man of servile and base condition, viz. a bondman or servant; and there were anciently two sorts of bondmen or villains in England; the one termed a villain in gross, who was immediately bound to the person of his lord and his heirs; the other, a villain regardant to a manor, he being bound to his lord as a member belonging and annexed to the manor whereof the lord was owner; and he was properly a pure villain, of whom the lord took redemption to marry his daughter, and to make him free; and whom the lord might put out of his lands and tenements, goods and chattels, at his will, and beat and chastise, but not maim him.

VINEGAR, is a liquid of a reddish or yellowish colour, a pleasant sour taste, and an agreeable odour. Its specific gra-

vity varies from 1.0135 to 1.0251, and it differs also in its other properties, according to the liquid form in which it has been procured. It is very subject to decomposition; but Scheele discovered that if it is made to boil for a few moments, it may be kept afterwards for a long time without alteration. Besides acetic acid and water, vinegar contains several other ingredients, such as mucilage, tartar, a colouring matter, and often also two or more vegetable acids. When distilled at a temperature not exceeding that of boiling water, till about two-thirds of it have passed over, all these impurities are left behind, and the product is pure acid diluted with water. See ACID and CHEMISTRY.

VINERY, in Gardening, a sort of garden erection, consisting of a wall twelve or fourteen feet high, extending from east to west, furnished with stoves, flues, a roof, and lights of glass, for the protection and cultivation of vines. The double vinery, in the Plate, is an improvement on the old system, the advantages of which must appear obvious on inspection. The buildings will be attended with some additional expense; but whenever a trial has been made, the experiment has fully answered every reasonable expectation.

VINEYARD, a plantation of vines.

VIOL, among sailors, the anchor rope, as it is thus pronounced, but which is more generally spelt *voyol*. This name is more particularly applied to a thick rope, which being attached to the cable, passes through a large block, and thence to the fore capstan: when it goes direct from the cable to the main capstan, it is more usually called the messenger.

VIOL, a stringed instrument, resembling in shape and tone the violin, of which it was the origin; that impressive and commanding instrument being little more than an improvement of the old viol.

VIOLA, a tenor violin. This instrument is similar in its tone and formation to the violin, but its dimensions are somewhat greater, and its compass a fifth lower in the great scale of sounds.

VOLIN, or FIDDLE, a well-known stringed instrument, of brilliant tone and active execution. The four strings of which it consists, are tuned in fifths from each other. The pitch of the lowest string is G, under the second ledger line in the treble stave; consequently that of the next is D, under the first line of the stave; the pitch of the next above that, A on the second space; and that of the upper string, E on the fourth space.

VIOLO\CELLO, a bass viol, containing four strings, the lowest of which is tuned to double C. The strings are in fifths, consequently the pitch of that next the gravest is C gamut; that of the next, D on the third line in the bass; and that of the upper string, A on the fifth line.

VISION. See OPTICS.

VITAL AIR. Pure air or oxygen, is one of the constituent parts of atmospherical air, and is useful in the germination of grain and seeds, the vegetation and growth of plants, and is essential to the support of animal life. In reference to the latter, it is inhaled by respiration; but on the nature of its operation there have been many theories, each of which has its advocates and followers, without being supported by conclusive arguments, or established on incontrovertible principles.

VITRIFICATION. See GLASS.

VITRIOL, MARTIAL, or *Sulphat of Iron*. In commerce it is usually denominated green vitriol or copperas. It is not prepared by dissolving iron in sulphuric acid, but by moistening the pyrites, which are found native in abundance, and exposing them to the open air. They are slowly covered with a crust of sulphat of iron, which is dissolved in water, and afterwards obtained in crystals by evaporation. Sometimes the salt is found ready-formed, either in a state of solution in water, or mixed with decayed pyrites. In some cases it is found necessary to roast the pyrites before they can be made to undergo spontaneous decomposition. Sulphat of iron has a fine green colour. Its crystals are transparent rhomboidal prisms, the faces of which are rhombs, with angles of 79 deg. 50 min. and 100 deg. 10 min. inclined to each other at angles of 98 deg. 37 min. and 81 deg. 23 min. It has a very strong styptic taste, and always reddens vegetable blues. Its specific gravity is 1.8399. It is soluble in about two parts of cold water, and in $\frac{1}{4}$ ths of its weight of boiling water. It is insoluble in alcohol.

VOLCANO, in Natural History, a burning mountain, or one that occasionally vomits forth fire, flame, ashes, cinders, &c. Volcanoes are peculiar to no climate, and have no necessary connexion with any other mountains, but seem to have some with the sea, being generally in its neighbourhood; they frequently throw out matter which belongs to the sea, as the relics of fishes, sea-weed, and sometimes sea-water itself. The most celebrated volcanoes are those of Etna and Vesuvius.

VOLCANOES IN THE MOON. As the moon has on its surface mountains and valleys in common with the earth, some modern astronomers have discovered a still greater similarity, viz. that some of these are really volcanoes emitting fire as those on the earth do. An appearance of this kind was discovered some years ago by Don Ulloa in an eclipse of the sun. It was a small bright spot, like a star, near the margin of the moon, and which he at that time supposed to have been a hole, with the sun's light shining through it. Succeeding observations, however, have induced astronomers to attribute appearances of this kind to the eruption of volcanic fire; and Dr. Herschel has particularly observed several eruptions of the lunar volcanoes.

VOLLEY OF SMALL ARMS, a discharge of several muskets at the same instant.

VOLTAISM. See GALVANISM.

VOLUNTEER, implies a man who, being in the king's service, freely offers himself to serve in a particular expedition of danger and fatigue.

VOLUTE, a spiral scroll, used in the Ionic and Composite capitals, whereof it makes the principal characteristic and ornament.

VORTEX, a whirlwind, or sudden rapid or violent motion of the air in gyres or circles. Sometimes it implies an eddy or whirlpool, or a body of water, in certain seas, or rivers which runs rapidly around, forming a sort of cavity in the middle.

VORTEX, in the Cartesian philosophy, is a system or collection of particles of matter, moving the same way, and round the same axis.

VOWEL, in Grammar, a letter which affords a complete sound in itself. In our language there are six in number, *a, e, i, o, u*, and *y*.

VOYAGE, any distance passed, or to be passed, at sea.

VULCANIC THEORY OF THE EARTH. This theory, also called Plutonic, in opposition to the Neptunian theory, (which supposes all matter to have formerly been dissolved in a fluid, and to have gradually been deposited in the forms in which we now find it,) supposes, that, formerly the world was in a fluid state, by the power of heat; on the abatement of which, rocks became solid; and that the inequalities of surface of hills and mountains have been caused by the force of internal fire elevating them above the common level. It assumes that, at great depths in the mineral regions, an immense heat is constantly present, and that this heat operates in the fusion and the consolidation of the substances deposited. To the action of this heat, the formation of all our strata is attributed. They are conceived to be the wrecks of a former world, which have been more or less perfectly fused by this agent, and by subsequent cooling have been consolidated. The subterraneous fire being placed at immense depths, the substances on which it operates must be under a vast pressure. This prevents their volatilization in whole or in part, and from this circumstance it explains appearances, in minerals and qualities, which they possess, which would otherwise appear inconsistent with the supposition of their being formed by fire.

VULGATE, a very ancient Latin translation of the Bible, and the only one the church of Rome acknowledges authentic. It is by St. Jerome, and was made almost word for word from the Greek of the LXX. The author of the version is not known, nor so much as guessed at.

Vulgate of the New Testament.—This the Romanists generally hold preferable to the common Greek text, in regard it is this alone, and not the Greek text, that the Council of Trent had declared authentic. Accordingly that church has, as it were, adopted this edition. The priests read no other at the altar, the preachers quote no other in the pulpit, nor the divines in the schools.

VULTUR, the *Vulture*, in Natural History, a genus of birds of the order accipitres.

of a Double Vinery.

Elevation.

0 10 20 30 Feet

A. Front and Back Walls

B. Path for a Drop of Pipe or Trough, in Pots, and Bush-rooms under them. To be filled with fresh dung at the beginning of forcing the Vines; which will be of essential service to the Vines, and ensure a crop.

C. Stone Parapet

D. Border for the Vines to run in.

The Front to open against the Back Wall. Crops fit for cutting in April and May.

E. Open Shed behind the Vinery. F. Fire House.

W.

W, is the twenty-first letter of our alphabet.

WACKEN, a mineral that occurs in mass; sometimes it forms strata, but more frequently it runs in veins. Colour dark greenish-gray, which often passes to mountain-green, or blackish-green. Specific gravity from 2.5 to 2.9. Easily melts before the blowpipe.

WAD, or **WADDING**, in Gunnery, a stopple of paper, hay, straw, old rope-yarn, or tow, rolled up like a ball, or a short cylinder, and forced into a gun to keep the powder close in the chamber; or put up close to the shot, to keep it from rolling out.

WAFERS, To **MAKE**:—Take very fine flour, mix it with white of eggs, isinglass, and a little yeast; mingle the materials; beat them well together; spread the batter, being made thin with gum-water, on even tin plates, and dry them in a stove, then cut them out for use. You may make them of what colours you please, by tingeing the paste with brazil or vermillion for red; indigo or verditer, &c. for blue; saffron, turmeric, or gamboge, &c. for yellow.

WAF, a signal displayed from the stern of a ship for some particular purpose, by hoisting the ensign furled up together into a long roll, to the head of its staff, or to the mizzen-peck. It is particularly used to summon the ship's boats off from the shore.

WAGERS. In general a wager may be considered as legal, if it is not an incitement to a breach of the peace, or to immorality; or if it does not affect the feelings or interest of a third person, or expose him to ridicule; or if it is not against sound policy.

WAGES, what is agreed upon by a master to be paid to a servant, or any other person that he hires to do his business for him.

WAIST, that part of a ship which is contained between the quarter-deck and fore-castle, being usually a hollow space, with an ascent of several steps to either of those places. When the waist of a merchant ship is only one or two steps of descent from the quarter-deck and fore-castle, she is said to be galley-built; but when it is considerably deeper, as with six or seven steps, she is called frigate-built.

WAIST Cloths, coverings of canvass or tarpauling for the hammocks, which are stowed on the gangways, between the quarter-deck and fore-castle.

WAISTERS, people stationed in the waist in working the ship; and as they have little else of duty but pulling and hoisting, they are, for the most part, selected from the strongest landmen and ordinary seamen.

WAKE of a **SHIP**, the smooth water astern when she is under sail; this shews the way she has gone in the sea, whereby the mariners judge what way she makes. For if the wake is right astern, they conclude she makes her way forward, but if the wake is to leeward a point or two, then they conclude she falls to the leeward of her course.

WALE, or **WALE**, in a **Ship**, those outermost timbers in a ship's side, on which the sailors set their feet in climbing up. As the wales are framed of planks broader and thicker than the rest, they resemble ranges of hoops encircling the sides and bows. They are usually distinguished into the main-wale and the channel-wale; the former is below the lower-deck ports, and the latter between the top of those ports and the sills of the upper-deck ports. The situation of the wales being ascertained by no invariable rule, is generally submitted to the judgment and fancy of the builder; but the position of the gun-ports and scuppers ought to be particularly considered, that the wales may not be wounded by too many breaches.

WALES, **WILLIAM**, a respectable mathematician, who accompanied Cook in his first voyage round the world, as astronomer, and was afterwards appointed mathematical master at Christ's hospital. He was author of an Account of Astronomical Observations in the Southern Hemisphere, 4to.; &c. Wales died in 1790.

WALLIS, **Dr. JOHN**, an eminent English mathematician, was born at Ashford in Kent, in 1616, and died in Oxford in 1703, in the 88th year of his age. Dr. Wallis was the author of several ingenious and learned works, on various branches of the mathematics.

WALL-SIDED, the figure of a ship's side when, instead of being incurvated, so as to become gradually narrower towards the upper part, it is nearly perpendicular to the surface of the water, like a wall. In ship-building, this was formerly called wall-reared.

WAPENTAKE, from the Saxon, the same with what we call a hundred, and more especially used in the northern counties beyond the river Trent.

WAR. The too frequent recurrence of this great and detestable calamity, unfortunately renders a definition of the word unnecessary. If we were called upon to define it, we would say, it is the wanton destruction, the cold-blooded slaughter, of the human race: we should call it an accumulation of every sin that degrades and vilifies mankind: we should mark it as a practice that diffuses misery, and perpetuates vice; we should say, that if there is a burlesque upon the boasted reason of man, it is this—when millions meet to murder each other for a quarrel, in which, in general, they have not individually the smallest interest. The poet who wrote

“One murder makes a villain, millions a hero,” &c.

deserves a statue of gold; and the writer of that verse may lift his head in the proudest assembly, and avow his principles in the face of the world.

WARDEN, one who has the charge of keeping of any person or thing by office.

WARDMOTE, in London, is a court so called which is kept in every ward of the city.

WARE, (To) or **WEAR**, to cause a ship to change her course from one board to the other, by turning her stern to the wind. Hence it is used in the same sense of veering, and in opposition to tacking, wherein the head is turned to the wind, and the stern to leeward. Since by this movement the ship loses considerably more ground than by tacking, it is rarely practised, except in cases of necessity, or for delay, as when the violence of the wind and sea renders tacking impracticable, or when the course is slackened to wait for a pilot, or for some other ship, &c. In order to wear or veer the ship, the after sails are brailed up, or made to shiver in the wind, whilst the head sails are increased, the helm being put hard a-weather, or to windward: by which means the forepart is turned about from the wind; but as soon as the wind will act upon that quarter, which was before to leeward, the after sails must be extended so as to receive the greatest impulse, whilst the head sails are brailed obliquely, whereby the vessel will wheel round, with her bow to windward, and become close-hauled upon the contrary tack to that on which she formerly stood. When the tempest is so violent as to prevent the use of sails, the effort of the wind operates almost equally on the opposite ends of the ship, so that the masts and yards situated at the head and stern counterbalance each other. The effect of the helm is also considerably diminished; because the head way, which gives life and vigour to all its operations, is at this time feeble and ineffectual. Hence it is necessary to destroy this equilibrium, which subsists between the mast and yards afore and abaft, and to throw the balance forward in order to prepare for veering or wearing. This is accordingly performed by bracing the foremost yards across the direction of the wind, and arranging those on the main mast and mizzen mast directly in the line of the wind. If this expedient proves unsuccessful, and it is absolutely necessary to wear, in order to save the ship from destruction by oversetting or running ashore, the mizzen mast must instantly be cut away, and even the main-mast, if she yet remains incapable of answering by bearing away before the wind.

WARP is the Manderment in the French, whether of silk, wool, cotton, &c. and is the greatest expansion in the weaving loom, and arises when the weftman by means of his shuttle passes the threads of the warp in form a close, ribbed surface, or other stuff.

WARP is a rope or string, employed occasionally to remove a star from one place to another in a port, road, or river. Hence *To Warp*, is to change the situation of a ship, by pulling her from one part of a harbour, &c. to some other, by means of warps which are attached to buoys or other things, to anchors, &c. in the bottom, or to certain stations upon the shore, as piers, rings, trees, &c.

WARRANT a writ, under hand and seal, to bring any offender before the person granting it; and warrants of commitment are issued by the privy council, a secretary of state, or justice of the peace, &c. when there has been a private information, or a witness has deposed against an offender. A warrant from any one of the justices of the Court of King's Bench extends over all the kingdom, and is tested or dated England, but a warrant of a justice of peace in one county, must be backed, that is, signed, by a justice of another county, before it can be executed there: and a warrant for apprehending an English or a French offender, may be indorsed in the opposite kingdom, and the offender carried back to that part of the united kingdom in which the offence was committed. This is also now extended to Ireland, upon a proper certificate of an indictment or information filed in either country.

WARRANT of an Attorney, is an authority and power given by a client to his attorney, to appear or plead for him: or to suffer judgment to pass against him by confessing the action by *nil culit, non sum informatus*, &c.

WARRANT, the name given to a kind of commission or authority to those officers appointed by the Navy-Board, while the authorities granted by the Admiralty are styled commissions. Hence, a *Warrant Officer*, is an officer holding a warrant from the Navy-Board; such are the master, surgeon, purser, boatswain, gunner, carpenter, &c.

WARRANTY, a promise or covenant by deed, made by the bargainer, for himself and his heirs, to warrant or secure the bargainee and his heirs against all men, for the enjoying any thing agreed on between them.

WARREN, is a franchise, or place privileged by prescription or grant from the king, for the keeping of beasts and fowls of the warren; which are conies, partridges, pheasants, &c.

WASH, among Distillers, the fermentable liquor used by malt distillers.

WASH Board, a broad thin plank, fixed occasionally on the top of a boat or other small vessel's side, so as to increase the height thereof, but may be removed at pleasure. It is used to prevent the sea from breaking into the vessel in rough weather.

WASTE, is the committing of any spoil or destruction in houses, lands, &c. by tenants, to the damage of the heir, or of him in reversion or remainder; whereupon the writ or action of waste is brought for the recovery of the thing wasted, and damages for the waste.

WATCH, a small portable machine for measuring time; having its motion commonly regulated by a spiral spring. Perhaps, strictly speaking, watches are all such movements as shew the parts of time; as clocks are such as publish them by striking on a bell, &c. But commonly the term watch is appropriated to such as are carried in the pocket; and clock to the large movements, whether they strike the hour or not.

Spring or Pendulum WATCHES, stand pretty much on the same principle with pendulum clocks. For if a pendulum describing small circular arcs, make vibrations of unequal lengths in equal times, it is because it describes the greater arc with a greater velocity; so a spring put in motion, and making greater and less vibrations as it is more or less stiff, and as it has a greater or less degree of motion given it, performs them nearly in equal times. Hence, as the vibrations of the pendulum had been applied to large clocks, to rectify the inequality of their motions; so to correct the unequal motions of the balance in watches, a spring is added, by the isochronism of whose vibrations the correction is to be effected. The spring is usually wound into a spiral; that, in the little compass allotted it, it may be as long as possible; and may have strength enough

not to be mastered, and dragged about by the inequalities of the balance it is to regulate. The vibrations of the two parts, viz. the spring and the balance, should be of the same length: and so adjusted, as that the spring, being more regular in the length of its vibrations than the balance, may occasionally compensate its irregularity to the latter.

Striking Watches, are such as, besides the proper watch-part adapted to the measuring of time, have a clock part for striking the hours, &c.

Repeating Watches, are such as by pulling a string, &c. repeat the hour, quarter, or minute, at any time of the day or night.

Of the Mechanism of a Watch, properly so called. Watches, as well as clocks, are composed of wheels and pinions, and a regulator to direct the quickness or slowness of the wheels, and of a spring which communicates motion to the whole machine. But the regulator and spring of a watch are vastly inferior to the weight and pendulum of a clock, neither of which can be employed in watches. Instead of a pendulum, therefore, we are obliged to use a balance (plate, fig. 1.) to regulate the motion of a watch: and a spring, fig. 2, which serves instead of a weight to give motion to the wheels and balance.

The wheels of a watch, like those of a clock, are placed in a frame formed of two plates and four pillars. Fig. 3, represents the inside of a watch, after the plate, fig. 4, is taken off. A is the barrel which contains the spring, fig. 2; the chain is rolled about the barrel, with one end of it fixed to the barrel A, fig. 5, and the other to the fusee B.

When a watch is wound up, the chain which was upon the barrel winds about the fusee, and by this means the spring is stretched; for the interior end of the spring is fixed by a hook to the immovable axis about which the barrel revolves; the exterior end of the spring is fixed to the inside of the barrel, which turns upon an axis. It is therefore easy to perceive how the spring extends itself, and how its elasticity forces the barrel to turn round, and consequently obliges the chain which is upon the fusee to unfold and turn the fusee; the motion of the fusee is communicated to the wheel C, fig. 5; then by means of the teeth to the pinion e, which carries the wheel D; then to the pinion d, which carries the wheel E; then to the pinion c, which carries the wheel F; then to the pinion f, upon which is the balance wheel G, whose pivot runs in the pieces A called the potance, and B called a follower, which are fixed on the plate fig. 4. This plate, of which only a part is represented, is applied to that of fig. 3, in such a manner that the pivots of the pinions enter into holes made in the plate, fig. 3. Thus the impressed force of the spring is communicated to the wheels; and the pinion f being then connected to the wheel F, obliges it to turn fig. 5. This wheel acts upon the palettes of the verge 1, 2, fig. 1, the axis of which carries the balance H H, fig. 1. The pivot I is in the end of the verge, enters into the hole e in the potance A, fig. 4. In this figure the palettes are represented; but the balance is on the other side of the plate, as may be seen in fig. 6. The pivot 3 of the balance enters into a hole of the cock B C, fig. 7, a perspective view of which is represented in fig. 8. Thus the balance turns between the cock and the potance c, fig. 4, as in a kind of cage. The action of the balance wheel upon the palettes 1, 2, fig. 1, is the same with what we have described with regard to the same wheel in the clock i. e. in a watch, the balance wheel obliges the balance to vibrate backwards and forwards like a pendulum. At each vibration of the balance, a palette allows a tooth of the balance wheel to escape; so that the quickness of the motion of the wheels is entirely determined by the quickness of the vibrations of the balance; and these vibrations of the balance and motion of the wheels are produced by the action of the spring.

But the quickness or slowness of the vibrations of the balance depends not solely upon the action of the great spring, but chiefly upon the action of the spring a, b, c, called the spiral spring, fig. 9, situated under the balance H, and represented in perspective, fig. 6. The exterior end of the spiral is fixed to the pin a, fig. 9. This pin is applied near the plate in a, fig. 6: the interior end of the spiral is fixed by a peg to the centre of the balance. Hence if the balance is turned upon itself, the plates remaining immovable, the spring will extend itself, and make the balance perform one revolution. Now, after the spiral is thus extended, if the balance be left to itself, the elasticity

Mechanism of the Common Watch.

p. 183

Barn. Hill. p. 183

of the spiral will bring back the balance, and in this manner the alternate vibrations of the balance are produced.

In fig. 5, all the wheels above described are represented in such a manner, that it may be easily perceived at first sight how the motion is communicated from the barrel to the balance.

In fig. 10 are represented the wheels under the dial-plate by which the hands are moved. The pinion *a* is adjusted to the force of the prolonged pivot of the wheel *D*, fig. 5, and is called a cannon pinion. This wheel revolves in an hour. The end of the axis of the pinion *a*, upon which the minute hand is fixed, is square; the pinion fig. 10, is indented into the wheel *b*, which is carried by the pinion *a*. Fig. 11, is a wheel fixed upon a barrel, into the cavity of which the pinion *a* enters, and upon which it turns freely. This wheel revolves in twelve hours, and carries along with it the hour-hand.

Such in brief is the general mechanism of a watch; to treat the subject to the extent its importance demands would require a volume: some parts of the construction are further explained under the words *BALANCE* and *SCAPEMENT* in this volume.

Mr. Elliot of Clerkenwell has lately invented a very simple repeating watch, in which the motion is performed with much fewer parts than in the usual construction, by which means he is enabled to reduce the price so low as eight guineas for a good repeater on this principle, or to add the repeating work to another watch for three.

The method by which this repeater is so much simplified is by the use of a single part, so contrived as to perform the operations of several: this is a flat ring, or centreless wheel, of nearly the same diameter as the watch, supported in its place, so as to admit of circular motion, by four grooved pulleys placed round its external circumference, in the same manner as the part in common clocks which denotes the moon's age. This part is put in motion by turning the pendant, whose extremity is formed into a small vertical wheel, which works in teeth cut on the external part of the flat ring for almost a third of its circumference. The lower part of the ring contains the pins, at right angles to its face, which lift the hammers for striking the hours and quarters; the internal part of the ring contains indentations of regularly increasing depths, which receive the tails of the levers, whose other extremities are pressed by their springs against the hour-snail and the quarter-snail, is by them prevented from moving beyond a certain degree proper for the time: after the pendant is turned, the ring is brought back to its first position, by a box spring, round which a fine chain is coiled, whose extremity is connected with the inner part of the ring. By turning the pendant to the left the hour is struck, and by turning it to the right the quarters are repeated; and the returning spring just mentioned is made to operate in both directions, by its chain passing between two little pulleys, which on either side convert the direction of the chain to the line of traction of the spring. Hence it is evident this single flat ring performs all the following operations. 1. It receives the motion for striking the hour from the pendant. 2. The same for striking the quarters. 3. It carries the pins or teeth, which lift the hour-hammer. 4. The same for the quarter-hammer. 5. It contains the indentations by which the hour snail operates on it by its lever. 6. The same by which the quarter-snail operates on it. 7. It carries the part that recoils the movement which tells the hour to its first position. 8. It carries the part for the same purpose, for the quarter movement. 9. It contains a cavity, which moves over a fixed pin, that prevents the pendant from turning it too far. In this ring, the same parts in three instances are made to perform double operations, by which simplicity of construction is advanced, apparently, to its greatest extent.—*Dr. Gregory's Mechanics.*

WATCH, in the art of War, a number of men posted at any passage, or a company of the guards who go on the patrol. At sea, the term watch denotes a measure or space of four hours, because half the ship's company watch and do duty in their turns, so long at a time, and they are termed starboard watch, and larboard watch. These epithets allude to the situation of their hammocks when hung up; the two watches are, however, occasionally separated into three or four divisions, as in a road, for an anchor-watch, &c. But the officers of the navy usually divide themselves into three watches, in order to lighten their duty.—*Starboard Watch, Hoay! Starboard Lines, Hoay!*

Larboard Watch, Hoay! Larboard Lines, Hoay! are exclamations used by the boatswain's mates when summoning their respective watches upon deck, to relieve each other.

Anchor WATCH, is a small guard kept constantly upon deck, while the ship rides at single anchor. *Dog Watches*, are the two reliefs which take place between four and eight o'clock in the afternoon, each of which is only two hours; the intent of these watches is to change the turn of the night watch every twenty-four hours. The *First Watch*, is from eight o'clock in the evening till twelve at night. The *Middle Watch* continues from twelve till four in the morning. The *Morning Watch* comprehends from four to eight o'clock in the morning. See *Nautical Day*, p. 214. A buoy is said to watch, when it continues floating upon the surface of the sea.

WATCH, is also a word used in throwing the deep-sea lead, when each man, on letting go the last turn of line in his hand, calls to the next abast him "Watch."

WATCH Glasses, are the glasses employed to measure the period of the watch, or to divide it into any number of equal parts, as hours, half-hours, &c. so that the several stations therein may be regularly kept and relieved, as at the helm, pump, look-out, &c. See the article *GLASS*.

WATCHMAN'S NOCTUARY, the name given to an instrument lately contrived to remedy a great defect in an important branch of the police of great cities, that of night-watching. Every twenty-four hours furnishes some instance of the inefficiency of the present system, by the depredations which have been committed in the night, or by the fatal accidents which occur from a neglect of giving families timely warning in cases of sudden fires. A respectable magistrate (Samuel Day, Esq. of Charter House, Hinton, Somersetshire) has directed his attention to the application of a mechanical check upon the diligence and regularity of watchmen, labourers, and all other classes of men whose duty requires that they should attend at certain places at appointed times; the instrument he has invented for this purpose he calls a *Watchman's Noctuary, or Labourer's Regulator*.

The invention consists principally of a large horizontal wheel, which is moved uniformly round every twelve hours by clock-work. The upper side of this wheel is divided by two circles, one within the other; the outer one, or periphery, having the hours and quarters marked on it, which may be called the lateral side; the inner circle having also a dial, which may be called the vertical one. The space between these circles or dials is divided into cells, each cell corresponding with a quarter or half-hour of the different hours marked on the dials; and if thought proper, the cells might be so multiplied, as that each would correspond within a period of five minutes. Such is the upper side of the horizontal wheel, which may be made of copper, or tin, or various other materials, and is about 9 inches in diameter. The under side of the same has a brass wheel with teeth, diameter $3\frac{1}{2}$ inches, fixed to its central part; the teeth of which, letting in with those of a smaller wheel or pinion, give motion in consequence to the large horizontal wheel (of which it forms a part) by the motion it receives from the pinion. This pinion being set in motion by the common clock-work and a weight or spring, the revolution of the horizontal wheel is completed once in twelve hours, and thus regularly goes round, will at all times shew the time of day or night. As it moves round it carries the cells above mentioned under a kind of chink, just large enough to receive a token of about the size of a farthing. This chink sinks down from an external brass box, which is sufficiently large to admit a man's fingers to drop in the token by an external aperture or mouth of the chink, the token being directed perpendicularly through this chink into such cell as is immediately under it, and which must correspond with the time of night or day. The head of the case of the machine has double doors in front; the outward door covers the whole face together, leaving a sufficient space above the horizontal wheel for examining the tokens and taking them from the cells, or for removing the wheel when necessary. A smaller door opens in this large one upon the brass box abovementioned, the opening of which belongs solely to the watchman, or such other person as may be required to use the same, for the purpose of seeing the time and dropping his tokens, a minute dial also being placed under the hour-index. If it be found more

convenient, a common dial plate, to shew the hours and minutes, may be placed instead of the minute dial. The great outer door first mentioned is to be opened only by the inspector or examiner of the tokens, and ought to be well secured; but for greater safety, both against thieves and weather, there is an inside door, in which the fore-mentioned brass box is fixed; and this inner door being opened, throws into view the horizontal wheel for the purpose just specified. These are the essential parts of the invention; the different appendages may be variously modified. One such instrument as this being placed at each end of a watchman's round, it will be ascertained how the man continued his movements through the night, to a nicety of ten minutes (or less if required) at any period of the watch; and the slightest irregularity or omission will be detected the next morning by the person whose office it shall be to open the machine. No trick or fraud on the watchman's part can counteract the movement of the horizontal wheel comprising the cells into which the tokens are to be dropped; each cell is, by this contrivance, like time itself, irrevocable when past: the watchman has no command over it, and the whole will be a kind of speaking witness of his diligence and fidelity in going his rounds, answering the next morning to the exact periods he either was or ought to have been there.

The same machine will answer in custom-houses, ware-houses, banking-houses, manufactories, bleaching-grounds, and every place where watching or other attendance, to be useful, must be exact: even sentinels on military duty might be required to leave tokens as memorials of their vigilance.

Mr. Day obtained the usual patent for securing to himself the right of making and selling this instrument; yet surely not to the exclusion of others invented for the same purpose: for the late Marquis of Exeter informed the public years ago, through the medium of Nicholson's Philosophical Journal, that a clock for a similar purpose had been invented by Messrs. Boulton and Watt of Birmingham, which cost no more than thirty shillings. His lordship had then had two of them at Burlington Hall more than four years; and he gives the following description of them: "They go eight days, and have a face like a clock, but do not strike. The dial goes round, and the hour-finger is fixed: round the edge of the dial are moveable iron pins, corresponding with the quarters in each hour. A small hammer placed behind the hour-finger, when moved downwards, pushes into the dial one of the pins which happens to be under it at the time, which pin remains so abased until the dial nearly returns to the same place, when by an enclosed plane the pin is raised up into its first position. This gives time to have the machine examined in the morning, to see how many pins have been struck, and at what time they were pushed downwards. The hammer is moved by the pulling of a chain with a handle, like house-door bells, which, by cranks and wires, is attached to it. I have one in my library, the handle is out of doors. The other machine is placed in a building at the other end of my premises."

WATER, a transparent fluid without colour, smell, or taste; in a very small degree compressible; when pure, not liable to spontaneous change; liquid in the common temperature of our atmosphere, assuming a solid form at 32° Fahrenheit, and a gaseous at 212°, but returning unaltered to its liquid state on resuming any degree of heat between these points; it is capable of dissolving a greater number of natural bodies than any other fluid whatever, and especially those known by the name of the saline; performing the most important functions in the vegetable and animal kingdoms, and entering largely into their compositions as a constituent part.

Water exists, therefore, in three different states: in the solid state, or state of ice,—in the liquid,—and in the state of vapour or steam. It assumes the solid form, as observed above, when cooled down to the temperature of 32°, in which state it increases in bulk, and hence exerts a prodigious expansive force, owing to the new arrangement of its particles, which assume a crystalline form, the crystals crossing each other at an angle of 60° or 120°. The specific gravity of ice is therefore less than that of water. When ice is exposed to a temperature above 32°, it absorbs caloric, which then becomes latent, and is converted into a liquid state, or that of water. At the temperature of 42°·6, water is at its maximum of density; and according to

some accurate experiments upon water in this state, a French cubic foot of it weighs 70 pounds 223 grains French, which is equal to 529452·9492 troy grains. An English cubic foot, at the same temperature, weighs 437102·4946 grains troy. By professor Robinson's experiments, it is ascertained, that a cubic foot of water, at the temperature of 55°, weighs 998·74 avoirdupois ounces, of 437·5 grains troy each, or about 1½ ounce less than 1000 ounces avoirdupois, which latter, however, is the usual estimate. When water is exposed to the temperature of 212°, it boils; and if this temperature be continued, the whole is converted into elastic vapour or steam. In this state it expands to about 1800 times its bulk when in the state of water, which shews what an astonishing expansive force it must exert when it is confined; and hence its application to the steam-engine, of which it is the moving power.

To ascertain the Contraction and Expansion of Water in Cooling.—Fill a thermometer tube with tepid water, and immerse it in a glass vessel containing water of the same temperature, in which a mercurial thermometer is placed. If the whole apparatus be now placed in a bed of snow, or in a frigorific mixture, the water in the tube will gradually contract, till the mercury shews the temperature of 40°; it will then begin to expand gradually until it becomes ice. From this simple experiment the reader may see, what is otherwise, however, a well established fact, that the specific gravity of water is greatest at 42°. The expansion of this fluid when cooled still further, is an exception to the general law of bodies expanding by heat and contracting by cold; and as we are unable to account for it, or refer it to any class of facts, it seems like a perpetual miracle, and may excite both our wonder and our gratitude whenever it is contemplated. It is in consequence of this miracle that ice swims on water, and does not sink down, choking up the streams and stopping the currents of the rivers, the continued flow of which is as necessary to the existence of the world as the circulation of blood is to our existence.

Rules for ascertaining the Impurity of Water. Water is rarely found in a perfectly pure state. It almost invariably contains some portion of earthy, saline, vegetable, animal, or metallic matter, which is derived from the substances over or through which it flows. These substances being more or less held in solution, filtration will of course only separate that which is undissolved and floating in it; ignorant persons should not therefore conclude because water has been filtered, that it is pure and fit for drinking; as it might contain a deadly quantity of lead in solution, and yet be perfectly bright and transparent. Most waters, however, that are turbid only require filtration to render them salubrious. The most certain and direct way of purifying water is by distilling it with some fresh charcoal. The impurity of water may be ascertained by comparing it with that which is known to be pure, or distilled water. Impure water is heavier than pure water. Impure water is thinner, has less fluidity, than pure water. Impure water has some taste, colour, or smell,—pure water has none. Impure water, that contains earthy and metallic salts, is called hard water, being not so soft to the touch as pure water, nor does it wet any substance so readily as pure water. In country places, where water is both plentiful and good, these distinctions may be deemed unimportant; but the impurity of water in some situations is of very serious moment, and felt (we believe) very generally throughout the metropolis. In Christ Church, Surrey, it is a subject of as much complaint, perhaps, as any where. The water as supplied from some of the metropolitan water-works is so grossly impure, that, in the absence of filtering, it can only be safely used in food or drink after it has been boiled, recooled, and allowed to settle for some time—a process which is not only attended with considerable trouble, but which necessarily deteriorates the quality of the water.

The following is a description of a method of filtering which may easily be adopted: Procure a cask somewhat less than a porter hogshead, but of a different shape, in order to give the better effect to the filtering process, being 40 inches deep on end and 20 inches in diameter at the top and bottom. Make then a second or false bottom, and perforate it by a three-quarter inch gouge with about 18 holes; groove it into the cask, about four inches from the undermost or real bottom, and cover it over with four plies of coarse flannel. Procure a quantity of coarse

drawing,) the seat on being pressed down, will cause the rod F to descend, and give motion to the lever G, H, which being connected with the lever or handle I of the three-way cock, by the intermediate rod K, will cause the handle I to describe an arc *a, d*, upwards to *d*, pointed to by the dotted outline of the handle or lever I in its elevated position,) and will keep it in that elevated position till the pressure be removed from the top of the rod F, when by the action of the spring Q, it will be brought back to its first situation.

Any machinist will see that different contrivances may be employed to give the requisite action to this part of the apparatus; the patentee, however, does not rest the utility of his invention on the particular structure of the connecting parts of his machinery, but on the employment of the three-way cock in place of the valves and cranks hitherto used in water-closets, and on the employment of his secondary reservoir. But in whatever way motion be given to the plug of the three-way cock to cause it to make about a sixth part of a revolution, as above stated, the communication between the secondary reservoir R, and a pan or bason A, is thereby shut off, and a communication is simultaneously opened between the reservoir R and the supply pipe P, which supply pipe is brought by any convenient course from the main reservoir, wherever it may be situated at some higher position. This last-mentioned communication being now open, the water descends from the main reservoir through the supply-pipe P, passes through the cock C and the pipe D, and then ascends into the secondary reservoir R, by which a degree of compression is given to the air contained therein, proportioned to the greater height of the water in the main reservoir. During the time that a person is on the sinking seat, the secondary reservoir receives its charge of water in the manner just mentioned, and is put in readiness to have the same discharged with considerable velocity, by the elasticity of the confined air, whenever the person rises from the seat; the compressed air, by its elastic force, then urging the water through the aperture B into the pan A, whence it removes the soil through the stink-trap T, to the soil pipe U, to be carried off to the cess pool.

The foregoing is what the patentee calls the more favourable arrangement and form of his apparatus—he prefers and adopts, however, another construction when circumstances will permit it, that is, when the main reservoir is sufficiently elevated to press the air contained above the surface of the water in the secondary reservoir, with the weight of a column of water of about ten or twelve feet in height. But when the main reservoir is not sufficiently elevated to give that degree of compression to the air which is required for an efficient quick expulsion of the water, he places the secondary reservoir as high as circumstances will permit, (four or five feet at least, but more if possible,) that he may establish a column of water between it and the pan A, to act by its mere weight as an impelling power, (when the cock C is put in its requisite position,) to force the water to pass from the secondary reservoir into A, with a proportioned velocity. That is, in this place he does not employ it air-tight, but open to the atmosphere.

That this may be the more easily understood, see plate, fig. 2, in which the communication is open between the secondary reservoir and the injection pipe N, the water being discharged, or having been injected through the pipe N into the pan or bason at A, by its own weight, under the common pressure of the atmosphere, acting upon it at the open orifice of the pipe or tube S, which ascends from the secondary reservoir through the main reservoir M M, almost to its top, which is open to the atmosphere. This pipe S answers also another good purpose, in certain circumstances; namely, when the main reservoir M M receives its supply from any source which at particular times, or by any accident, may cause an overflow, (and which often causes great damage,) the tube or pipe S then serving as a waste pipe to carry off the surplus waste through the secondary reservoir R, the pipe D, the cock C, and the injection pipe N, all of which, as has already been stated, are open so long as the sinking seat is not pressed on—that is, in other words, so long as the rod F (fig. 1,) is not depressed in such a manner as to turn the handle of the cock C, into the position marked by the dotted outline thereof. And here let it be observed, that as often as the position of the plug is altered, by depressing the end G, and

elevating the end H of the lever G H, fig. 1, the cock is brought back again to its former position by the action of the spring Q, as soon as the pressure is removed from the top of the rod F.

We need hardly notice, what is common to every similar combination of parts, namely, that the usual means of simple joints are employed in the said apparatus to facilitate motion, where necessary, at the junctions of the levers and rods, as at *a, b*, and *e*, and at the fulcrum *c*, of the lever G H, as may be seen by inspecting fig. 1.

Mr. Jordan has also introduced another improvement into the three-way cock, which should not pass without notice, as it may be applied with advantage to other purposes. It is simple, but at the same time very effectual in giving a quick passage to the water. He makes the shell or barrel, and plug of the cock, about $6\frac{1}{2}$ inches long and about 2 inches diameter at one end, and $1\frac{1}{2}$ inch at the other; and instead of cutting out of the plug such a piece as *m*, fig. 3, he removes a long piece *n*, as shewn in fig. 4.

One great advantage that attends the invention is, that where several water-closets may be required in large private buildings, in prisons, hospitals, or extensive manufactories, only one general reservoir is required, nor will the premises ever need to be loaded with any other water than that in the one main reservoir, all the secondary reservoirs being empty whenever the apparatus is not in operation. For the service of any number of water-closets, it is only necessary to connect a pipe for each, with the supply-pipe P, in order to convey water into the secondary reservoir appropriated to each closet respectively; and such is the convenience in fixing this apparatus, resulting from its simplicity, that these pipes, connected with the supply pipe P, may be carried in any direction—as behind skirting boards, up dark corners, or in any other course that may occasion the least cutting of walls or of floors—provided only that the closet be posited at the required depth below the main reservoir. The secondary reservoir is commonly made about 8 inches in diameter, and 2 feet long: the pipe P is common $\frac{1}{2}$ -inch lead pipe, inside diameter; the pipe D about $1\frac{1}{2}$ inch diameter; and the injection pipe N not less in its smallest part. The soil-pipe U is of the usual dimensions, namely, about four inches in diameter.

WATER Bailiff, is an officer in sea-port towns, appointed for the searching of ships; and in London the water bailiff has the supervising and search of fish brought thither, and the gathering of the toll arising from the Thames; his office is likewise to arrest men for debt, &c. or other personal or criminal matters upon the river Thames.

WATER Colours. The general or simple colours, and the various species of each, fit for painting in water colours, are as follows:

Whites: Constant white, white lead, flake white. **Blacks**: ivory black, lamp black. **Greens**: green hicc, sap green. **Blues**: indigo, smalt, Prussian blue, ultramarine, ultramarine ashes. **Browns**: umber, burnt umber, bistre, burnt terra de sienna, unburnt ditto. **Reds**: burnt ochre, Indian red, lake, vermillion, carmine, Indian lake. **Yellows**: English ochre, gamboge, pigment, Roman ochre, Italian pink, king's yellows.

WATER Course. A water course does not begin by prescription or assent, but begins *ex jure natura*, having this course naturally, and cannot be diverted.

WATER Borne, the state of a ship with regard to the water surrounding her bottom, when there is barely a sufficient depth of it to float her off the ground.

WATER Lines, horizontal lines, supposed to be drawn about the outside of the ship's bottom, close to the surface of the water on which she floats; they are, accordingly, higher or lower upon the bottom, in proportion to the depth of the column of water required to float her.

WATER-logged, the state of a ship, when, by receiving a great quantity of water into her hold, by leaking, &c. she has become heavy and inactive upon the sea, so as to yield without resistance to the efforts of every wave rushing over her decks. In this dangerous situation there is no resource for the crew, except to free her by the pumps, or to abandon her by getting into the boats; for the centre of gravity is no longer fixed, but fluctuating from place to place; the ship entirely loses her stability, and is almost totally deprived of the use of her sails,

WAVE, in Physics, a volume of water elevated by the action of the wind, &c. upon its surface, into a state of fluctuation, and accompanied by a cavity. The extent from the bottom, or lowest point of one cavity, and across the elevation, to the bottom of the next cavity, is the breadth of the wave. Waves are considered as of two kinds, which may be distinguished from one another by the names of natural and accidental waves. The natural waves are those which are regularly proportioned in size to the strength of the wind which produces them. The accidental waves are those occasioned by the winds reacting upon itself by repercussion from hills or high shores, and by the dashing of the waves themselves, otherwise of the natural kind, against rocks and shoals; by which means those waves acquire an elevation much above what they can have in their natural state.

Motion of the Waves.—This makes an article in the Newtonian philosophy, that author having explained their motions, and calculated their velocity from mathematical principles, similar to the motion of a pendulum, and to the reciprocation of water in the two legs of a bent and inverted syphon or tube. His propositions concerning such canal, or tube, is the forty-fourth of the second book of his Principia, and is this: "If water ascend and descend alternately in the erected legs of a canal or pipe; and a pendulum be constructed whose length, between the point of suspension and the centre of oscillation, is equal to half the length of the water in the canal; then the water will ascend and descend in the same time in which the pendulum oscillates." The author hence infers, in prop. 46, that the velocity of waves is in the subduplicate ratio of their breadths; and in prop. 46, he proceeds to find the velocity of waves, as follows: "Let a pendulum be constructed whose length between the point of suspension and the centre of oscillation is equal to the breadth of the waves, and in the time that the pendulum will perform one single oscillation the waves will advance forward nearly a space equal to their breadth. That which is called the breadth of the waves being the transverse measure lying between the deepest part of the hollows, or between the tops of the ridges."

Let A B C D E F represent a stagnant water ascending and descending in successive waves. Also let A, C, E, &c. be the tops of the waves; and B, D, F, &c. the intermediate hollows. Because the motion of the waves is carried on by the successive ascent and descent of the water: so that the parts of it, as A, C, E, &c. which are highest at one time, become lowest immediately after, and because the motive force, by which the highest parts descend and the lowest ascend, is the weight of the elevated water, that alternate ascent and descent will be analogous to the reciprocal motion of the water in the canal, and observe the same laws as to the times of its ascent and descent, and therefore, (by prop. 44, above mentioned,) if the distances between the highest places of the waves A, C, E, and the lowest B, D, F, be equal to twice the length of any pendulum, the highest parts, A, C, E, will become the lowest in the time of one oscillation, and in the time of another oscillation will ascend again. Therefore between the passage of each wave, the time of two oscillations will intervene; that is, the wave will describe its breadth in the time that the pendulum will oscillate twice; but a pendulum of four times that length, and which therefore is equal to the breadth of the waves, will just oscillate once in that time, Q. E. I.

Corol. 1. Therefore waves, whose breadth is equal to $39\frac{1}{2}$ inches, or $3\frac{3}{4}$ feet, will advance through a space equal to their breadth in one second of time; and therefore in one minute they will go over a space of 195 feet; and in an hour a space of 11737 feet nearly, or two miles and almost a quarter.

Corol. 2. And the velocity of greater or less waves will be augmented or diminished in the subduplicate ratio of their breadth.

But waves never emerge and sink again in the same place. They seem to take their origin from some agitated spot, and appear thence to advance in expanding concentric circles. The subaqueous propulsion accompanying them decides no

doubt the direction of their progress, and prevents them from remaining in a pendulous state. If we examine attentively the motion of a wave, we shall find that the fore-part is always in the act of rising, while the hinder part is constantly sinking. The whole system hence appears to roll onwards, though there is actually no translocation of any portion of the mass, and each particle in succession merely oscillates with nearly a vertical ascent and descent. The motions of waves are perfectly imitated on the stage, by turning slowly an open helical screw applied round an horizontal axis. This effect is produced by the varying rate of the vertical elevation and depression, which must be as the versed sine of the distances of each point from the summit. Its celerity is greatest in emerging from the level of the water; it becomes stationary when it has gained its utmost ascent; but it again acquires an equal and opposite celerity as it sinks under that level, till it comes to pause at the limit of depression. The figure and apparent motion of a wave hence result from this unequal and reciprocating vertical play of each particle, combined with the continued and uniform advance of the inciting energy.

WAX. The upper surface of the leaves of many trees is covered with a varnish which may be separated and obtained in a state of purity, and found to possess all the properties of bees-wax; hence it is justly inferred that wax is a vegetable product, and that the bees extract it unaltered from the leaves of trees and other vegetable substances that contain it. Several plants contain wax in such abundance as to make it worth while to extract it from them.

WAY, a road or passage. A way may be by prescription, as if the owner and occupiers of such a farm have immemorially used to cross another's ground; for this immemorial usage supplies an original grant. A right of way may also arise by act and operation of law; for if a man grants to another a piece of ground in the middle of his field, he at the same time tacitly gives him a way to come at it, for where the law gives anything to any person, it gives by implication whatever is necessary for enjoying the same.

WAY OF A SHIP, the course or progress which she makes on the water when under sail. Thus, when she begins her motion, she is said to be under way; and when that motion increases, she is said to have fresh way through the water. Hence also, she is said to have head way, or stern way, to gather way, or to lose way, &c.

WAYGHTES, or **WAITS**. This noun formerly signified beat-boys; and which is remarkable, has no singular number. From the instruments, its signification was, after a time, transferred to the performers themselves; who being in the habit of parading the streets by night with their music, occasioned the name to be applied generally to all musicians who followed a similar practice. Hence those persons who annually, at the approach of Christmas, salute us with their nocturnal concerts, were and are to this day called wayghtes.

WEATHER, the state of the atmosphere with regard to the degree of wind, to heat or cold, or to dryness and moisture, but particularly to the first. Mr. Kirwan, in vol. v. of the Transactions of the Irish Academy, has laid down the following rules, as the result of a careful examination of observations which had been made in England, during a period of 112 years.

1. When no storm has either preceded or followed the vernal equinox, the succeeding summer is generally dry, or at least so, five times out of six.

2. If a storm happen from an easterly point, on the 19th, 20th, or 21st day of May, the ensuing summer will, four times in five, be also dry. The same event generally takes place, if a storm arise on the 25th, 26th, or 27th days of March, in any point of the compass.

3. Should there be a storm, either at south-west or at west-south-west, on the 19th, 20th, 21st, or 22d of March, the following summer is wet, five times out of six.

In England, if the winters and springs be dry, they are generally warm; on the contrary, dry summers and autumns are usually hot; as moist summers are cold. Thus, if the humidity or dryness of a particular season be determined, a tolerably correct idea may be formed respecting its temperature. To these indications may be added the following maxims; which, being the result of observations made by accurate

inquirers, may so far be depended upon, as they will afford a criterion of the mildness or severity, and of the dryness or moisture, of future seasons.

1. A moist autumn, succeeded by a mild winter, is generally followed by a dry and cold spring; in consequence of which, vegetation is greatly retarded.

2. Should the summer be uncommonly wet, the succeeding winter will be very severe; because the heat or warmth of the earth will be carried off by such unusual evaporation. Farther, wet summers are mostly attended with an increased quantity of fruit on the white-thorn and dog-rose; nay, the uncommon fruitfulness of these shrubs is considered as the presage of an intensely cold winter.

3. A severe winter is always indicated by the appearance of cranes and other birds of passage at an early period in autumn; because they never migrate southwards, till the cold season has commenced in the northern regions.

4. If frequent showers fall in the month of September, it seldom rains in May; and the reverse.

5. On the other hand, when the wind often blows from the south-west, during either summer or autumn; when the air is unusually cold for those seasons, both to our sensations, and by the thermometer; at the same time, the mercury being low in the barometer;—under these conditions, a profuse fall of rain may be expected.

6. Great storms, rains, or other violent commotions of the clouds, produce a kind of crisis in the atmosphere; so that they are attended with a regular succession, either of fine or of bad weather, for some months.

Lastly, an unproductive year mostly succeeds a rainy winter; as a rough and cold autumn prognosticates a severe winter. See also the article *BAROMETER*.

WEATHER is also applied to every thing lying to windward of a particular situation: hence a ship is said to have the weather-gage of another, when she is further to windward. Thus also, when a ship under sail presents either of her sides to the wind, it is then called the weather-side, and all the rigging, &c. situated thereon are distinguished by the same epithet, as, the weather shrouds, weather lifts, weather braces, weather bow, weather quarter, &c.

Table of the Weather, from Dr. Herschell's Observations.—The following table is from observations taken by the late Dr. Herschell, concerning the weather.

Time of New or Full Moon, or of entering the First Quarter	Weather likely to follow during the Quarter	
	In Summer.	In Winter
12 Noon, to 2 P.M.	Very Rainy,.....	Snow or Rain.
2 P.M. to 4 —	Changeable,.....	Fair and Mild.
4 — to 6 —	Fair,.....	Fair.
6 — to 10 —	{ Fair, if Wind N.W....	{ Fair, Frosty if
	{ Rain, if Wind S or S.W.	{ Wind N. or N.E.
		{ Rain or Snow, if
		{ Wind S. or S.W.
10 — to 12 Midnight.	Fair,.....	Fair and Frosty.
12 Midnight, to 2 A.M.	Fair,.....	{ Hard Frost unless
		{ Wind S. or W.
2 A.M. to 4 —	Cold, with Showers,...	Snow and Stormy.
4 — to 6 —	Rain,.....	Snow and Stormy.
6 — to 8 —	Wind and Rain,.....	Stormy.
8 — to 10 —	Changeable,.....	{ Cold, Rain if wind
		{ W., Snow if E.
10 — to 12 Noon,	Frequent Showers, ..	{ Cold, with high
		{ Winds.

WEATHER Beaten, an epithet applied to any thing which appears to have borne much hard or rough weather.

WEATHER Bit, a turn of the cable about the end of the wind-lase, outside of the knight-heads. It is used to check the cable, in order to slacken it gradually in tempestuous weather, or when the ship rides in a strong current.

WEATHER Boards, are pieces of plank placed in windows of a dwelling, or in the ports of a ship, when laid up in ordinary; they are in an inclined position, so as to turn off the rain without preventing the circulation of air.

110.

Composition for Preserving Weather Boarding.—Take three parts of air-slacked lime, two of wood ashes, and one of fine sand, or sea-coal ashes. Sift these through a fine sieve, and add as much linseed oil as will bring it to a consistence for working with a painter's brush; great care must be taken to mix it perfectly. Two coats are necessary, the first rather thin, the second as thick as can conveniently be worked.

WEATHER Cloths, long pieces of canvass or tarpauling, used to preserve the hammocks from injury by weather when stowed; also to defend persons from the wind and spray.

WEATHER Helm, a ship is said to carry a weather helm when she is inclined to come too near the wind, and therefore requires the helm to be kept constantly a little to windward.

WEATHER Rolls, those inclinations which a ship makes to windward in a heavy sea; those which she makes to leeward being termed lee-lurches.

WEATHER Glass. See *BAROMETER* and *HYGROMETER*.

WEATHER Shore, the shore which lies to windward of a ship.

WEATHER Tide, implies that which, by setting against a ship's lee-side, while under sail, forces her up to windward.

WEATHER-GLASSES, are instruments contrived to indicate the state or disposition of the atmosphere, and the various alterations in the weather: such are barometers, thermometers, hygrometers, &c.

WEAVERS. The wages of journeymen weavers in London are to be settled by the lord mayor, recorder, and aldermen. Masters giving more wages than is appointed, to forfeit 60*l.* and journeymen demanding, or combining to demand more, to forfeit 40*l.* or be imprisoned three months.

WEAVING. With the antiquity of weaving we are neither much acquainted, nor, however amusing such knowledge might be to the antiquarian, is this loss greatly to be regretted. That the art was brought to considerable perfection in very early ages, is sufficiently obvious both from sacred and profane history. There seems also little doubt that it is of Asiatic origin, and has only gradually extended to the western parts of Europe. We have the authority of Julius Cæsar, that, when he invaded Britain, it was totally unknown; and the many public acts relative to the woollen manufacture in the earlier period of English history, evidently prove that the greater part of our wool was, for a long series of years, exported in a raw state, and manufactured upon the continent. The cruelties and atrocities of the Duke of Alva, in 1587, and the subsequent persecutions attendant on the revocation of the edict of Nantz by Louis XIV. are assigned by historians as the causes which gave to Britain the knowledge and ingenuity of foreign artisans, and permanently founded the woollen and linen manufactures, the former of which has become the acknowledged staple of England, and the latter of Ireland. The much more recent invention of Sir Richard Arkwright has introduced the very extensive manufacture of cotton, and added a lucrative and elegant branch of traffic, the lighter and fanciful department of which has become, in some measure, the staple manufacture of Scotland; whilst the more substantial and durable have added to England a manufacture, inferior, in importance and extent, only to the woollen.

The process of manufacture of all these descriptions of cloth, from the raw to the finished or marketable state, may be divided into three great stages of manufacture.

1st. The preparatory processes which the raw material undergoes, to bring it into that state in which it is fit to assume the appearance of cloth, or what is generally understood by the term *yarn*. For the account of these operations, we must refer the reader to the respective articles *COTTON*, *FLAX*, *WOOL*, *SILK*, *LOOM*, &c.

2d. The operations by which the materials are brought from the state of yarn into that of cloth, which is properly the subject of this article, but which we can here only treat in a general way; for the different kinds are so numerous and varied, that we must refer much of the peculiarities to the articles which will be found under the respective titles or names, which various kinds of cloths or stuffs are known.

3d. The processes which the cloth undergoes, after it is out of the weaver's hands, to fit it for the market, and which must also refer to the various articles—*BLEACHING*, *PRINTING*, *CALICO*, *GLAZING*, and many others.

112 H

In general, we may remark, that the great requisites in every species of cloth, from the heaviest to the lightest fabrics, are durability, warmth, and beauty. For those kinds which compose the household furniture and dress of the generality of mankind, the first and second are the most essential; and for the ornamental kinds, which furnish show and splendour to the drapery of the opulent and luxurious, the latter is almost the only quality ever required.

Kendall's loom, which works exactly like the common Spitalfield's loom, with the same tyings, hangings, &c. has its principal action simply promoted by a single revolving bar mounted upon the top of the ordinary loom, equipped with four wipers, and two cams or snails. The two central wipers operating upon a lever, moving the batton as required; the two cams, right and left, acting alternately on a lever each, at the reverse end of which are connected two vertical rods, suspended from a bracket in front of the loom; also the two levers being connected by a spiral spring, that the action of the cams at the necessary periods causes the spring to become charged, as the lever in traversing the cam meets with a sudden declension or fall, causing the spring to operate and drive the shuttle across the work. The other two wipers act upon two treadles, to make the shed or opening for the passage of the shuttle. One revolution of this bar completes two shutes, causes these cams and wipers to act uniformly with each other, performing the whole operation required in simple weaving. The way to accomplish more complex weaving, when more than two treadles are required, is by introducing a second bar, equipped with as many wipers as treadles wanted, the wipers being placed at equal distances on the circle of the bar. If four is necessary, as the principal bar making one revolution acts upon the battons twice; therefore, in order to work over the four treadles upon the second bar, the principal bar in this case must revolve twice to the secondary one, and so on to any given number of treadles. If five treadles are required, the principal bar must revolve two and a half times to the secondary bar once, and so on to any other number, the two bars being regulated by equipping each with cog-wheels for that purpose. If a greater number of treadles are required more than this, or the hand-loom is able to accomplish with ease, it only requires the aid of the jackard mounted upon the loom, simplifying the complex figured weaving. This loom is effective and simple: a boy of 12 years of age, with a proper fly-wheel, would find no difficulty in turning six or eight of these looms. The number of looms one weaver is capable of working must depend on two principal objects,—the quality of the goods manufactured, and the quality of the material made use of, varying from two to five looms, such as persians, sarcenets, levantines, and poor satins, which, with good materials, require little attention. Rich works, with an able weaver and good materials, will be able to work two looms with an addition of some light work before mentioned. The work is, of course, better than that performed according to the old plan by hand; the machine acting more steadily, and operating with less of stickings.

Previous to entering into any details of other particulars, we shall lay before our readers such general remarks as occur upon what is termed the fabric of cloth, a matter which we conceive to be not only of the most essential importance, but which has been most unaccountably neglected, even by those who practise the manufacture, and who, with very few exceptions, regulate their operations in this respect by no fixed or determinate rule, but generally are contented merely to copy what they are taught, without any other guide to detect error than natural experience, which very frequently is dearly purchased. Yet we conceive it very possible, that this important point may be reduced to such a degree of mathematical precision, as might render it capable of conclusive demonstration, or at least that the approximation may be so near, as to guard the person who will be at pains to adopt it, from almost the slightest danger of great error, even in regulating the fabric of any species of cloth to which he has not been previously accustomed. For the better understanding of this method, it may be necessary to consider, very briefly, that quality of yarn which is called its *grist* or *fineness*.

If a thread of yarn be considered as a cylinder, its weight must be in the compound ratio of its magnitude and density.

Now, yarn being made up in hanks of a determinate length, this length may be considered as the altitude of the cylinder. If cylinders are in proportion to their circumscribing squares, the square root of the square will be equal to the diameter of the base. When yarn of any kind is warped, and stretched in a loom, to undergo the subsequent operation of being woven into cloth, the threads which compose the warp are parallel to each other, and their parallel situation is preserved by the utensil called the reed, through the intervals between the divisions of which a certain number of threads pass. The number of divisions in this reed, therefore, ascertains the number of threads of a warp which are to be woven into cloth of any determinate breadth. Now the breadth of every thread or cylinder being the diameter of its base, and the reed being the scale which regulates the number of these threads in a given measure, the ratio which the one bears to the other ascertains the number of threads, and their contiguity to each other in the cloth. Let then the square root of the mass in any determinate length of yarn be taken as the measure of the diameter of the base of a thread, and let the number of the reed which will form a proper fabric, be known, and any other will be found to form a similar fabric. From this arises a very simple analogy or proportion, which may be thus stated:—Let the weight of one kind of yarn be expressed by a , and that of another by b . Let a be properly woven in a reed or scale which contains 1200 intervals or divisions in 37 inches, which is the common measure of the linen reed. Then to ascertain the proper reed for b , the proportion will be as \sqrt{a} is to 1200, so is \sqrt{b} to the reed required. Hence, as a is to 144, so is b to the square of the reed required. Suppose now, that a represents cotton yarn No. 60, and b represents No. 100, then,

$$\text{as } 60 : 144 :: 100 : 14,400,$$

the root being 15.49 nearly, which is the answer. From this the following simple arithmetical proportion will arise for practical use.

1st. If the yarn is known, and the number of the reed wanted,

As the name or designation of the first yarn given

To the square of the given reed.

So is the name or designation of the second yarn

To the square of the reed required.

2d. If, as before, the yarn and reed are known, and the yarn wanted to fit any other reed.

As the square of the given reed,

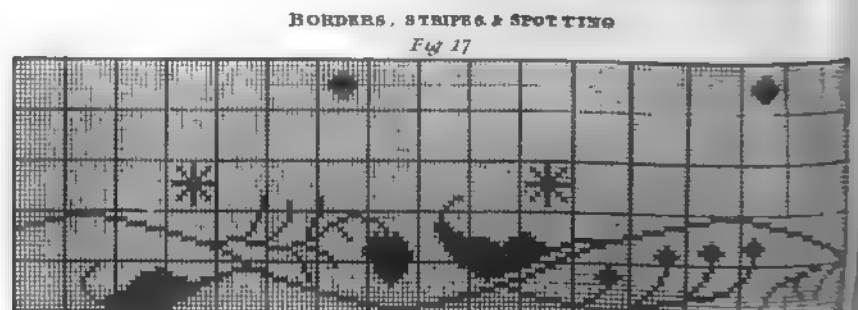

To the yarn,

So is the square of the other reed

To the yarn required.

In actual practice, the following objection, which is very plausible, will readily occur to practical manufacturers, and, at first sight, will probably induce almost the whole of them to reject these rules as erroneous and inconclusive. They will assert, and with truth, that a manufacturer who would implicitly adopt and follow these rules, would either make all his fine goods so dense and heavy in the fabric as to disgust his customers; or that his coarse goods would be so flimsy in the texture as to be totally useless. To this it is only necessary to reply, that it arises from no error in the calculation, nor want of truth in the general principle, but in what was premised as a general requisite in cloth at the outset, namely, that the durability and thickness is the first object in coarse goods, and beauty and transparency in fine. It would afford but a slender recommendation to a birth-day dress, to possess that warmth and durability which would form the chief excellence of a watch-coat or blanket; and it would be equally useless to give to the coarse manufacture, which is valuable in proportion to the shelter which it affords from the inclemency of wind and weather, qualities which could only afford gratification to the eye, by the sacrifice of every comfort.

The warp of a web being longitudinally stretched in parallel straight lines, and the warp or weft being inserted at right angles to it, the substance produced as cloth will bear a strong analogy to the form of a raft of wood, consisting of two platforms of square beams laid across each other, and fastened together; or if we suppose, that a number of cylindrical pieces of wood, such as the top masts or yards of a ship, are laid parallel to each other, and that cords or ropes are interwoven between them together, we shall have a very exact representa-

tion of a piece of cloth on a scale of such magnitude as will admit of all the proof of actual measurement. In cloth, even of the finest kinds, the length, breadth, and number of the component thread of cylinders, in the piece, may be ascertained with equal precision; but from the smallness of the diameter of every thread, it becomes impossible to measure them actually with any degree of accuracy. The length and the weight, or mass, however, being known, the diameter may be found by a calculation, which bears evident marks of great exactness, and we may then safely assume that no difference can arise, provided the densities of all threads are the same. Upon this point, however, there has been some difference of opinion, and the subject has been so little investigated in a scientific manner, that it would be perhaps presumptuous to draw any absolute conclusion upon it. We shall therefore only observe, that the argument upon which the increase of density in fine yarn above coarse chiefly rests, is this, that in spinning fine yarn, a greater number of revolutions of the wheel are necessary to give the twist sufficiently to produce a proper cohesion of the fibres than in coarse. This is incontrovertibly true; and as the filaments or fibres, by this twisting, assume the form of a screw or spiral, the point to be decided is, simply, whether by this excess of twisting, the fibres of fine yarn are not brought more closely into contact than those of coarse; and consequently, that the diameter of the thread is diminished in the same proportion that the twisting is increased.

It must be obvious, that where the circumference exposes a small surface, many more revolutions will be required than where it presents a large one, before all the fibres can be sufficiently stretched; and consequently, that fine yarn will always require more twisting than coarse, to give it the same tenacity. But as every thread, from the stoutest cable to the finest which human art and industry can produce, contracts in length by the operation of twisting, there seems reason enough to conclude, that the compressing power exerted, acts either entirely upon the length, or that what is exerted on the diameter, must bear a very small proportion indeed to the other; we may therefore infer, that the nearest approximation to actual truth, will be to consider a rope or thread like any other solid cylinder, and that the difference of density will not very materially affect the calculation. Upon this principle, we shall easily arrive at a very considerable degree of mathematical precision, and, upon the whole, come nearer to actual truth than by any other hypothesis yet known.

In the Plate (CLOTH MANUFACTURE) will be found some figures, explanatory of what further remarks may be necessary on this subject, as connected with the fabric; and it will also be useful in conveying correct ideas of the varieties of texture most generally used both in the substantial and flimsy descriptions of woven goods.

Principle of Texture.—Figure 1. This figure may be supposed to represent any solid body composed of various parts, lashed together. If the darkened squares are so many parallel beams of wood, connected by cordage, we arrive at once at a precise idea of texture. The length of these beams is known by measurement: the breadth of the whole consists of the aggregate number of pieces of wood, added to the space which the cords occupy between each, and which will be more or less in proportion to the thickness or diameter of these cords. It is also obvious, that it is impossible to bring the beams into actual contact; for were we to suppose, that the connecting or lashing cords were actually as fine as human hairs, they must still occupy some portion of space. The thickness, it is equally apparent, is that of one beam and one cord; but if we suppose the cords every where in actual contact, we may then also suppose that the thickness is that of the beam and two cords. Now, it is hardly possible to conceive, that in a flexible substance, such as those used in the fabrication of cloth, any means could be devised to bring every thread of woof into actual contact, so as to cover the warp both above and below. We may therefore very safely assume, as a general principle, that the geometrical thickness of cloth is the measure of the diameter of one thread of the warp, added to the measure of the diameter of one thread of the woof; and that when those measures are equal, the thickness of the cloth is, of course, double the diameter of one of the threads of which it is composed. Thus we have

the utmost thickness of fabric of which cloth is capable, and more than even the strongest canvass, with which we are acquainted, can possess. Indeed a fabric of this kind, were it even easily attainable, would be practically useless; for the immense increase of density would so completely take away every degree of pliancy and flexibility, that the fabric would be as unsuitable for any purpose to which cloth is properly applicable, as a fir plank or a sheet of copper.

Open Fabric.—Figure 2. This figure represents a section of cloth of an open fabric, when the round dots, which represent the warp, are placed at a considerable distance from each other. In this figure we see very evidently, that the geometrical thickness of cloth may be considered in the duplicate ratio of the one thread; for if we suppose the two parallel lines which bound the figure, to represent two boards used in the calender press, where the cloth is finished, and that they are to be pressed together by any mechanical power, we shall at once see that their effect must immediately flatten the threads, and divest them of their cylindrical form.

Close Fabric.—Figure 3. This figure represents a plain fabric of that description which approaches the most nearly to any idea we can form of the most dense or close contact of which yarn can be made susceptible. Here the warp is supposed to be so lightly stretched in the loom, as to retain entirely the parallel state without any curves or flexure whatever, and the whole therefore is necessarily given to the woof. This mode of weaving can never really exist; but if the warp be sufficiently strong to bear any light stretching, and the woof be spun very soft and flexible, something very near it may be produced. This way of making cloth is well fitted for those goods which require to give considerable warmth, but they are sometimes the means of very gross fraud and imposition; for if the warp is made of very slender threads, and the woof of slackly twisted cotton or woollen yarn, where the fibrils of the stuff being but slightly brought into contact, are rough and oozy, a great appearance of thickness and strength may be given to the eye, when the cloth is absolutely so flimsy, that it may be torn asunder as easily as a sheet of writing paper. Many frauds of this kind are practised. A very common one is in a kind of fanciful stuff, which used to be hawked about the streets of London, and most of the large towns of Britain, especially the sea ports, by a set of men habited like sailors. These stuffs were composed of very fine silk warp, and very slackly twisted cotton woof, perhaps eight or ten times coarser than the warp. The silk, of course, entirely disappeared, and the semblance of a very strong fabric of cotton was presented, and sold apparently cheap, under the pretence of being smuggled home in an East Indiaman. Strength, beauty, and cheapness, were thus apparently united, and the unwary purchaser, whilst enjoying the triple pleasure of having profitably expended his money, procured a desirable acquisition, and outwitted all the precautions which either the government or directors could take, found, to his infinite astonishment and vexation, upon the first application of the finger and thumb, that his purchase, which was generally extolled by the vender for being as tough as the mainsail of a seventy-four, proved as weak as a cobweb. The impostor generally added to the fraud, by pulling the cloth apparently with great force in that direction in which the coarse woof gave the resistance, but cautiously avoided even a touch against the warp, which would at once have detected the fraud.

Open Fabric.—Figure 4. This figure gives a representation of the position of a fabric of cloth in section, as it is in the loom before the warp has been closed upon the woof, which still appears as a straight line. This figure may usefully illustrate the direction and ratio of contraction which must unavoidably take place in every kind of cloth, in a greater or smaller degree, according to the density of the texture, the dimensions of the threads, and the description of the cloth. Let A B represent one thread of woof completely stretched by the velocity of the shuttle in passing between the threads of warp which are represented by the round dots 1, 2, 3, 4, 5, &c. and those distinguished by 8, 9, 10, &c. When these threads are closed by the operation of the heddies to form the intertexture, the first tendency will be to move in the direction 1 b, 2 b, &c. for those above, and in that of 8 a, 9 a, &c. for those below; but the contraction of A B, by its deviation from a straight to a curved line, in

consequence of the compression of the warp thread 1 *b*, 2 *b*, &c. and 1 *a*, 2 *a*, &c. in closing, will produce, by the action of the two powers at right angles to each other, the oblique or diagonal direction denoted by the lines 1, 8—2, 9 to the right, for the threads above; and that expressed by the lines 2, 8—3, 9, &c. to the left, for the threads below. Now, as the whole deviation is produced by the flexure of the thread A B, if A is supposed to be placed at the middle of the cloth, equidistant from the two extremities, or *selvages* as they are called by weavers, the thread at 1 may be supposed to move really in the direction 1 *b*, and all the others to approach to it in the direction represented, while those to the left would approach in the same ratio, but the line of approximation would be inverted. By pursuing this plan, which, as far the writer of this article knows, is totally new, the theory of fabric might be reduced to a very great degree of certainty; and here a field is entirely open for the researches of an expert geometrician to apply the principles of his science to the most extensive and useful manufacture, not only of this country, but of every other.

Figure 6 represents that common fabric used for lawns, muslins, and the middle kind of goods, the excellence of which neither consists in the greatest strength, nor in the greatest transparency. It is entirely a medium between fig. 2 and fig. 3. Its principles are in every respect similar to those already noticed.

In the efforts to give great strength and thickness to cloth, it will be obvious, that the common mode of weaving by constant intersection of warp and woof, although it may be perhaps the best which can be devised for the former, presents invincible obstructions to the latter beyond a certain limit. To remedy this, two modes of weaving are in common use, which, while they add to the power of compressing a great quantity of materials in a small compass, possess the additional advantage of affording much facility for adding ornament to the superficies of the fabric. The first of these is double cloth, or two webs woven together, and joined by the operation. This is chiefly used for carpets; and its geometrical principles are entirely the same as that of plain cloth, supposing two webs to be sewed together. A section of the cloth will be found in fig. 6; and what further relates to this part of the subject, in the article CARPET.

Of the simplest kind of twisted fabrics, a section is given in fig. 7; and as this is a most important branch of the cloth manufacture, it may be proper to consider it with some attention. The great and prominent advantage of the twisted fabric in point of texture, arises from the facility with which a very great quantity of materials may be put closely together. In the figures, the warp is represented by the dots in the same straight line as in the plain fabrics; but if we consider the direction and ratio of contraction, upon principles similar to those laid down in the explanation given of fig. 4, we shall readily discover the very different way in which the tweeling fabric is effected.

Thus we see by the figure, when the dotted lines are drawn at *a*, *b*, *c*, *d*, their direction of contraction, instead of being upon every second or alternate thread, the natural tendency would consequently be to bring the whole into the form represented by the lines and dotted circles at *a*, *b*, *c*, *d*. In point then of thickness, from the upper to the under superficies, it is evident that the whole fabric has increased in the ratio of nearly three to one. On the other hand it will appear, that the four threads or cylinders being thus put together in one solid mass, might be supposed only one thread, or like the strands of a rope before it is twisted; but, to remedy this, the thread being shifted every time, the whole forms a body in which much aggregate matter is compressed; but where, being less firmly united, the accession of strength acquired by the accumulation of materials, is partially contracted by the want of equal firmness of junction.

The second quality of the tweeled fabric, *susceptibility of receiving ornament*, arises from its capability of being inverted at pleasure, according to fig. 9. In this figure, we have, as before, four threads, and one alternately intersected; but here the four threads marked 1 and 2, are under the woof, while those marked 3 and 4 are above. As this in no way affects the solidity or strength of the texture, but is merely an auxiliary

aid for the addition of ornament, the further discussion of this property will be more appropriately introduced in that part of this article which relates to the ornamental principles of texture.

Figure 8. This figure represents that kind of tweeled work which produces an ornamental effect, and adds even to the strength of a fabric, in so far as accumulation of matter can be considered in that light. The figure represents a piece of velvet cut in section, and of that kind which, being woven upon a tweeled ground, is known by the name of Genoa velvet; a pretty strong presumption, that the origin of this manufacture at least, in Europe, is Italian. That part, however, which produces the ornament, cannot properly be deemed likely to add much to the strength of the fabric, in so far as this is effected by any attempt at divulsion; but when the impulse is by friction, it must contribute very materially to its preservation. Hence, in practical use, velvets of every kind are in great estimation, for three substantial reasons:—

1st. Because, by combining a great quantity of materials in a small compass, they afford great warmth. 2nd. From the great resistance which they oppose to external friction, they are very durable. And, 3rd. Because, from the very nature of the texture, they afford the finest means of rich ornamental decoration. The use of velvet cloths in cold weather, is a sufficient proof of the truth of the first. The manufacture of plush corduroy, and other stuffs, for the dress of those exposed to the accidents of laborious employment, evinces the second; and the ornamented velvets and Wilton carpeting, are demonstrative of the third of these positions..

In the figure, the diagonal form which both the warp and woof of cloth assume, is very apparent, from the smallness of the scale. Besides what this adds to the strength of the cloth, the plush part, which appears interwoven at the darkly shaded intervals 1, 2, 3, &c. forms, when finished, the whole covering or upper surface. The principle, in so far as regards texture, is entirely the same as any other tweeled fabric, and a more minute discussion must be referred to the particular article.

Corduroy.—Figure 10. This figure, which represents corduroy, or king's cord, is merely striped velvet. The principle is entirely the same; and the figure itself will sufficiently evince that the one is merely the copy of the other. The remaining figures in the plate represent those kinds of work which are of the most flimsy and open description of texture; those in which neither strength, warmth, nor durability, is much required, and of which openness and transparency are the chief recommendations. For these reasons, the nature and principle of the texture may be better understood by considering them as mere superficies, than by any section which could be exhibited. The two kinds of gauze and catgut, which form the basis of all the varieties, are still exhibited in section, and the two others, which may be varied almost to infinity, are shewn superficially.

Common Gauze.—Figure 11. This figure represents common gauze, or linan, a substance used for various purposes. The essential difference between this description of cloth and all others, consists in the warp being twined or twisted like a rope during the operation of weaving; and hence it bears a considerable analogy to the substance usually known by the name of lace. The twining of gauze is always open, flimsy, and transparent; but, from the twining of the warp, it possesses an uncommon degree of strength and tenacity, in proportion to the quantity of materials which it contains. This quality, together with the transparency of the fabric, renders it peculiarly adapted for ornamental purposes of various kinds, particularly for flowering or figuring, either in the loom, or by the needle.

In the warp of gauze there arises a much greater degree of contraction during the weaving than in any other species of cloth, and this is produced by the twining. The geometrical ratio of this contraction must evidently depend entirely upon the same principle which regulates the contraction of the yarn in spinning, and therefore it is unnecessary to add to what has been already stated upon that subject. By inspecting the figure, it will be apparent, that the twisting between every intersection of woof amounts precisely to one complete revolution of both threads; hence the following difference between this and every other species of weaving, namely, that the same

race horses, and afterwards applied to the more reputable service of weighing loaded carriages.

The annexed figure is a plan of the machine; K L M N is the plan of a rectangular box, which has a platform lid or cover of size sufficient for placing the wheels of a cart or waggon. The box is about a foot deep, and is sunk into the ground till the platform cover is even with the surface. In the middle of the box is an iron lever supported on the fulcrum pin h , formed like the nail of a balance, which rests with its edge on arches of hardened steel firmly fastened to the bottom of the box. This lever goes through one side of the box, and is furnished at its extremity with a hard steel pin l , also formed

Fig. 5.

to an edge below. In the very middle of the box it is crossed by a third nail of hardened steel g , also formed to an edge, but on the upper side. The three edges are in one horizontal plane, as in a well-made balance. In the four corners, A, A', E, E', of the box are firmly fixed four blocks of tempered steel, having their upper surfaces formed into spherical cavities, well polished and hard tempered. A B C D E represents the upper edge of an iron bar of considerable strength, which rests on the cavities of the steel-blocks in A and E, by means of two hard steel studs projecting from its under edge, and formed into obtuse-angled points or cones. These points are in a straight line parallel to the side K N of the box. The middle part C of this crooked bar is faced with hard tempered steel below, and is there formed into an edge parallel to A E and K N, by which it rests on the upper edge of the steel pin g , which is in the lever. In a line parallel to A E, and on the upper side of the crooked bar A C E, are fixed two studs or points of hardened steel B and D projecting upwards above half an inch. The platform cover has four short feet like a stool terminated by hard steel studs, which are shaped into spherical cavities and well polished. With these it rests on the four steel points B, B', D', D. The bar A C E, is kneed in such a manner vertically, that the points A, B, D, E, and the edge C, are all in a horizontal plane. These particulars will be better understood by looking at the elevation in fig. 6. What has been said of the bar A C E must be understood as also said of the bar A' C' E'.

Draw through the centre of the box the line $a b c$ perpendicular to the line A E, B D. It is evident that the bar A C E is equivalent to the lever $a b c$, having the fulcrum or axis A E resting with its extremity C on the pin h , and loaded at b . It is also evident that $a c$ is to $a b$ as the load on this lever to the pressure which it exerts on the pin g , and that the same proportion subsists between the whole load on the platform, and the pressure which it exerts on the pin g . It will also appear on an attentive consideration, that this proportion is no wise deranged in whatever manner the load is placed on the platform. If very unequally, the two ends of the pin g , may be unequally pressed, and the lever wrenched and strained a little; but the total pressure is not changed. If there be now placed a balance or steel yard L K, in such a manner that one end of it may be directly above the pin l in the end of the lever E O F they may be connected by a wire or slender rod, and a weight on the other arm of the balance or steel-yard may be put in

equilibrium with any load that can be laid on the platform. A small counterpoise being first hung on to balance the apparatus when unloaded, any additional weight will measure the load really laid on the platform. If $a b$ be to $a c$ as 1 to 8, and E O to E F also as 1 to 8, and if a common balance be used above, 64 pounds on the platform will be balanced by one pound in the scale, and every pound will be balanced by one-fourth of an ounce. This would be a very convenient partition for most purposes, as it would enable us to use a common balance and common weights to complete the machine; or it may be made with a balance of unequal arms, or with a steel yard.

Some have thought to improve this instrument by using edges like those of the nails of a balance instead of points. But unless made with uncommon accuracy, they will render the balance very dull. The small deviation of the two edges A and E, or of B and D, from perfect parallelism to K N, is equivalent to a broad surface equal to the whole deviation. We imagine, that with no extraordinary care, the machine may be made to weigh within $\frac{1}{1000}$ of the truth, which is exact enough for any purpose in commerce.

It is necessary that the points be attached to the bars. Some have put the points at A and E in the blocks of steel fastened to the bottom, because the cavity there lodged water or dirt, which soon destroyed the instrument with rust. But this occasions a change of proportion in the first lever by any shifting of the crooked bars; and this will frequently happen when the wheels of a loaded cart are pushed on the platform. The cavity in the steel stud should have a little rim round it, and it should be kept full of oil. In a nice machine a quarter of an inch of quicksilver would effectually prevent all these inconveniences. The simplest and most economical form of this machine is to have no balance or second steel-yard; but to make the first steel-yard E O F a lever of the first kind, viz. having the fulcrum between O and F, and allow it to project far beyond the box. The long or outward arm of this lever is then divided into a scale of weights commencing at the side of the box. A counterpoise must be chosen, such as will, when at the beginning of the scale, balance the smallest load that will probably be examined. It will be convenient to carry on this scale by means of eke-weights hung on at the extremity of the lever, and to use but one moveable weight. By this method the divisions of the scale will have always one value. The best arrangement is as follows: place the mark 0 at the beginning of the scale, and let it extend only to 100, if for pounds, or to 112 if for cwt.; or to 10 if for stones; and let the eke-weights be numbered 1, 2, 3, &c. Let the lowest weight be marked on the beam. This is always to be added to the weight shewn by the operation. Let the eke-weights stand at the end of the beam, and let the general counterpoise always hang at 0. When the cart is put on the platform, the end of the beam tilts up. Hang on the heaviest eke-weight that is not sufficient to press it down. Now complete the balance by sliding out the counterpoise. Suppose the constant load to be 312 lbs. that the counterpoise stands at 86, and that the eke-weight is 9; we have the load = $966 + 312 = 1298$ lbs.

WEIGHT, gravity, in Physics, a quality in natural bodies, whereby they tend downwards towards the centre of the earth.

WEIGHT, pondus, in Mechanics, is any thing to be raised, sustained, or moved by a machine, any thing that in any manner resists the motion to be produced.

WEIGHT, in Commerce, denotes a body of a known weight, appointed to be put in the balance against other bodies, whose weight is required.

WEIGHTS, Modern, English. See MEASURES.

WEIGHTS, and Measures. The standard of measures were originally kept at Winchester, which measure was, by the law of king Edgar, ordained to be observed through the kingdom.

WELD, or **WOALD**, (*reseda luteola*, Linn.) is a plant cultivated in Kent, Herefordshire, and many other parts of this kingdom. The whole of the plant is used for dyeing yellow; though some assert that the seeds only afford the colouring matter. Two sorts of weld are distinguished: the bastard or wild, which grows naturally in the fields; and the cultivated, the stalks of which are smaller, and not so high. For dyeing, the latter is preferred, it abounding more in colouring matter. The more slender the stalk, the more it is valued. When the weld is ripe

frame then being a parallelogram, and the centre being fixed, the two joints which are diagonally opposite, will, in all their motions, be similar; therefore, if a straight guide were affixed to the carriage near the top of the parallelogram, and four small rollers were attached to the joints *V u, w, y*, so that they bore on the top of this straight piece, then would the scaper be properly guided when on level ground. And if another straight piece were placed above this, forming a groove with the lower piece, the little wheels would bear upwards against it when the feet came upon an elevation or depression of ground, and it would for a time guide the motion instead of the lower piece. Or these straight guides might be fixed *below*, so as to conduct the wheels in the lower part of their circuit. But the following and better way of guiding has been adopted by the inventor in his models, as possessing less friction:—

It is to be observed, that when the top and bottom joints *V* and *w*, fig. 2, describe right lines on the carriage, as it moves along, the intermediate joints *u* and *v*, describe curves relative to the carriage, very nearly resembling parts of circles (on both sides) drawn through the three centres of the joints *u* and *w*, fig. 1 of the plate, when the parallelogram is square, and through the joint between them, where the joints reach when fully extended, (as in fig. 2); and a similar observation applies to the other side *y V*. The diagram, fig. 9, contains this circle and the true curve shewn together, with the difference that exists between them, the true curve being numbered from 1 to 16, and small circles drawn to shew the axle as it goes. It is obvious, that if the joints, which are not on the ground, be by any means guided in this curve, then will the top and bottom joints also be properly guided; and it is by conducting these intermediate joints, that the motion is governed, with less friction than by the curve itself. Because as the curve differs but little from a circle, the means exist of attaching a radius or arm to the centre of each joint, (so that it can turn round,) reaching nearly to the centre of the circle, which the curve resembles, and to place a much smaller curve partly round it, of such figure, that when the arms are by any means caused to point to the centre of the circle in fig. 23, which also represents the centre of the large circle in fig. 9, while a pin in the end of the arms properly traverses this curve, then the joint to which it is attached will be guided in the true curve, 1, 3, 15, 16, &c. in the same way as if it were guided by the curve itself, though with much less friction. But this little curve alone will not restrain the arm in a line with the centre, and the following method has therefore been adopted.

The four arms *S O, J K, L H*, and *N P*, figs. 15, 16, and 18, have two pins or rollers at the end of each of them, (not opposite, but reversed,) which guide the motion. One of these pins is on one side of the arm, and one on the other, in contrary directions, and at a small distance from each other, as shewn, and they work round two similarly curved guides, 1, 2, 3, 4, figs. 1, 2, and 9, fixed in the carriage, but whose curvature is also reversed. One of these guides in the plate hides the other, and which is itself put out of sight by its own back, but both are dotted to shew them; and they are fixed to the carriage, the two facing each other, (as a box faces its lid,) leaving a space between them for the arms, which work between the two, one of the pins or rollers of the arms working in the one curve, and one in the other, each bearing half the pressure.

Especial care must be taken not to fix the pins on the wrong side of the arms, or the curves with the wrong faces to the carriage and parallelogram. Thus in fig. 18, the pins suit, supposing the guide, of which the back is seen in fig. 2, to be next to the parallelogram, or when faced, as in the plate, and in fig. 17, they would suit, if the back of the one now seen were nearest to the body, as shewn in the diagram, fig. 9, but the pins being still reversed to each other, the position of the curves not being altered by changing or turning them, or by fixing them end for end. The curves must always be reversed to each other, and there are two ways of reversing them, one answering to arms made as in fig. 18, and the other as in fig. 17. These two rollers then keep each other in their proper position while they work round the small ends of the guide, and during which period they give the proper extension to the feet, thus acting instead of a rail-way. The long part, *I*, of the guides serves only to conduct the arms to the bearing ends, but

scarcely suffers any pressure or friction there. The dark curve in the diagram, fig. 9, is so placed as to answer to the arm *17*. The light shaded pin works in the dark curve, and the dark pin in the light curve.

Though the ends of the guides conduct the arms, it is found necessary to cut off a small portion of these ends where the arms enter, and leave these places; which otherwise would contain asperities injurious to the motion. (See Repertory for June 1821.) Though by such means the scaper loses its guidance for a short space, but to supply its place there are affixed to the upper guide two small curves *e, i, f*, and *g, j, k*, fig. 11; and there are attached to the parallelogram four small rollers, *a, b, c, d*, which at times bear against the outside of *e, i, f*, and against the inside of *g, j, k*; the defect being thus remedied. But the rollers only bear against a small part of these curves, excepting on very unlevel ground, and in that case they keep the parallelogram properly extended, (see the sequel.)

While the arms traverse the long part of the guides, they go inclined, as *W n*, and *D q*, fig. 11; when to prevent their becoming, by any accident, perpendicular, and striking the axle *L*, the lower guide, (but not the upper one,) is furnished with an inside projection *m, n, p, q*, forming a groove with the guide itself, (but found to require more width near the corners than in any other place,) and in this groove one of the rollers of the arms works, thus keeping the arm properly inclined, and in the same direction, whether the carriage goes from right to left, or left to right. Or the upper guide, instead of the lower, may have such a projection, and then the arms will traverse in the direction shewn in figs. 2 and 9. But as this inside projection will not serve when the parallelogram is nearly square, two small pins, *O* and *H*, fig. 11, are affixed between the upper guide and the curves *g, j, k*, and *e, i, f*, which by bearing loosely against a small projection upon each of the arms near *P H K* and *O*, keep the arms by that means right; these small projections having the peculiar and required property of causing the arms to enter the end portions of the guides in one position, and leaving them in another. Though only one guide must have the inside projection *m, n, p, q*, a small piece in the other, near *m* and *p*, is also serviceable in preventing the foot from being pushed back when fully extended, as *A, C*, fig. 2. In fig. 11, the outside plain line is the exterior of the top guide: the next plain line is the interior; the outside dotted line is the interior of the lower guide; and the inside dotted line is the inside projection. Fig. 10 is an end view of the scaper, the same letters referring to the same parts, and fig. 24 is one of the guides divided into lines of proper lengths, to express its shape.

In fig. 2 the scaper is shewn, supposing it jointed with common round axil, and boxes, but in fig. 1 the pins *v*, to avoid friction, are so contrived as to roll round within their boxes *G h*, upon a rounded angular side *k*, where the chief pressure exists, leaving the other two angular sides of the pins to slide, the insides of the boxes then being properly curved, keep the whole steady in its motion. Figs. 12 and 13 are the arms made after the same plan, and in fig. 14 *N n* is a front view of the pins upon the sides of the parallelogram. In order for the carriage to turn, the front scapers may be made to swing on common wheels; but it is far preferable for each front scaper to swing separately on a perpendicular axis immediately above itself, and then, as great steadiness is required, the guide of the front and back scaper should be connected by two circular pieces sliding within each other, shewn in fig. 21. *n, n, 8 y, t*, fig. 20, is a section of the guides, arms, and rollers, which are here suggested, in a peculiar form, to defend themselves from mud.

The last species of scaper we have to describe is shewn in figs. 5, 6, and 7. Fig. 7 being a kite view of fig. 5, the top rail of the carriage being removed. This sort of scaper is inferior to the last in point of friction; it is also rather less equable and quiet in its motion, and does not allow so much facility to the carriage in turning, but is of great strength, and better surmounts large obstacles when the feet happen to come upon them. It is also more calculated for uneven roads, owing to a peculiar property of changing its form and action according to the ground, so as to surmount those asperities which it does not escape, gradually, and effecting this in every instance while the carriage moves the length of a whole side of the parallelogram, instead of a small portion, as in the other species. It

segments of circles near the circle 1, 9, 16, so that each segment gets intersected by one of the same number from the opposite side; and these intersections, numbered in the figure, to shew from whence they originate, will also point out the curve sought for; from which proceed to find the small end curves, according to the following plan:—

Into one end of a flat ruler, the full length of the radius of circle 1, 9, 16, fix the point of a needle answering to the centre of the arm, and near the other end fix two needle points, situate like the centres of the pins of the arms, and between them out a groove pointing to the one needle point, which groove is to be caused to work and to slide on another needle, fixed in the centre of circle 1, 9, 16, while the single needle point is guided continually by the large curve near circle 1, 9, 16, and then will the two needle points trace out two small curves; round the boundary of each of which, must then be drawn a number of small circles, the size of the pins or rollers, so that the insides of them will shew the true shape of the ends of the curves. Instead of the ruler with points, &c. a piece of transparent horn with holes may be found convenient.

The shape of that part of the curve which connects the two end portions together, is of no decided figure, but still requires great exactness, and is found by repeated trials; which being done, two solid curves are fitted to the figures of the whole guides, reversedly screwed together, and this serves for a model or core on which to make and affix the guides themselves; taking care that the guides be fixed exactly horizontally; and for which purpose, draw a line from 9 to 9, fig. 9, horizontally, (supposing the figure in its natural position,) marking the double guide into two equal and similar portions. This then must be fixed, so that the two halves into which the line cuts the curve, be similarly situate to the two sides of the figure of the diagram, the centre, I, being in the middle.

The shape of the curves *g, j, k*, and *e, i, f*, fig. 11, is easily found by causing the feet to move in a right line, and observing the trace of the rollers on a board properly fixed, during the short time when the arms become useless, and also whilst the feet are approaching or leaving the level line of the ground; which part of the curves the rollers *a a, c b*, will bear against as they pass when the ground is unlevel, the feet being by this means kept in their proper course.

The curve *ZZZ*, figs. 5 and 6, is found at pleasure, so as to give an easy motion to the feet, in approaching and leaving the ground; and owing to the circular motion of the lever *VS* the two halves, *ZZ* and *Z*, will differ. But this curve, while it bears up the feet, tends also to raise the parallelogram, the sides of which are therefore very slightly curved, to prevent this evil from taking place; and the curvature is found, by causing the feet to move in a right line, observing the shape described by the flat face of the wheel *R* on the sides of the parallelogram.

In the diagram, fig. 9, the feet are shewn dotted, of a better shape than those in figs. 1 and 2, which construction prevents their suddenly falling off by any obstacle.

Fig. 26, is a screw for the nuts, or for other purposes, in which the side of the thread bearing the pressure is perpendicular, and the other side doubly inclined, thus uniting the strength of an angular thread to the advantage of a flat thread, viz. of preventing the nuts from bursting.

WHERRY, a name given to several kinds of light boats used on the sea-coast and up rivers. *Wherry* is also applied to some decked vessels used in fishing, in different parts of Great Britain and Ireland.

WHIP, among Sailors, a sort of small tackle, formed by the communication of a rope with a single immoveable block, or with two blocks, one of which is fixed and the other moveable; used to hoist up light bodies, such as empty casks, &c.

WHIP, or *Whip Staff*, is a piece of timber in form of a strong staff, fastened into the helm for the steersman, in small ships, to hold in his hand, in order to move the rudder, and direct the ship.

WHIRLING TABLE, a machine intended to represent the several phenomena in philosophy and nature, as the principal laws of gravitation, and of the planetary motions.

WHIRLPOOL, an eddy, vortex, or gulf, where the water is continually turning round. In rivers these are very com-

mon from various accidents, and are usually very trivial and of little consequence. In the sea they are more rare, but more dangerous. Sibbald has related the effects of a very remarkable marine whirlpool among the Orcades, which would prove very dangerous to strangers, though it is of no consequence to the people who are used to it. This is not fixed to any particular place, but appears in various parts of the limits of the sea, among those islands. Wherever it appears, it is very furious, and boats, &c. would instantly be drawn in and perish thereby, but the people who navigate them are prepared for it, and always carry an empty vessel, a log of wood, or a large bundle of straw, or some such thing, in the boat with them; and as soon as they perceive the whirlpool, they toss the article within its vortex, and thus keep themselves out of it. This substance, whatever it be, is immediately received into the centre and carried under water; and as soon as this is done, the surface of the place where the whirlpool was, becomes smooth, and they row over it with safety, and in about an hour they see the vortex begin again in some other place, usually about a mile distant from the other.

WHIRLS, small hooks fastened into cylindrical pieces of wood, which communicate by means of a leather strap with a spoke-wheel, whereby three of them are set in motion at once; they are used for the spinning of yarn for ropes.

WHIRLWIND, is a wind that rises suddenly, and is exceeding rapid and impetuous when risen, but soon spent. There are divers sorts of whirlwinds distinguished by their peculiar names, and the Prester, Typho, Turbo, Exhydia, and Ecnephias. The prester is a violent wind, breaking forth with flashes of lightning. This is rarely observed, and scarce ever without the ecnephias. Seneca says it is a typho, or turbo rekindled, or ignited in the air. A typho or vortex, most properly called whirlwind, or hurricane, is an impetuous wind, turning rapidly every way, and sweeping all round the place. It usually descends from on high, and is frequent in the eastern ocean, chiefly about Siam, China, &c. which renders the navigation of those parts very dangerous. The exhydia is a wind bursting out of a cloud with a great quantity of water. This only seems to differ in degree from the ecnephias which is frequently attended with showers. The ecnephias is a sudden and impetuous wind breaking out of some cloud, frequent in the Ethiopic sea, particularly about the Cape of Good Hope, and is generally called by seamen a travado.

Dr. Franklin, in his physical and meteorological observations, supposed a water-spout and a whirlwind to proceed from the same cause, their only difference being, that the latter passes over the land, and the former over the water. This opinion is corroborated by M. de la Pryme, in the Philosophical Transactions, where he describes two spouts observed at different times in Yorkshire, whose appearances in the air were exactly like those of the spouts at sea, and their effects the same as those of real whirlwinds. Whirlwinds have generally a progressive as well as a circular motion; so had what is called the spout at Topsham, described in the Philosophical Transactions; and this also by its effects appears to have been a real whirlwind. Water-spouts have also a progressive motion, which is more or less rapid, being in some violent, and in others barely perceptible. Whirlwinds generally rise after calms and great heats; the same is observed of water-spouts, which are therefore most frequent in warm latitudes. The wind blows every way from a large surrounding space to a whirlwind. Three vessels, employed in the whale fishery, happening to be becalmed, lay in sight of each other at about a league distance, and in the form of a triangle. After some time a water-spout appeared near the middle of the triangle, when a brisk gale arose, and every vessel made sail. It then appeared to them all, by the trimming of their sails, and the course of each vessel, that the spout was to leeward of every one of them; and this observation was further confirmed by the comparing of accounts, when the different observers afterwards conferred about the subject. Hence whirlwinds and water-spouts agree in this particular likewise. But if the same meteor which appears a water-spout at sea, should in its progressive motion encounter and pass over land, and there produce all the phenomena and effects of a whirlwind, it would afford a stronger conviction that a whirlwind and a water-spout are the same

water could very soon after be perceived to fly up along the middle of this canal like smoke in a chimney."

When Dr. Stuart's spouts were full charged, that is, when the whirling pipe of air was filled with quantities of drops and vapour torn off from the column, the whole was rendered so dark that it could not be seen through, nor the spiral ascending motion be discovered; but when the quantity ascending lessened, the pipe became more transparent, and the ascending motion visible. The spiral motion of the vapours, whose lines intersect each other on the nearest and farthest side of this transparent part, appeared therefore to Dr. Stuart like smoke ascending in a chimney; for the quantity being still too great in the line of sight through the sides of the tube, the motion could not be discovered there, and so they represented the solid sides of the chimney.

Dr. Franklin concludes, by supposing a whirlwind or spout to be stationary, when the concurring winds are equal; but if unequal, the whirl acquires a progressive motion in the direction of the strongest pressure. When the wind that communicates this progression becomes stronger above than below, or below than above, the spout will be bent or inclined. Hence the horizontal process and obliquity of water-spouts are derived.

WHIRLING TABLE, a machine intended to represent the several phenomena in philosophy and nature,—as, the principal laws of gravitation, and of the planetary motions.

WHISPERING-PLACES, depend upon this principle: if the vibrations of the tremulous body are propagated through a long tube, they will be continually reverberated from the sides of the tube into its axis, and by that means prevented from spreading till they get out of it; whereby they will be exceedingly increased, and the sound rendered much louder than it would otherwise be.

WHIST, a well-known game at cards, which requires great attention and silence; hence the name.

WHISTON, WILLIAM, an ingenious English mathematician and divine, was born in 1687, and died in 1752, upwards of 64 years of age. He was author of numerous works on philosophy and religion; of the former, his *Theory of the Earth*, and his *Astronomical Lectures*, are the only ones which it is necessary to enumerate in this place.

WHITEHURST, JOHN, an ingenious English mechanic and philosopher, was born in the county of Chester in 1713, and died in 1788, in the 75th year of his age.

WHOODINGS, those ends of planks which are let into the rabbets of the stem, the stern-posts, &c.

WIDOW, a woman who has lost her husband by death. In London, and throughout the province of York, the widow of a freeman is by custom entitled to her apparel, and the furniture of the bed-chamber called the widow's chamber.

WIFE. See **HUSBAND** and **WIFE**.

WILD (A) ROADSTAD, implies one that is open, or exposed to the wind and sea.

WILDERNESS, in Gardening, a kind of grove of large trees, in a spacious garden, in which the walks are commonly made either to intersect each other in angles, or have the appearance of meanders and labyrinths.

WILDFIRE, a kind of artificial or factitious fire, which burns even under water, and that with greater violence than out of it. It is composed of sulphur, naphtha, pitch, gum, and bitumen, and is only extinguishable by vinegar mixed with sand and urine, or by covering it with raw hides. Its motion or tendency is said to be contrary to that of natural fire, and it always follows the direction in which it is thrown, whether it be downwards, sideways, or otherwise. Several are of opinion that the ancient Greeks and Romans used this wildfire in their engagements at sea; whether or not that was the case, it was applied against the Saracens in a sea-fight, commanded by Constantine Pogonates, in the Hellespont, and with such effect, that he burnt the whole fleet therewith, wherein there were thirty thousand men. Constantine's successors used it on divers occasions, and with equal advantage; and what is very remarkable, they were so happy as to keep the secret of the composition to themselves, so that no other nation knew it in 980.

WILL AND TESTAMENT, is that disposition of property which is made by a person to take place after his decease. Every person capable of binding himself by contract, is

capable of making a will. Also a male infant of the age of fourteen years and upwards, and a female of twelve years or upwards, are capable of making a will respecting personal estates only. But a married woman cannot make a will, unless a power be reserved in the marriage settlement; but whenever personal property is given to a married woman, for her sole and separate use, she may dispose of it by will. If a femme sole make her will, and afterwards marry, such marriage is a legal revocation of the will. Wills are of two kinds, written and verbal; the former is most usual and secure. It is not absolutely necessary that a will should be witnessed; and a testament of chattels written in the testator's own hand, though it have neither the testator's name nor seal to it, nor witnesses present at his publication, will be good, provided sufficient proof can be had that it is his hand-writing. By statute 29 Charles II. c. 3, all devises of lands and tenements shall not only be in writing, but shall also be signed by the party so devising the same, or by some other person in his presence, and by his express direction, and shall be witnessed and subscribed in the presence of the person devising, by three or four credible witnesses, or else the testament will be entirely void, and the land will descend to the heir at law. A will even if made beyond sea, bequeathing land in England, must be attested by three witnesses. A will, however, devising copyhold land does not require to be witnessed; it is sufficient to declare the uses of a surrender of such copyhold land made to the use of the will. The party to whom the land is given becomes entitled to it by means of the surrender, and not by the will.—A *Codicil* is a supplement to a will, or an addition made by the person making the same, annexed to, and to be taken as part of, the will itself, being for its explanation or alteration, to add something to, or take something from, the former disposition, and which may also be either written or verbal, under the same restrictions as regards wills. If two wills are found, and it does not appear which was the former or latter, both will be void; but if two codicils are found, and it cannot be ascertained which was the first, but the same thing is devised to two persons, both ought to divide; but where either wills or codicils have date, the latter is considered as valid, and revokes the former.

WILLOWS, WREN'S Brake for Barking. The annexed drawing represents a newly invented brake for taking the bark off willows. The object of it is to prevent their being split, as they so often are, in the stripping, on account of the squeezing with the hand. The hand is not to be applied at all in using these brakes, springs being substituted, which do the work better, and a great deal more expeditiously.

Explanation of the Drawing.—A A is the frame, made of half-inch round iron, about two inches apart, or closer; B B, brake-irons to loosen the rind, 11 inches long; C C, screws to adjust the brake irons, according to the size of the rods to be stripped. The wider they are apart on the top, the stiffer they will work at the bottom; D D, springs, fixed on with screws at E E; F, a bar or guide, projecting an inch to prevent the rod from running down, which, when in use, must be the farthest part of the machine from the operator, and down on it the rod must come when worked; G, a key to keep the brake in its place when erected for use, by passing the end through two staples on a strong stake, provided for the purpose; H to I, fifteen inches; H to K, twenty-one inches, the whole length. The operator is to place himself in a position so as to have a sway of the body, with the left hand on the rod, to bring it down on the guide, by which the brake will be kept clean from the rind, &c. without further trouble. The chief point in making these brakes is, to make sure of the strength and elasticity of the springs.

WINCH, a cylindrical piece of timber, having an axis, when

extremities rest in two channels placed horizontally or perpendicularly, and furnished with clicks or pauls. It is turned about by means of a handle resembling that of a grindstone, and is generally employed as a purchase, by which a rope or tackle-fall may be more powerfully applied to any object than when used singly, or without the assistance of mechanical powers.

WIND, is also the name of certain long iron handles by which the chain-pumps are worked.

WIND, a sensible current in the atmosphere. The motions of the atmosphere are subject in some degree to the same laws as those of the denser fluids; if we remove a portion of water in a large reservoir, we see the surrounding water flow in to restore the equilibrium; and if we impel in any direction a certain portion, an equal quantity moves in a contrary direction, from the same cause; or if a portion, being rarefied by heat or condensed by cold, ascends in the one instance and descends in the other, a counter-current is the visible and natural result; and similar effects are found to follow the same causes in the atmospheric fluid. Thus, no wind can blow without a counter or opposite current, nor can any wind arise, without a previous derangement of the general equilibrium; the general causes of which may be stated as follows:

1. The ascent of the air over certain tracts heated by the sun. 2. Evaporation causing an actual increase in the volume of the atmosphere. 3. Rain, snow, &c. causing an actual decrease in its volume by the destruction of the vapour. Currents thus produced may be permanent and general, extending over a large portion of the globe: periodical, as in the Indian ocean; or variable, and as it were occasional, or at least uncertain, as the winds in temperate climates. General or permanent winds blow always nearly in the same direction. In the Atlantic and Pacific oceans, under the equator, the wind is almost always easterly; it blows, indeed, in this direction on both sides of the equator to the latitude of 28° . More to the northward of the equator, the wind generally blows between the north and east; and the farther north we proceed, we find the wind to blow to a more northern direction; more to the southward of the equator, it blows between the south and east; and the farther to the south, the more it comes in that direction. Between the parallels of 28° and 40° south latitude, in that tract which extends from 30° west to 100° east longitude from London, the wind is variable, but it most frequently blows from between the N.W. and S.W. so that the outward bound East-India ships generally run down their easting on the parallel of 36° south. Navigators have given the appellation of trade-winds to these general winds.

Periodical Winds.—Those winds which blow in a certain direction for a time, and at certain stated seasons change, and blow for an equal space of time from the opposite point of the compass, are called monsoons. During the months of April, May, June, July, August, and September, the wind blows from southward over the whole length of the Indian ocean, viz. between the parallels of 28° N. and 28° S. latitude, and between the eastern coast of Africa and the meridian which passes through the western part of Japan; but in the other months, October, November, December, January, February, and March, the winds in all the northern parts of the Indian ocean shift round, and blow directly contrary to the course they held in the former six months. For some days before and after the change, there are calms, variable winds, and tremendous storms with thunder, &c.

Causes of the WIND.—Philosophers differ in their opinions respecting the cause of these periodical winds; but a more probable theory of the general trade-winds is, that they are occasioned by the heat of the sun in the regions about the equator, where the air is heated to a greater degree, and consequently rarefied more, than in the more northern parts of the globe. From this expansion of the air in these tropical regions, the denser air in higher latitudes rushes violently towards the equator from both sides of the globe. By this conflux of the denser air, without any other circumstances intervening, a direct northerly wind would be produced in the northern tropic, and a southern one in the other tropic; but as the earth's diurnal motion varies the direct influence of the sun over the surface of the earth, and as by that motion this influence is communicated from east to west, an easterly wind would be

produced if this influence alone prevailed. On account of the co-operation of these two causes at the same time, the trade-winds blow naturally from the N. E. on the north, and from the S. E. on the south of the line, throughout the whole year; but as the sun approaches nearer the tropic of Cancer in our summer season, the point towards which these winds are directed will not be invariably the same, but they will incline more towards the north in that season, and more towards the south in our winter.

The land and sea breezes in the tropical climates may be considered as partial interruptions of the general trade-winds; and the cause of these it is not very difficult to explain. From water being a better conductor of heat than earth, the water is always of a more even temperature. During the day, therefore, the land becomes considerably heated, the air rarefied, and consequently in the afternoon a breeze sets in from the sea, which is less heated at that time than the land. On the other hand, during the night the earth loses its surplus heat, while the sea continues more even in its temperature. Towards morning, therefore, a breeze regularly proceeds from the land towards the ocean, where the air is warmer, and consequently more rarefied, than on shore.

The cause of the monsoons is not so well understood as that of the general trade-winds; but what has been just remarked suggests, at least, a probable theory on the subject. It is well known, that at the equator the changes of heat and cold are occasioned by the diurnal motion of the earth, and that the difference between the heat of the day and the night is almost all that is perceived in those tropical regions; whereas in the polar regions the great vicissitudes of heat and cold are occasioned by the annual motion of the globe, which produces the sensible changes of winter and summer; consequently, if the heat of the sun was the only cause of the variation of the winds, the changes, if any, that would be produced by those means in equatorial regions, ought to be diurnal only, but the changes about the pole should be experienced only once in six months. As the effects arising from the heat of the sun upon the air must be greater at the equator than at the poles, the changes of the wind arising from the expansion of the air by the sun's rays must be more steady in equatorial than in polar regions. The incontrovertible evidence of navigators proves this truth, that winds are more variable towards the poles, and more constant towards the equator. But in summer, the continual heat, even in high latitudes, comes to be sensibly felt, and produces changes on the wind, which are distinctly perceptible. In our own cold region the effects of the sun on the wind are felt during the summer months; for while the weather in that season of the year is fine, the wind generally becomes stronger as the time of the day advances, and dies away towards the evening, and assumes that pleasing serenity so delightful to our feelings. Such are the diurnal changes of the wind in northern climates. The annual revolution of the sun produces still more sensible effects. The prevalence of the western winds during summer we may attribute to this cause, which is still more perceptible in France and Spain, because the continent of land to the eastward, being heated more than the waters of the Atlantic ocean, the air is drawn during that season towards the east, and consequently produces a western wind. But these effects are much more perceptible in countries near the tropics than with us. For when the sun approaches the tropic of Cancer, the soil of Persia, Bengal, China, and the adjoining countries, becomes so much more heated than the sea to the southward of those countries, that the current of the general trade-wind is interrupted, so as to blow at that season from the south to the north, contrary to what it would do if no land was there. But as the high mountains of Africa during all the year are extremely cold, the low countries of India, to the eastward of it, become hotter than Africa in summer, and the air is naturally drawn thence to the eastward. From the same cause it follows that the trade-wind in the Indian ocean, from April till October, blows in a north-east direction, contrary to that of the general trade-wind in open seas in the same latitude; but when the sun retires towards the tropic of Capricorn, these northern parts become cooler, and the general trade-wind assumes its natural direction.

Having given the most obvious causes of the periodical mon-

soons in the Indian seas, it is necessary to observe, that no monsoon takes place to the southward of the equator, except in that part of the ocean adjoining to New Holland. There the same causes concur to produce a monsoon, as in the northern tropic, and similar appearances take place. From October till April, the monsoons set in from the N. W. to S. E. opposite to the general course of the trade-wind on the other side of the line: and here also the general trade-wind resumes its usual course during the other months, which constitute the winter season in these regions. It may not be improper to conclude this account of the tropical winds, by enumerating some of the principal inflections of the monsoons.

Between the months of April and October the winds blow constantly from W.S.W. in all that part of the Indian ocean which lies between Madagascar and Cape Comorin, and in the contrary direction from October till April, with some small variation in different places, but in the Bay of Bengal these winds are neither so strong nor so constant as in the Indian ocean. It must also be remarked, that the S.W. winds in those seas are more southerly on the African side, and more westerly on the side of India; but these variations are not so great as to be repugnant to the general theory. The cause of this variation is, as was before intimated, that the mountainous lands of Africa are colder than the flatter regions of Arabia and India; consequently the wind naturally blows from these cold mountains, in the summer season, towards the warmer lands of Asia, which occasions those inflections of the wind to the eastward during the summer months. The peninsula of India lying so much farther to the south than the kingdoms of Arabia and Persia, adds greatly to this effect; because the wind naturally draws towards them, and produces that easterly variation of the monsoon which takes place in this part of the ocean, while the sandy deserts of Arabia draw the winds more directly northward near the African coast. A similar chain of reasoning will serve to explain any other inflections or variations that may occur in the perusal of books of travel, &c.

Variable Winds.—In the temperate zones the direction of the winds is by no means so regular as between the tropics. Even in the same degree of latitude, we find them often blowing in different directions at the same time; while their changes are frequently so sudden and so capricious, that to account for them has hitherto been found impossible. When winds are violent, and continue long, they generally extend over a large tract of country, and this is more certainly the case when they blow from the north or east than from any other points. By the multiplication and comparison of meteorological tables, some regular connexion between the changes of the atmosphere in different places may, in time, be observed, which may at last lead to a satisfactory theory of the winds. It is from such tables chiefly, that the following facts have been collected.

In Virginia, the prevailing winds are between the south-west, west, north, and north-west; the most frequent is the south-west, which blows more constantly in June, July, and August, than at any other season. The north-west winds blow most constantly in November, January, and February. At Ipswich in New England, the prevailing winds are also between the south-west, west, north, and north-east; the most frequent is the north-west. But at Cambridge, in the same province, the most frequent wind is the south-east. The predominant winds at New York are the north and west; and in Nova Scotia north-west winds blow for three-fourths of the year. The same wind blows most frequently at Montreal in Canada; but at Quebec the wind generally follows the direction of the river St. Lawrence, blowing either from the north-east or south-west. At Hudson's Bay, westerly winds blow for three-fourths of the year; the north-west wind occasions the greatest cold, but the north and north-east are the vehicles of snow.

It appears from these facts that westerly winds are most frequent over the whole eastern coast of North America; that in the southern provinces, south-west winds predominate; and that the north-west become gradually more frequent as we approach the frigid zone.

In Egypt, during part of May, and during June, July, August, and September, the wind blows almost constantly from the north, varying sometimes in June to the west, and in July to the west and the east; during part of September, and in

October and November, the winds are variable, but blow more regularly from the east than any other quarter; in December, January, and February, they blow from the north, north-west, and west; towards the end of February they change to the south, in which quarter they continue till near the end of March; during the last days of March, and in April, they blow from the south-east, south, and south-west, and at last from the east; and in this direction they continue during a part of May. In the Mediterranean the wind blows nearly three-fourths of the year from the north; about the equinoxes there is always an easterly wind in that sea, which is generally more constant in spring than in autumn. These observations do not apply to the gut of Gibraltar, where there are seldom any winds except the east and west. At Bastia, in the island of Corsica, the prevailing wind is the south-west. In Syria the north wind blows from the autumnal equinox to November; during December, January, and February, the winds blow from the west and south-west, in March they blow from the south, in May from the east, and in June from the north. From this month to the autumnal equinox, the wind changes gradually as the sun approaches the equator, first to the east, then to the south, and lastly to the west. At Bagdad the most frequent winds are the south-west and north-west; at Pekin the north and the south; at Kamtschatka, on the north-east coast of Asia, the prevailing winds blow from the west.

In Italy the prevailing winds differ considerably, according to the situation of the places where the observations have been made; at Rome and Padua they are northerly, at Milan easterly. All that we have been able to learn concerning Spain and Portugal, is, that on the west coast of these countries, the west is by far the most common wind, particularly in summer; and that at Madrid the wind is north-east for the greatest part of the summer, blowing almost constantly from the Pyrenean mountains. At Berne in Switzerland, the prevailing winds are the north and west; at St. Gothard the north-east; at Lausanne the north-west and south-west.

Father Cotte has given us the result of observations made at 86 different places of France; from which it appears, that along the whole south coast of that kingdom the wind blows most frequently from the north, north-west, and north-east; on the west coast, from the west, south-west and north-west; and on the north coast from the south-west. That in the interior parts of France, the south-west wind blows most frequently in 18 places; the west wind in 14; the north in 13; the south in 6; the north-east in 4; the south-east in 2; the east and north-west each of them one. On the west coast of the Netherlands, as far as Rotterdam, the prevailing winds are probably the south west, at least this is the case at Dunkirk and Rotterdam. It is probable also, that along the rest of the coast, from the Hague to Hamburg, the prevailing winds are the north-west, at least these winds are most frequent at the Hague and at Franeker. The prevailing wind at Delft is the south-east; and at Breda, the north and the east.

In Germany, the east wind is most frequent at Göttingen, Munich, Weissenfels, Dusseldorf, Saganum, Erford, and at Buda in Hungary; the south-east at Prague and Wurtzburg; the north-east at Ratisbon; and the west at Mannheim and Beria. From an average of ten years of the register kept by order of the Royal Society, it appears that at London the winds blow in the following order:

Winds.	Days.	Winds.	Days.
South-west,	112	South-east,	32
North-east,	58	East,	26
North-west,	50	South,	18
West,	53	North,	16

It appears, from the same register, that the south-west wind blows at an average more frequently than any other wind during every month of the year, and that it blows longest in July and August; that the north-east blows most constantly during January, March, April, May, and June, and most seldom during February, July, September, and December; and that the north-west wind blows oftener from November to March, and more seldom during September and October than any other wind. The south-west winds are also most frequent at Bristol, and next to them are the north-east.

The following table of the winds at Lancaster has been drawn up from a register kept for seven years at that place.

Winds.	Days.	Winds.	Days.
South-west,	92	South-east,	35
North-east,	67	North,	30
South,	51	North-west,	26
West,	41	East,	17

The following table is an abstract of nine years' observations made at Dumfries by Mr. Copland :

Winds.	Days.	Winds.	Days.
South,	82½	North,	36½
West,	69	North-west,	25½
East,	68	South-east,	28½
South-west,	50½	North-east,	14½

The following table is an abstract of seven years' observations made by Dr. Meek at Cambuslang, near Glasgow :

Winds.	Days.	Winds.	Days.
South-west,	174	North-east,	104
North-west,	40	South-east,	47

It appears from the register from which this table was extracted, that the north-east wind blows much more frequently in April, May, and June, and the south-west in July, August, and September, than at any other period. The south-west is by far the most frequent wind all over Scotland, especially on the west coast. At Salcoats, in Ayrshire, for instance, it blows three-fourths of the year; and along the whole coast of Murray, on the north-east side of Scotland, it blows for two-thirds of the year. East winds are common over all Great Britain during April and May; but their influence is felt most severely on the eastern coast.

The following table exhibits a view of the number of days during which the westerly and easterly winds blow in a year at different parts of the island. Under the term westerly are included the north-west, west, south-west, and south; the term easterly is taken in the same latitude.

Years of Observation.	Places.	Wind.	
		Westerly.	Easterly.
10	London,	233	132
7	Lancaster,	216	149
51	Liverpool,	190	175
9	Dumfries,	227.5	137.5
10	Brånsholm, 54 miles south-west of Herwick,	232	133
7	Cambuslang,	214	151
8	Hawkhill, near Edinburgh,	229.5	135.5
	Mean	220.3	144.7

In Ireland the south-west and west are the grand trade-winds, blowing most in summer, autumn, and winter, and least in spring. The north-east blows most in spring, and nearly double to what it does in autumn and winter. The south-east and north-west are nearly equal, and are most frequent, after the south-west and west.

At Copenhagen the prevailing winds are the east and south-east; at Stockholm, the west and north. In Russia, from an average of a register of 16 years, the winds blow from November to April in the following order:

	W.	N.W.	E.	S.W.	S.	N.E.	N.	S.E.
Days 45	26	23	22	20	19	14	13	

and during the other six months,

	W.	N.W.	E.	S.W.	S.	N.E.	N.	S.E.
Days 27	27	19	24	22	15	32	18	

The west wind blows during the whole year 72 days; the south-west 56; the south-west and north 46 days each. During summer it is calm for 41 days, and during winter for 21. In Norway, the most frequent winds are the south, the south-west, and the south-east. The wind at Bergen is seldom directly west, but generally south-west or south-east; a north-west, and

especially a north-east wind, are but little known there. From the whole of these facts, it appears that the most frequent winds on the south coasts of Europe, are the north, the north-east, and north-west, and on the western coast the south-west: that in the interior parts, which lie more contiguous to the Atlantic ocean, south-west winds are also most frequent; but that easterly winds prevail in Germany. Westerly winds are also more frequent on the north-east coast of Asia. It is probable that the winds are more constant in the south temperate zone, which is in a great measure covered with water, than in the north temperate zone, where their direction must be frequently interrupted and altered by mountains and other causes.

M. De la Caille, who was sent thither by the French king to make astronomical observations, informs us, that at the Cape of Good Hope the principal winds are the south-east and north-west; that other winds seldom last longer than a few days; and that the east and north-east winds blow very seldom. The south-east wind blows in most months of the year, but chiefly from October to April; the north-west prevails during the other six months, bringing along with it rain, and tempests, and hurricanes. Between the Cape of Good Hope and New Holland, the winds are commonly westerly, and blow in the following order: north-west, south-west, west, north.

In the Great South Sea, from latitude 30° to 40° south, the south-east trade-wind blows most frequently, especially when the sun approaches the tropic of Capricorn; the wind next to it in frequency is the north-west, and next to that is the south-west. From south latitude 40° to 50°, the prevailing wind is the north-west, and next the south-west. From 80° to 60°, the most frequent wind is also the north-west, and next to it is the west. Thus it appears that the trade-winds sometimes extend farther into the south temperate zone than their usual limits, particularly during summer; that beyond their influence the winds are commonly westerly, and that they blow in the following order: north-west, south-west, west. Such is the present state of the history of the direction of the winds. In the torrid zone they blow constantly from the north-east on the north side of the equator, and from the south-east on the south side of it. In the north temperate zone they blow most frequently from the south-west; in the south temperate zone from the north-west, changing, however, frequently to all points of the compass; and in the north temperate zone blowing particularly, during spring, from the north-east.

Force and Velocity of the Wind.—As to the velocity of the wind, its variations are almost infinite; from the greatest breeze to the hurricane which tears up trees and blows down houses. It has been remarked that our most violent winds take place when neither the heat nor the cold is greatest; that violent winds generally extend over a great tract of country, and that they are accompanied by sudden and great falls in the mercury of the barometer. The reason appears to be, that violent winds succeed the precipitation in rain of a large quantity of vapour, which previously constituted a part of the bulk of the atmosphere; and this precipitation cannot take place when the general temperature approaches to either extreme. The wind is sometimes very violent at a distance from the earth, while it is quite calm at its surface. On one occasion Lunardi went at the rate of 70 miles an hour in his balloon, though it was quite calm at Edinburgh when he ascended, and continued so during his whole voyage. The same thing happened to Garnerin and his companion in their aerostatic voyage to Colchester; they having been carried from London to Colchester, a distance of at least 60 miles, in three quarters of an hour, making the velocity of the wind, at that time, 80 miles per hour, or 1½ mile per minute. This again may be illustrated by the motions of dense fluids, which are always impeded in the parts contiguous to the sides and bottoms of the vessels; and the same thing happens in tide rivers, where the boatman, when he wishes to proceed with the tide, commits himself to the middle of the stream; but when he has to strive against it, he keeps close to the shore. It is, therefore, not the upper parts of the atmosphere which are accelerated, but the lower are retarded by friction against the surface of the earth.

The following table, drawn up by Mr. Smooton, will give the reader a pretty precise idea of the velocity of the wind in different circumstances:

Miles per Hour.	Feet per Second.	Perpendicular Force on one square Foot, in Avoirdupois Pounds and Parts.
1	1.47	.006 Hardly perceptible.
2	2.93	.020 } Just perceptible.
3	4.4	.044 }
4	5.87	.079 } Gently pleasant.
5	7.33	.123 }
10	14.67	.492 } Pleasant, brisk.
15	22	1.107 }
20	29.34	1.968 } Very brisk.
25	36.67	3.075 }
30	44.01	4.429 } High wind
35	51.34	6.027 }
40	58.68	7.873 } Very high wind.
45	66.01	9.963 }
50	73.35	12.300 } Storm or tempest.
60	88.02	17.715 } Great storm.
80	117.36	31.490 } Hurricane.
100	146.7	49.200 } Hurricane that tears up trees, and carries buildings before it.

WIND-Gage. See ANEMOMETER, where the velocity of the wind is fully treated of.

WIND, with regard to a ship's course, is termed a foul wind, or a fair wind, a scant wind or a leading wind: these terms being respectively opposed to each other.

WIND'S Eye, implies the direct point from which the wind blows.

Between Wind and Water, signifies that part of a ship's bottom which is frequently brought above the water by her agitation when at sea.

WIND Sails, in a ship, are made of the common sail-cloth, and are usually between 25 and 30 feet long, according to the size of the ship, and are in the form of a cone ending obtusely.

WINDAGE, the difference between the diameter of a piece of artillery, and the diameter of the shot or shell corresponding thereto.

WINDING A CALL, the act of blowing or piping on a boat-swain's whistle, so as to communicate the necessary orders of hoisting, heaving, belaying, veering away, &c.

WINDING Tackle, a name usually given to a tackle, formed of one fixed triple block, and one double or triple moveable block. It is principally employed to hoist up any weighty materials, such as the cannon, into or out of a ship.

WINDLASS, a machine used in merchant ships instead of a capstan, to heave up the anchors from the bottom, &c. It is a large cylindrical piece of timber, moving round on its axis in a vertical position, and is supported at its two ends by two pieces of wood, called knight-heads, which are placed on the opposite sides of the deck near the fore-mast; it is turned about by levers, called handspikes, which are for this purpose thrust into holes bored through the body of the machine. The lower part of the windlass is usually about a foot above the deck. It is, like the capstan, furnished with strong pauls, to prevent it from turning backwards by the effort of the cable, when charged with the weight of the anchor, or strained by the violent jerking of the ship in a tempestuous sea. The pauls, which are formed of wood or iron, fall into notches cut in the surface of the windlass, and lined with plates of iron. Each of the pauls being accordingly hung over a particular part of the windlass, falls eight times into the notches at every revolution of the machine; because their eight notches are placed on its circumference under the pauls: so, if the windlass is twenty inches in diameter, and purchases five feet of the cable at every revolution, it will be prevented from turning back, or losing any part thereof, at every seven inches, nearly, which is heaved in upon its surface. As this machine is heaved about in a vertical direction, it is evident that the effort of an equal number of men acting upon it will be much more powerful than on the capstan; because their whole weight and strength are applied more readily to the end of the lever employed to turn it about; whereas, in the horizontal movement of the capstan, the exertion of their force is considerably diminished. It requires,

however, some dexterity and address to manage the handspike to the greatest advantage; and to perform this, the sailors must all rise at once upon the windlass, and, fixing their bars therein, give a sudden jerk at the same instant, in which movement they are regulated by a sort of song or howl pronounced by one of their number.

Spanish WINDLASS, is a machine formed of a handspike and a small lever, usually a tree-nail, to set up the top-gallant rigging, or for any other short steady purchase.

WINDMILL. See MILL.

WIND-RODE, is a term applied to a ship, which, riding where the wind and tide are opposed to each other, is forced by the violence of the former to remain to leeward of her anchor.

WIND-SAIL, a sort of wide tube or funnel of canvass, employed to convey a stream of fresh water downwards into the lower apartments of a ship, being let down through the hatches, and kept extended by means of several wooden booms; the upper part is open on one side, which is braced to the wind so as to receive the full current of it, which fills the tube, and rushes downward into the lower regions of the ship. Ships of war have generally, in hot climates, three or four of these wind-sails, for the preservation of the crew's health.

WINE. All wines contain an acid, alcohol, tartar, extract, aroma, and colouring matter. The presence and nature of each of these principles may be ascertained in the following way: 1. Acid. All wines, even the softest and mildest, reddish limus, and therefore contain an acid. This abounds, however, chiefly in the thin wines of wet and cold climates, where the grape juice or must contains but a small portion of sugar. When wine has been boiled to extract the brandy, the liquor which remains in the still, and is thrown away as useless, is a sour nauseous fluid with an acrid and burnt flavour. When filtered, and allowed to remain at rest for a time, it deposits a good deal of extractive matter, becomes covered with mould, and then contains a notable quantity of acetous acid, which may be separated by distillation. The acid is however not entirely acetous, at least not till after standing a considerable time, for it precipitates and forms an insoluble salt with lime water, and with the insoluble salts of silver, lead, and mercury, appears to be the malic acid mixed with a little citric, both of which are converted into vinegar by spontaneous decomposition. The wines that contain the greatest quantity of these acids yield the worst brandy, nor is there any method yet known of separating or neutralizing the acid without materially injuring the quality, or lessening the quantity of the ardent spirit. 2. Alcohol. The existence of this principle, and mode of extraction by distillation, has been described under the article DISTILLATION. The quantity of alcohol varies prodigiously. The strong, rich, full-bodied wines of the warmer wine countries will yield as much as a third of ardent spirit; whilst the thin light wines will often give no more than about one sixteenth of the same strength. 3. Tartar. This substance has also been fully described in its proper place. Tartar is not altogether a product of the fermentation of wine, since it is contained in must, though in small quantity. 4. Extract. Must contains an abundance of extractive matter, which materially assists the fermentation, and is afterwards found, in part at least, in the lees, but another portion may be obtained from the wine by evaporation. It is also extract that mixes with and colours the tartar. By age the quantity of extractive matter diminishes. 5. Aroma. All wines possess a peculiar and grateful smell, which would indicate a distinct aromatic principle, but it has never been exhibited in the form of essential oil, or condensed in any smaller quantity by distillation or any other mode. To give wine all its aroma, it should be fermented very slowly. 6. Colouring matter. The husk of the red grape contains a good colour, which is extracted when the entire fruit is pressed, and becomes dissolved in the wine when the fermentation is complete. Many substances will separate the colour. If lime water is added to high-coloured wine, a precipitate is formed of malat of lime, that carries down with it all the colouring matter, which cannot again be separated either by water or alcohol. But if wine alone is evaporated gently to dryness, and the residue treated with alcohol, the colouring matter dissolves therein. We may add, too, that the natural colour of wine is entirely and speedily destroyed by the addition of hot well-burnt charcoal in pretty

often that which is made of Malaga's (especially if the fruit be but indifferent) will not hold its colour, but must have a colour laid on it. The right colour of raisin wine is the colour of mountain. You must take care that your wine has not a great bottom in it; for if it has, it will be longer before it falls fine. In order to lay a mountain colour on your wine, you must take three or four pounds of brown sugar, according to the quantity of wine you want to colour. Put it in an iron pan or iron ladle, set it over the fire, and keep stirring it about. Let it burn in this manner till it is quite black and bitter, which will be about half an hour. If you burn one pound of sugar, put a quart of boiling hot water to it; stir it about, and let it boil a quarter of an hour longer, then take it off and let it cool. A pint of this mixture is sufficient to colour a pipe of wine; but note, that with every pint you must mix a quarter of an ounce of common alum pounded to a fine powder; which will set the colour so that it will not subside, otherwise it will fall to the bottom, and have no good effect on the liquor. If you would have your wine of the colour of port, you must take eight ounces of log-wood raspings, four ounces of alkanet root, and one ounce of cochineal. Infuse them over a slow fire for three hours, strain the liquor from the wood, and keep it boiling. Then burn three pounds of brown sugar as before, and put the coloured liquor to it; boil all together a quarter of an hour longer; then take it off, and when cold bottle it for use. A pint of this liquor will make a pipe the colour of port wine. You must always remember to set the colour with a quarter of an ounce of common alum, ground or beaten to a fine powder.

Wine from Apples.—The Danish chemist, Oersted, has demonstrated, that, of all the fruits which grow in Denmark, the apple, mixed with a great quantity of sugar, produces a drink which more nearly resembles wine than any other substitute. Cherries, gooseberries, and other fruits, from which a vinous liquor is extracted, are not so proper for it. He hopes, before many years, to make very good wine with apple juice and sugar.

WINGERS, small casks stowed close to the side in a ship's hold, where the large casks would cause too great a rising in that part of the tier.

WINGS, a name given to those parts of the hold and orlop-deck which are nearest to the sides. This term is particularly used in the stowage of the several materials contained in the hold.

WINGS, are also the skirts or extremities of a fleet, when ranged in a line abreast, or when forming two sides of a triangle. It is usual to extend the wings of a fleet in the day-time, in order to discover any enemy that may fall in their track; they are, however, commonly summoned by signal to draw nearer to the centre of the squadron before night.

WINNOWING MACHINES. Machines of this sort are in pretty general use where thrashing mills, to which they may be attached, are not erected; they are made on different principles, according to particular circumstances.

WIRE DRAWING, is the art of drawing out long bars of metal, by pulling it through holes in a plate of steel, or other fit metallic compound. In order that a wire may be drawn, it is requisite that the metal should have considerable tenacity. Gold, silver, iron, steel, copper, and their compounds, are most commonly used in the arts. The process is of considerable simplicity.—A number of holes, progressively smaller and smaller, are made in a plate of steel, and the pointed end of a bar of metal being passed through one end of them, is forcibly drawn by strong pinchers, so as to elongate it by the pressure arising from the re-action of the greatest hole. This is the wire; and it is again passed in like manner through another hole, a little smaller; and by continuing the process, the wire has its length increased and its diameter diminished to a very great degree. The largest wire may be nearly an inch in diameter, and the smallest ever made was about the one-thousandth part of an inch; but it is said that silver wire has been made one-fifteen-hundredth of an inch in diameter. The size of these small wires may be ascertained from the weight of a known measure, of length and the specific gravity of the metal; or, less correctly, the wire may be wound round a pin, and the number of turns counted to make a given length. Wires are drawn square, and of other figures in their sector. In particular, they are drawn grooved, so that any small part will form the pinion of a watch

or clock-work. As the violent action of the drawing-plate renders the wire hard and brittle, it is necessary to anneal it several times during the course of drawing. Very small holes are made by hammering up the larger, and the point, in very thin wire, by rolling or crushing the end by a smooth burnishing tool, upon a polished plate. Gold and silver wire is made of cylindrical ingots of silver, covered over with a skin of gold, and thus drawn successively through a vast number of holes, each smaller and smaller, till at last it is brought to a fineness exceeding that of a hair. That admirable ductility which makes one of the distinguishing characters of gold, is no where more conspicuous than in this gilt wire. A cylinder of 48 ounces of silver, covered with a coat of gold only weighing one ounce, as Dr. Halley informs us, is usually drawn into a wire, two yards of which weigh no more than one grain; whence, 98 yards of the wire weigh no more than 49 grains; and one single grain of gold covers the 98 yards; so that the thousandth part of a grain is above one-eighth of an inch long. He also, on computing the thickness of the skin of gold, found it to be $\frac{1}{1000}$ part of an inch. Yet so perfectly does it cover the silver, that even a microscope does not discover any appearance of the silver underneath. Mr. Robault likewise observes, that a like cylinder of silver, covered with gold 2 feet 8 inches long and 2 inches 9 lines in circumference, is drawn into a wire 307,200 feet long,—115,200 times its former length. M. Boyle relates, that eight grains of gold covering a cylinder of silver, are commonly drawn into a wire 13,000 feet long. Silver wire is the same with gold wire, except that the latter is gilt, or covered with gold, and the other is not. There are also counterfeit gold and silver wires,—the first made of a cylinder of copper silvered over, and then covered with gold, and the second a cylinder of copper silvered over and drawn through iron in the same manner as gold and silver wire. Brass wire is made in the same way.

WIT, a faculty of the mind, consisting, according to Mr. Locke, in the assembling and putting together of those ideas, with quickness and variety, in which any resemblance or congruity can be found, in order to form pleasant pictures and agreeable visions to the fancy. This faculty, the same author observes, is just the contrary of judgment, which consists in the separating carefully from one another, such ideas, wherein can be found the least difference, thereby to avoid being misled, by similitude and affinity, from taking one thing for another.

WITNESS, one who is sworn to give evidence in a cause. If a man is subpoenaed as a witness upon a trial, he must appear in court, on pain of 100*l.* to be forfeited to the king, and 10*l.* together with damages equivalent to the loss sustained by the want of his evidence, to the party aggrieved. But witnesses ought to have a reasonable time, that their attendance upon the court may be of as little prejudice to themselves as possible: and the court of king's bench held, that notice at two in the afternoon to attend the sitting that evening at Westminster, was too short a time. Where a witness cannot be present at a trial, he may, by consent of the plaintiff and defendant, or by rule of court, be examined upon interrogatories at the judge's chambers. No witness is bound to appear to give evidence in a cause, unless his reasonable expense is tendered him; nor need he appear till such charge is actually paid him, except he both resides and is summoned to give evidence within the bills of mortality.

WOLFF or **WOLFIUS**, CHRISTIAN, an eminent philosopher, born at Breslau, 1679. At Jena university he made a most extraordinary progress, and in 1792 he repaired to Leipsic, where he opened his lectures by a famous dissertation, called "*Philosophia practica universalis methodo mathematica conscripta*." This great man, whose life was devoted to advance science and virtue, died at Halle of the gout in his stomach, 1754, aged 76. His works in Latin and German are more than sixty in number, the best of which known are, *A Course of Mathematics*, 2 vols. 4to. *A Dictionary on the Mathematics*, &c.

WOLFRAM, an ore of tungsten, is found in different parts of Germany, in Sweden, Britain, France, and Spain; and almost constantly accompanied by ores of tin. It occurs both massive and crystallized. The primitive form of its crystals is a rectangular parallelepiped, whose length is 8.66, whose breadth is 5, and thickness 4.33. Colour brown or brownish

black. Streak reddish brown. Powder stains paper with the same colour. Texture foliated. Easily separated into plates by percussion. Specific gravity from 7. to 7.3. Moderately electric by communication. Not magnetic. Infusible by the blowpipe. Forms with borax a greenish globule, and with microcosmic salt a transparent globule of a deep red.

WOOD, CUTTING IN, is used for various purposes; as for initial and figured letters, head and tail pieces of books; and even for mathematical schemes and other figures, to save the expense of engraving on copper; and for prints and stamps for papers, calicoes, linens, &c. The invention of cutting in wood, as well as that of copper, is ascribed to a goldsmith of Florence, but Albert Durer and Lucas brought both those arts to perfection. About 200 years ago, the art of cutting in wood was carried to a very great pitch, and might even vie for beauty and justness with that of engraving on copper. It has also of late years been much used, and it is convenient where numerous cheap embellishments are wanted for a work. The figure is drawn upon the wood, and all that part which is to be left white is cut away, and the rest left. A wood-engraving after printing 100,000 is as good as ever; and the expense in printing is not more than that of letter-press. See **STRENGTH OF MATERIALS**.

Dyeing Wood. General Observations. It being necessary to say something as to the quality, nature, and texture of the wood most fit for dyeing, we shall state our remarks in the following order:—First, the wood mostly used to dye black, is pear-tree, holly, and beech, all of which will take a beautiful black; it should at the same time be observed, not to take wood which has been long cut, or aged, but as fresh as possible; we have likewise found that after the veneers have had one hour's boiling, and taken out to cool, that the colour has struck much stronger. It should likewise be noticed, that after the veneers are dyed, they should be dried in the air and not by the fire, or in a kiln of any kind; as it tends to destroy the colour. Secondly, in order to dye blue, green, red, or other colours, take clear holly; put the veneers first in a box or trough with clean water, and let them remain four or five days, changing the water once, or twice, as you find occasion; the water, acting as a purgative in the wood, will bring forth abundance of slime, &c.; let them dry about twelve hours before they are put in the dye; by observing this, you will find the colour strike quicker, and be of a brighter hue.

Fine Black.—Have a chair-maker's copper fixed, into which put six pounds of chip logwood, and as many veneers as it will conveniently hold without pressing too tight; fill it with water, and let it boil slowly for about three hours; then add half a pound of powdered verdigrise, half a pound of copperas, and four ounces of bruised nut galls, filling the copper up with vinegar as the water evaporates; let it boil gently two hours each day, till you find the wood to be dyed through, which according to the kind will be in more or less time.

Fine Blue.—Take a clean glass bottle, into which put one pound of oil of vitriol; then take four ounces of the best indigo, pounded in a mortar into small lumps; put them in a phial, (taking care to set the bottle in a basin or earthen-glazed pan, as it will ferment): after it is quite dissolved, provide an earthen or wooden vessel, so constructed that it will conveniently hold the veneers you mean to dye; fill it rather more than one third with water, into which pour as much of the vitriol and indigo (stirring it about), as will make a fine blue; which you may know by trying it with a piece of white paper or wood; put in your veneers, and let them remain till the dye has struck through. **Note.** The colour will be much better if the solution of indigo in vitriol is kept a few weeks before using it; also the best trough you can use, being either made of common stone like a stone sink, but of proper dimensions, say about four feet by eight or nine inches, which will be sufficiently large for veneers intended to be stained; or you may procure one made of artificial stone of any dimension, which will not cost so much; also you will find the colour strike better if, previous to putting your veneers into the blue dye, you boil them in plain water till completely soaked through, and let them remain for a few hours to dry partially, previous to immersing them in the dye.

Fine Yellow.—Take of the root of barberry four pounds, reduce it by sawing to dust, which put in a copper or brass

trough, add four ounces of turmeric, to which put four gallons of water, then put in as many white holly veneers as the liquor will cover; boil them together for three hours, often turning them; when cool, add two ounces of aqua-fortis, and you will find the dye strike through much sooner.

Bright Green.—Proceed as in the above receipt to produce a yellow; but instead of adding aqua-fortis or the brightening liquid, add the vitriolated indigo, as much as will produce the desired colour.

Bright Red.—Take two pounds of genuine Brazil dust, add four gallons of water, put in as many veneers as the liquid will cover, boil them for three hours; then add two ounces of alum and two ounces of aqua-fortis, and keep it lukewarm until it has struck through.

Purple.—Take two pounds of chip logwood, and half a pound of Brazil dust, add four gallons of water, and after putting in your veneers, boil them well for at least three hours; then add six ounces of pearl ash and two ounces of alum, let them boil two or three hours every day, till you find the colour struck through. **Note.** The Brazil dust in this receipt is perhaps superfluous, as it only contributes to make the purple of a redder cast, for the pearl-ash does not act upon it to change it from a red to a purple.

Orange.—Let the veneers be dyed, by the method given, of a fine deep yellow, and while they are still wet and saturated with the dye, transfer them to the bright red dye, till you find the colour has penetrated equally throughout.

WOODY FIBRE, is procured from the wood, bark, leaves, or flowers of trees, by exposing them to the repeated action of boiling water, and boiling alcohol. It is the insoluble matter that remains, and is the basis of the solid organized parts of plants. There are as many varieties of woody fibres, as there are plants and organs of plants; but they are all distinguished by their fibrous texture, and their insolubility. Woody fibre burns with a yellow flame, and produces water and carbonic acid in burning. When it is distilled in close vessels, it yields a considerable residuum of charcoal. It is from woody fibre, indeed, that charcoal is procured for the purposes of life. M. Gay Lussac and Thenard have concluded from their experiments on wood of the oak, that 100 parts contain of carbon, 52.63; of oxygen, 41.78; hydrogen, 5.69.

WOOL, the covering of sheep. Each fleece consists of wool of several qualities and degrees of fineness, which the dealers therein take care to separate. The fineness and plenty of our wool is owing in a great measure to the short sweet grass in many of our pastures and downs: though the advantage of our sheep feeding on this grass all the year without being obliged to be shut up under cover during the winter, or to secure them from wolves at other times, contributes not a little to it.

WOOLCOMBERS. By 35 G. III. c. 124, all those who have served an apprenticeship to the trade of a woolcomber, or who are by law entitled to exercise the same, and also their wives and children, may set up and exercise such trade, or any other trade or business they are apt and able for, in any town or place within this kingdom, without any molestation: nor shall they be removable from such place by the poor laws.

WOOLING, the act of winding a piece of rope about a mast or yard, to support it in a place where it is fished or scarfed, or when it is composed of several pieces united in one solid. **Woolding,** is also the rope employed in this service.

WOOTZ. The metal extracted from some kind of iron ore in the East Indies, apparently of good quality. It contains more carbon than steel and less than cast iron, but from want of skill in the management is far from homogeneous.

WORD, WATCH, is a peculiar word that serves for a token and mark of distinction given out in the orders of the day in time of peace, but in war every evening in the field, by the general who commands, and in garrison by the governor, or other officer commanding in chief, to prevent surprise, and hinder an enemy, or any treacherous person, from passing backwards and forwards. It may be changed whenever circumstances render it necessary. Its importance depends upon its being known only to the party interested in keeping it a secret. To communicate it to the enemy is a capital offence.

WORD, in Language, an articulate sound representing some idea or conception of the mind. The copiousness of the English

language is proved by the following enumeration of the words in Johnson's Dictionary: Articles 3—Nouns substantive 20409—Adjectives 9053—Pronouns 41—Verbs 7880; that is, active 5445; neuter 2425; passive 1; defective or imperfect 5; auxiliary 1; impersonal 3—Verbal noun 1—Participles 38—Participial adjectives 125—Participial nouns 3—Adverbs 496; Adverbs in *ly* 2096; total 2592—Prepositions 69—Conjunctions 19—Interjections 68.—Total 40,301.

It must be remarked, however, that in this list many of the compound words are not reckoned; that the participles are those only having no verbs to which they may be referred, as *Beloved*; that though so few verbal and participial nouns are stated by Johnson, yet every active participle may supply one of the former description, and every verb one of the latter; and that both these (verbal and participial nouns) seem to be merely different applications of a true gerund.

WORK (To), to direct the movements of a ship, by adapting the sails to the force and direction of the wind. A ship is also said to work when she strains and labours heavily in a tempestuous sea, so as to loosen her joints or timbers. *To Work Double Tides*, a phrase used in the dock-yards, implying that the people perform the work of three days in two. *To Work up Junk*, to draw yarns from old cables, &c. and therewith to make foxes, points, gaskets, sinnet, or spun-yarn.

WORKING IN HARVEST. A person may go abroad to work in harvest, carrying with him a certificate from the minister, and one churchwarden or overseer, that he has a dwelling-house, or place in which he inhabits, and that he has left a wife and children, or some of them there (or otherwise as his condition shall require), and declaring him an inhabitant there.

WORKING TO WINDWARD, the operation by which a ship endeavours to make a progress against the wind.

WORMING, the act of winding a rope spirally about a cable, so as to lie close along the interval between every two strands; a smaller rope is wormed with spun-yarn. It is generally used as a preparative for serving, and causes the service to lie smooth and round. This is also called *Link-Worming*. Cables may frequently be preserved by means of chains twisted round them in the following manner:—Take three chains of about fifteen fathoms each in length, all of an equal size, and proportioned in thickness to the nature of the case. Let them be wound round the cable, so that they may project sufficiently to receive the greatest part of the friction, one end of them being fastened to the ring of the anchor, and each chain being from thence wormed round its respective hollow or channel of the cable, so as not to check it from stretching. Fasten the other ends of the chains to the cable. It is not necessary that the chains should be very heavy, but extremely advisable that the links should be short, because they will be thereby more pliant, and worn much easier. These chains will completely guard the cable against the chafing of the rocks, and they may be put on in a few minutes, so that it is unnecessary to have them fitted on, but when it is probable they may be really serviceable. A due attention to shortening cables at the slack of the tide, and veering out as it flows, must also be highly important to prevent their being damaged. But it frequently happens that cables are suffered to kink, as it is called, through inattention to these circumstances, and to avoid a little trouble. If the wind should freshen when they are in this condition, though the cables be ever so good, the first foul sea that comes against them is almost sure to occasion their snapping; and vessels may be driven on shore, and much damaged, at least, if not totally lost, before they can possibly be brought up to other anchors, that may not always be in a state of readiness; for if there be an inattention and carelessness in one respect, there may be the same probably in others of equal importance. As the weight of the three chains, even for a large cable, will not exceed 500 pounds weight, the only difficulty which remains to be obviated will arise from the smallness of the hawse-holes, but these could be enlarged in vessels that shall deem it of sufficient moment to make the trial, and with the additional resistance of a boy or spare man at the head of the vessel, to cast off the chains as they come up, and hand them in above, all inconvenience will be removed. Admitting, indeed, that it may take up a few minutes more to weigh an anchor so secured than a common one, surely this can be no

argument against a measure that tends to preserve and ensure the safety of the vessel and ship's company.

It may not be improper to recommend further, in high latitudes, where ice may cut or damage the cables while riding at anchor, the use of three other chains of the same nature as the preceding, but not more than five or six fathoms in length. These may be wormed round the cables in the same manner at the surface of the water, and will be an excellent means of guarding them from the ice, so as either to prevent its wounding them, or chafing them quite asunder: a circumstance which is not unprecedented in our harbours or rivers, but which frequently happens on the continent of Europe.

WORM, an instrument used to pieces of artillery, to draw the charge, or to take out the bottom of the cartridge, which sometimes remains in the chamber after firing, and which, by being on fire, might explode the next charge while being rammed home, whereby the man would probably lose both his hands; hence it is indispensably requisite that a gun should be wormed at least every third discharge.

WORM-eaten, the state of a plank, or of a ship's bottom, when a number of cavities are made in it by a particular kind of worm which abounds in the tropical climates.

WORMS. See *VERMES*.

WORSTED, a kind of woollen thread, which in the spinning is twisted harder than ordinary. It is chiefly used either wove or knit into stockings, caps, gloves, or the like.

WOULFE'S CHEMICAL APPARATUS for separating Gas from Vapour.—In every process of distillation, the matters separated and evolved by the application of heat, pass from the distilling vessel to the receiver, either in the form of vapour or of gas, or in both of these forms. If only vapour or steam be the product, it may, by cooling, be condensed into a liquid, in a common receiver of any kind; as takes place in distilling a spirit from wine, from wash, from ale, or other fermented vinous liquors. If the product be a gaseous fluid alone, that cannot be so condensed, it may prove to be soluble in water in a greater or less proportion; as in the distillation of muriatic acid, nitric acid, ammonia, &c. The matter evolved from the materials in the distilling vessel, may be partly vapour and partly gas. In this case the vapours may, as above, be condensed, and obtained in a liquid form; and the gas, if soluble in water, may, combined therewith, be obtained separately in a liquid solution. But the gas that comes over with the vapour may be insoluble in water. In this case, though the vapour, as before, may be condensed, the gas, without an appropriate apparatus, must be lost. To the want of such apparatus may be ascribed the comparatively slow progress that was for many ages made in chemical science. By means of a suitable apparatus, the gas, whether soluble or insoluble in water, whether accompanied or not with vapour in coming over, may be collected without any loss. When the gas evolved is partly soluble in water and partly insoluble, which sometimes happens, the soluble portion combined with water, the insoluble in the form of gas, and such liquid as may have been produced by the condensation of vapour, may all three be obtained separately and without any loss. To effect these objects with accuracy and facility remained a desideratum, till Woulfe's apparatus, so named from its inventor Peter Woulfe, was introduced into the laboratory.

Woulfe's Apparatus,—for chemical and pharmaceutical operations, is commonly formed of flint glass; but in large manufactories it is sometimes constructed partly of wood and partly of lead or other metals, according to circumstances. The following are the parts of which it is composed:—

Figure 1. A balloon with two openings; one to receive the beak of a retort, the other for introducing a connecting-tube, to join it to one of Woulfe's bottles.

Fig. 2, one of those bottles with two necks.

Fig. 3, another bottle with three necks.

Fig. 4, an adaptor, for making a communication between retorts, balloons, bottles, &c.

Connecting tubes are inserted in the necks of the bottles by means of perforated corks, in which a hole is made to fit the tubes, by employing a round file till the tubes may be firmly fixed in them. The outsides of the corks are made to fit the necks by means of a coarse file. Sometimes the bottles and

Fig. 2

Fig. 3

Fig. 4

Fig. 5

Fig. 6

connecting tubes are joined to each other by corks alone: at other times they are luted. In joining the retort with the balloon, or the adaptor with the retort and the bottles, lute alone should be employed, some of which should be pressed in at the place of juncture, that the vessels may be prevented, by means of the interposed lute, from touching each other. The least troublesome method of closing the junctures is, by having the connecting tubes ground as stoppers to fit the necks of the bottles; but as they are much exposed to the danger of being broken, they are often dispensed with on account of the cost.

Fig. 5, the apparatus with luted joinings, as arranged for distillation, in which both liquids and gases are produced.

Fig. 6, the apparatus as employed in distillations, in which the products pass over in the form of gas only: not luted, but furnished with refrigeratory vessels.

Fig. 7, a connecting tube with a small capillary safety-tube, *z*, attached to it.—Connecting tubes are generally made of glass, but better, when the products of the process admit of it, of lead tube, or of tubes made of caoutchouc.

We shall describe each of these arrangements, and illustrate them by actual examples of operation; and the latter being, in some respects, the simpler of the two, we shall begin with it.

When the product of the distillation is merely gaseous, but soluble in water, the earthen or glass retort, *r*, fig. 6, placed on the naked fire, or in a water-bath, or in a sand-bath, as the case may require, is joined by means of an adaptor *a*, with the central neck of the bottle *b*, in one of the side necks of which the safety-tube *s* is inserted, in such a manner as nearly to touch the bottom. The other neck of this bottle is made to communicate with the two-necked bottle *c* by means of the connecting-tube *e*, bent into the form of the letter *n*, but with unequal legs, so that the shorter leg reaches only within the neck of the bottle *b*, while the longer reaches almost to the bottom of the two-necked bottle *c*: this second bottle is combined in like manner with the third bottle *d*; but it is better that in this communication the connecting-tube should have a little capillary tube, as shewn at *z*, fig. 7, for the occasional admission of air when condensation or absorption takes place in the apparatus,—or, which is still preferable, the connecting tube may be joined with that kind of safety-tube represented at *f*, and which goes by the name of its inventor, Welter.—This would always be employed, but for its being very easily broken. Some people, however, prefer, on every occasion, three-necked bottles only, with safety-tubes in each, like the tube *s* shewn in the bottle *b*.

In the first bottle *b*, a sufficient quantity of water is introduced to have the safety-tube *s* immersed about half an inch; and in the second and third, that quantity which experience has shewn to be necessary for the absorption of the gas. The safety-tube *s* is left open, but the capillary tube *z*, when made use of in the second communication, is luted in such a manner that it may be quickly opened; or if Welter's tube be employed, a little mercury is introduced, to close the lower bend. The second neck of the third bottle, or of the last in the series, when more are employed, may be left open, or slightly closed with a cork. The substances to be operated on are introduced into the receiver through the tubulure, when a tubulated receiver is made use of, and (for the process which we shall hereafter describe) a stopper may be used in place of the bottle with the stop-cock shewn as in the plate, and the joinings may be luted. As soon as the substances in the retort begin to act on each other, the gas that is liberated mixes with the common air in the retort and in the bottle *b*, and pressing on the water in the descending limb of the connecting-tube *e*, in the second bottle *c*, at length makes its passage good into *c*, and rising in bubbles through the water therein, passes on, in like manner, to the bottle *d*. During this transition the gas is absorbed by the water, an effect which is promoted by the compression both of the gas and the water, also by the minute division and consequent increase of acting surfaces of gas, and by the cooling process carried on at the same time by means of the refrigeratory vessels exhibited in the plate,—the heat disengaged from the gas in passing to the liquid state, being often such as to cause the water to boil. But refrigeratory vessels are not always necessary. If, by accident or inattention, the heat be urged more than necessary, the gas will be produced in greater quantity

than the connecting tubes can pass: then water will be forced from the bottle *b* up the safety-tube, till the surface of the water in *b* is reduced low enough to admit common air. Thus the safety-tube prevents the apparatus from being broken. As the density of the water is increased by absorbing the gas, the passage of which to the next bottle is thereby rendered more difficult, it is better to employ a greater number of bottles than to have the water too high in those made use of. As soon as the development of the gas begins to decrease, the water of the tube of safety descends. This happens either towards the end of the operation, or when the heat is imprudently diminished. If the apparatus be then perfectly cooled, the air in the first bottle is condensed to such a degree, that the atmospheric air enters the tube of safety. But for this tube, the water contained in the second bottle would necessarily come over into the first. It would be the same with the third bottle, were not the capillary tube of the second communicating tube opened, and the atmospheric air admitted. If the communicating tube be without a capillary tube, the luting of the third bottle must be instantly opened, and the bottle itself removed. The height of the water in the safety-tube decreases also at last, in consequence of the second and third bottle becoming cooler, or when from any other cause the absorption of the gas is more rapid than its production. It also frequently happens in the midst of the operation, that the gas, instead of being evolved, is absorbed for a short time by the mass contained in the retort, or that the volume of this mass is otherwise suddenly diminished, which, in like manner, causes the water in the safety tube to fall. The safety-tube, therefore, not only defends the apparatus from breaking, but also prevents the fluids in the bottles from mixing. It serves moreover, as a mean by which we may judge of the progress of the operation. If, during the progress, a small quantity of gas, unabsorbed, is observed to pass through the open neck of the third bottle, a fourth bottle is immediately to be joined with the third, in the same manner as the third is connected with the second. But on this occasion it should be recollected, that the pressure is increased in the first bottle, and the safety-tube should be consulted. When the operation is finished and the apparatus cooled, the water contained in the bottles will be found impregnated with the developed gas, and more so in the first bottle than in the last. The liquor contained in the first bottle is frequently not quite pure, because the small quantity of the body which comes over in the liquid form carries along with it the impurities of the distilled substances; the other liquors are, however, perfectly pure. If the weight of the water poured into each bottle has been accurately determined, it will be easy, after the operation is finished, to ascertain in the most precise manner, from the increase of weight, not only the whole weight of the gas obtained, but also the degree of concentration of the fluids in each bottle. By way of example, we will state the result of a real operation.

Preparation of Liquid Ammonia.—To obtain liquid ammonia, formerly called volatile spirit of ammonia, and more commonly spirit of hartshorn, one pound and a half of dry muriate of ammonia, (sal ammoniac,) and four pounds and a half of quicklime, both in fine powder, were employed in the following manner:—Half a pound of lime was put at the bottom of the retort by itself; upon this was thrown a mixture of three and a half pounds of lime and one and a half pound of sal ammoniac: and lastly, the remaining half pound of lime was put in. The retort was placed on a sand bath, and connected with an apparatus of the nature before described. Distillation was now commenced, and continued, by a heat gradually increased to the ignition of the retort, till the gas ceased to come over. To immerse the tube of safety, three ounces of distilled water were poured into the bottle *b*, half a pound into *c*, and half a pound into *d*. When the apparatus was opened, the first bottle was found to contain 4 ounces 2 drams 40 grains of a foul weak solution of ammonia; the second bottle, 1½ ounce 28 grains of strong and pure liquid ammonia; and in the third bottle, 9½ ounces 3 drams 16 grains, of an equally pure but weaker solution.

Bottle.	Water.	Increase.		
<i>d</i>	3 ounces	1 ounce	2 drams	40 grains
<i>b</i>	8 ounces	4 ounces	—	28 grains
<i>c</i>	8 ounces	1 ounce	7 drams	16 grains
	19 ounces	7 ounces	2 drams	24 grains

From this it appears, that $1\frac{1}{2}$ pound of sal ammoniac afforded 7 ounces 2 drams 24 grains of pure ammoniacal gas, which, dissolved in 19 ounces of water, formed 26 ounces 2 drams 24 grains of liquid ammonia, of which the small portion contained in the first bottle being weak and impure, may be rejected; that contained in the second bottle was very strong, since two parts water contained one part of ammonia; that in the third portion was also pure, but weaker, the proportion of the ammonia to the water being about 1 : 5. The residue left in the retort, after the foregoing process, is muriate of ammonia. The rationale of the process is simply this: sal ammoniac is composed of muriatic acid, and pure ammon; and the chemical attraction of this acid being greater for lime than for ammonia, it combines with the lime, liberating the ammonia, which assumes the gaseous form.

Pure ammonia—the base of the gas produced in the manner that has been described, and which, dissolved in water, forms liquid ammonia—is itself a compound of nitrogen (or azote), and 17 : 64 of hydrogen by weight, in 100 parts.

When the products which come over in distillation are partly liquid and partly gaseous, the apparatus is arranged as in fig. 5. The beak of the retort *a* is inserted in the tubulated balloon *b*, which communicates with the three-necked bottle *c*, by means of the connecting tube *f*, the descending ends of which are of equal length, and enter only within the necks of *b* and *c*. In one of the necks of the bottle *c* is introduced the safety-tube *e*, made to dip only a little way into the contained liquid, to shut out the air during the distillation. The third neck of *c* communicates with a second bottle *d*, by another connecting tube *g*, one end of which is made long enough to descend almost to the bottom of the bottle *d*, while the other end only enters the neck of *c*.—When necessary, a third bottle, or any number, may be joined to the series in the same manner.

When the apparatus is thus arranged, the balloon *b* is left empty, water is introduced into the first bottle *c*, high enough to cover the orifice of the safety-tube, and also into the second and third bottles, but in greater quantity, to absorb the gas when it passes over. What passes in distillation in the liquid form, collects in the bottom of the balloon; but the gaseous fluid carrying with it the common air out of the apparatus, passes on through the connecting-tube *f*, into the bottle *c*, and thence through the tube *g* into the bottle *d*,—the gas in its passage combining with the water in *c* and *d*. When the operation is finished, the liquid product is found in the balloon, and the gas combined with the water in the second bottle—and also in the third, fourth, &c. when the process requires so many. The bottle *d* might communicate directly with the balloon, without the intervention of the bottle *c*, in the same manner as it now communicates with *c*; but the safety-tube *e* in the latter is of great use, as it not only serves to indicate the progress of the operation, but answers another purpose. It is hardly possible to prevent a partial vacuum from being formed in the retort towards the close of the distillation, either from accidental cooling, or from the production of gas or vapour beginning to slacken, and its consequent contraction in bulk by cooling. This causes a similar vacuum to be formed in the balloon, to fill which, a strong suction or absorption of the liquid from the first bottle, (which, in the case we allude to, would be *d*), would take place through the connecting-tube, causing therein a vacuum, which, in like manner, would produce a similar effect on the one next to it, and so through the whole series of connected bottles; and the different products, in the different bottles, would thus come to be mixed. But this mischief is obviated by the employment of Woulfe's intermediate bottle *c*, with the safety-tube *e*; for the external air pressing on the small column of water in the safety-tube, and displacing it, enters the bottle, and destroys the vacuum.

This tube answers yet another good end. If the gas be liberated too quickly to be easily passed over by the connecting-tubes, it then presses the surface of the liquid contained in *e*, which finding a passage up through the tube *e*, is thereby expelled, and a rupture of the apparatus is prevented. This waste, however, should be as much as possible prevented; for which purpose the upper end of the safety-tube may be introduced into a funnel, by being passed through a perforated cork in the pipe thereof.

WRECK, the ruins of a ship which has been stranded, or dashed to pieces on a shelf, rock, or lee-shore, by tempestuous weather, or by accident.

WRECK is also the name of a soft slippery marine plant that grows on the rocks, having leaves somewhat resembling those of the oak. In many places it is used as manure, but in others being burnt, the ashes make a kind of soda or potash, found valuable in the manufacture of glass.

WREN, SIR CHRISTOPHER, an eminent English philosopher and mathematician, and one of the most learned and celebrated architects of his age, was born at Knole, in Wiltshire, in 1632. In 1660, he invented a method for the construction of solar eclipses; and in the latter part of the same year, he, with ten other gentlemen, formed themselves into a society, to meet weekly, for the improvement of natural and experimental philosophy, being the foundation of the Royal Society; of which learned body he was chosen president in 1680. He died in 1723, at 91 years of age.

WRIGHT, EDWARD, an English mathematician, was born in Norfolk about the middle of the 16th century, and died in 1615. He was one of those who laboured to bring the logarithmic tables of Napier and Briggs to perfection, and was the inventor of that division of the meridian on which the mercator's sailing is founded. He was also the author of two works of navigation, the one entitled, "The Correction of certain Errors in Navigation," published in 1599; and the other entitled "The Harve-finding Art," of which the date is not mentioned.

WRING (To) A MAST, is to bend or strain it out of its natural position, by setting the shrouds up too taut. This phrase is also applied to a capstan, &c. when by too great a strain the component parts of the wood become deranged, and are thereby disunited.

WRING Bolts, are bolts used by shipwrights to bend and secure the planks against the timbers, till they are properly fastened by bolts, spikes, and tree-nails.

WRING-Staves, bars of wood, used with the preceding article. **WRIT**, is the king's precept by which any thing is commanded touching a suit or action: as the defendant or tenant to be summoned, a distress to be taken, a disclaim to be redressed, &c. And these writs are diversely divided; some, in respect of their order or manner of granting, are termed original, and some judicial.

WRIT of Inquiry of Damages, a judicial writ that issues out to the sheriff, upon a judgment by default, in action of the case, covenant, trespass, trover, &c. commanding him to summon a jury to inquire what damages the plaintiff has sustained, occasione præmissorum; and when this is returned with the inquisition, the rule for judgment is given upon it; and if nothing is said to the contrary, judgment is thereupon entered.

WRITER of the Tallies, an officer of the exchequer, being clerk to the auditor of the receipt, who writes upon the tallies the whole of the letters upon the teller's bill.

WRITERS to the Signet. In the Scotch law, attorneys or solicitors who conduct causes before the courts of Edinburgh. They were so called at first from their having the exclusive privilege of preparing papers requiring the king's signet.

WRONG STAMP. By 37 George III. c. 136, any instrument (except bills of exchange, promissory notes, or other notes, drafts, or orders) liable to stamp duty, whereon shall be impressed any stamp of a different denomination, but of an equal or greater value than the stamp required, may be stamped with the proper stamp after the execution, on payment of duty and five pounds penalty, but without any allowance for the wrong stamp. Likewise any such instrument (except as aforesaid) being engrossed without having been first stamped, or having a stamp thereon of less value than required, the same may be stamped after the execution, on payment of the duty and ten pounds penalty only, for each skin thereof; but in case it shall be satisfactorily proved to the commissioners of stamps, that the same hath been so engrossed either by accident or inadvertency, or from urgent necessity, or unavoidable circumstances, and without any intention of fraud, the commissioners are authorized to stamp the same within sixty days after the execution, to remit the penalty in part, or wholly, and to indemnify persons so engrossing the same.

X.

X, or **X**, the twenty-second letter of our alphabet. In numerals it expresses 10, whence in old Roman manuscripts it is used for denarius; and, as such, seems to be made of two **V**'s placed one over the other. When a dash is added over it, thus **X**, it signifies ten thousand.

XEBEC, a small three-masted vessel, navigated in the Mediterranean sea, and distinguished from other European vessels by the great projection of the prow and stern beyond the out-water and stern-post respectively. The sails are in general similar to those of the polacre, but the hull is different. Being generally equipped as a corsair, it is constructed with a narrow floor, to be more swift in pursuit of the enemy; and of a great breadth, to enable her to carry a considerable force of sail for this purpose, without danger of overturning. As these vessels are usually very low built, their decks are formed with a great convexity from the middle of their breadth towards their sides, in order to carry off the water which falls aboard more readily by their scuppers. But as this convexity would render it difficult to walk thereon at sea, particularly when the vessel rocks by the agitation of the waves, there is a platform of grating extending along the deck from the sides of the vessel towards the middle, whereon the crew may walk dry-footed whilst the water is conveyed through the grating to the scuppers. When a xebec is equipped for war, she is occasionally navigated in three different methods, according to the force or direction of the wind. Thus, when the wind is fair, and nearly astern, it is usual to extend square sails upon the main-mast, and indeed, frequently on the fore-mast; and as those sails are rarely used in a scant wind, they are of an extraordinary breadth. When the wind is unfavourable to the course, and yet continues moderate, the square yards and sails are removed from the masts, and laid by in order to make way for the large lateen yards and sails, which soon after assume their place; but if the foul wind increases to a storm, these latter are also lowered down and displaced, and small lateen yards, with proportionable sails, are extended on all the masts. The xebecs, armed as vessels of war by the Algerines, mount from 16 to 24 cannon, and carry from 300 to 450 men, two-thirds of whom are commonly soldiers. The method of working these vessels

is so exceedingly complicated and difficult, that the labour is considerable.

XIPHIAS, the *Sword Fish*, in Natural History, a genus of fishes, of the order apodes. There are three species: The common sword-fish, of the length of twenty feet, which is particularly distinguished by its upper jaw being stretched to a considerable distance beyond the lower, flat above and beneath, but edges at the sides, and of a bony substance, covered by a strong epidermis. It is a fish extremely rapacious, and finds in the above instrument a weapon of attack and destruction, able to procure it the most ample supplies. It first transfixes its prey with this snout, and then devours it. It is found in the Mediterranean, chiefly about Sicily, and is used as food by the Sicilians, who preserve it for a long time by salting it in small pieces.—The broad-finned sword-fish, is found in the northern Atlantic and Indian seas, and is considered as one of the most fatal enemies of the whale tribe. Its strength is so great, that it is said to have pierced with its snout, or sword, the plank of an East Indiaman; and a plank and snout, in attestation of this circumstance, the latter closely driven into the former, are to be seen in the British Museum, having been communicated to Sir Joseph Banks by an East India captain of honour and veracity. When young, this fish is used for food.—The European sword-fish, is known by having its upper jaw lengthened into a hard and sword-shaped blade; and its dorsal fin long, and lowest in the middle. These fish are of steel-blue colour, and measure from fifteen to twenty feet in length. They are found in most of the European seas. By the ancient Romans, sword-fish were highly esteemed as food; and were killed with harpoons by persons stationed in boats for that purpose. They were not only eaten fresh, but cut into pieces and salted. In several places near the Mediterranean, the fins are salted, and sold under the name of *callo*.

XIPHIAS, in Astronomy, the *Dorado*, or *Sword Fish*. See CONSTELLATION.

XIPHIAS is also a term used to express a fiery meteor, that is said to appear in the form of a sword; and which is sometimes called *Acontias*, from its resemblance to a serpent thus denominated in Calabria and Italy, where it is well known.

Y.

Y A R

Y A R

Y, the twenty-third letter of our alphabet. **Y** is a numeral, signifying 150, or, according to Baronius, 159; and with a dash at top, as **Y**, it signifies 150,000.

YACHT, a vessel of state, usually employed to convey princes, ambassadors, or other great personages, from one kingdom to another. As the principal design of a yacht is to accommodate the passengers, it is usually fitted with a variety of convenient apartments, with suitable furniture. The royal yachts are commonly rigged as ketches, except the principal one, which is equipped as a ship. They are commanded by post-captains of the navy. The smaller yachts, which are rigged as sloops, are destined for the use of the commissioners of the navy, &c. Private pleasure boats, when sufficiently large for a sea voyage, are also termed yachts.

YANOLITE. Axinite.

YARD, a long piece of timber suspended upon the masts of a vessel, to extend the sail to the wind. They are either square, lateen, or lug-sail; the first are suspended across the mast at right angles, and the two latter obliquely. The square yards are of a cylindrical form, tapering from the middle, which is

called the slings, towards the extremities, which are termed the yard-arms, and the distance between the slings and the yard-arms on each side, is by the artificers divided into quarters, which are distinguished into the first, second, and third quarters, and yard-arms. The middle quarters are formed into eight squares, and each of the end parts is figured like the frustrum of a cone. All the yards of a ship are square, except that of the mizzen. The proportions for the length of yards, according to the different classes of ships in the British navy, are as follow:—

1000 : gun deck : :	{	560 :	{	Main yard	{	100 Gun.
		559 :				90, 80
		570 :				70
		576 :				60
		575 :				50
1000 : main yard : :	{	561 :	{	fore yard	{	44
		880 :				100, 90, 80,
		874 :				all the rest.

To apply this rule to practice, suppose the gun-deck 144 feet; the proportion for this length is, as 1000 to 575, so is 144 to 83,

which will be the length of the the main yard in feet, and so of all the rest.

1000 : main yard ::	{	820 :	{	mizzen yard	{	100, 90, 80
		847 :				60, 44
		840 :				70
1000 : main yard ::	{	726 :	{	main top sail yard	{	24
		720 :				all the rest.
		719 :				70
1000 : fore yard ::	{	726 :	{	fore top sail yard	{	24
		715 :				all the rest.
		690 :				all the rates.
1000 : main top sail yard ::	{	696 :	{	fore top gallant yard ..	{	70
		690 :				all the rest.
		768 :				70
1000 : fore top sail yard ::	{	750 :	{	mizzen top gallant yard	{	all the rest.

Cross-jack and sprit-sail yards equal to the fore-top sail-yard. Sprit-sail top-sail yard equal to the fore-top-gallant yard. The diameters of the yards are in the following proportions to their length:—The main and fore yards, five-sevenths of an inch to a yard. The top-sail cross jack and sprit-sail yards, nine-fourteenths of an inch to one yard. The top-gallant, mizzen-top-sail, and sprit-sail top-sail yards, eight-thirteenths of an inch to one yard. The mizzen-yard, five-ninths of an inch to one yard. All studding-sails, booms, and yards, half an inch to one yard in length. The large lateen yards are usually composed of several pieces fastened together by woodings, which also serve as steps, whereby the sailors climb to the peak or upper extremity, in order to furl or cast loose the sail. The mizzen yard of a ship, the main yard of a bilander, and the yards of a lugger, though they are not, strictly speaking, lateen sails, are nevertheless hung obliquely on the mast, and the slings are nearer the fore-end than the aftmost end or peak.

YARD Tackles, strong tackles suspended from the main and fore-yards of a ship of war, &c. whereby, with the assistance of the stay-tackles, the boats and other weighty matters are hoisted in and out.

To Brace the YARDS, to traverse them about the masts so as to form greater or lesser angles with the ship's length. See the article **BRACE**.

YARD Arm, is that half of the yard that is on either side of the mast, when it lies athwart the ship.

Yard-Arm and Yard-Arm, a phrase applied to two ships, when they are so near, that their yard-arms nearly touch each other.

YARD-Arm Pieces, pieces of timber kept in readiness to repair the yard-arms in the event of their being carried away or broken.

YARDS, also denote places belonging to the navy, where the ships of war, &c. are laid up in harbour. There are belonging to his majesty's navy, six great yards, viz. Chatham, Deptford, Woolwich, Portsmouth, Sheerness, and Plymouth; these yards are fitted with several docks, wharfs, launches, and graving places; for the building, repairing, and cleaning of his majesty's ships; and therein are lodged great quantities of timber, masts, planks, anchors, and other materials: there are also convenient store-houses in each yard, in which are laid up vast quantities of cables, rigging, sails, blocks, and all other sorts of stores, needful for the royal navy.

YARD, an English measure of length, and used also by several other European nations. The English yard contains 3 feet, and is equal

- to 4-5ths of the English ell,
- to 7-9ths of the Paris ell,
- to 4-3ds of the Flemish ell,
- to 56-5ths of the Spanish vasa or yard.

YARN, wool or flax spun into thread, of which cloth is made; or, in a nautical sense, it signifies one of the threads of which ropes are composed. The thread, or twisted line of hemp, is the first and principal part of a rope. A number of these are twisted together to form a strand, in proportion to the size of the rope whereof the strand makes a part. Three strands are then twisted into one another, which completes the process of ordinary rope-making. But cables, hawsers, and other ground tackling, are composed of three strands, each of which is formed by three lesser ones. See **CABLE**.

Yarn is ordered after the following manner: After it has been spun upon spindles, spools, or the like, they wind it upon recks which are hardly two feet in length, and have but two contrary cross bars, being the best and the least liable to raveling. In reeling of yarn, the better to keep it from fine raveling, you must, as it is reeled, with a by-band of big twist, divide the slipping or skein into several leys, allowing to every ley eighty threads, and twenty leys to every slipping, if the yarn is very fine, otherwise less of both kinds. The yarn being spun, reeled, and in the slipping, the next thing is to scour it. In order to fetch out the spots, it should be laid in lukewarm water for three or four days, each day shifting it once, wringing it, out and laying it out in another water of the same nature; then carry it to a well or brook, and rinse it till nothing comes from it but pure clear water; that done, take a bucking-tub, and cover the bottom thereof with very fine ashen ashes; and then having opened and spread the slippings, covering them with ashes as before, and thus laying one upon another till all the yarn be put in, afterwards cover the uppermost yarn with a bucking-cloth, and in proportion to the bigness of the tub lay therein a peck or two more of ashes: this done, pour upon the uppermost cloth a great deal of warm water till the tub can receive no more, and let it stand so all night. Next morning you are to set a kettle of clean water on the fire, and when it is warm pull out the spigot of the bucking-tub, to let the water run out of it into another clean vessel. As the bucking-tub wastes, fill it up again with the warm water on the fire; and as the water on the fire wastes, so likewise fill that up with the ley that comes from the bucking-tub, ever observing to make the ley hotter and hotter till it boils; then you must, as before, ply it with the boiling ley, at least four hours together, which is called the driving of a breck of yarn. Of yarn thus prepared, are made the sails, cloths, &c. used in vessels.

YARN-Mill. This machine may be worked by water, or as a horse-mill, or in any other way, and is made and used in the following manner. There is a cylinder marked A, plate *Ward*, &c. fig. 1, three feet diameter, and ten inches broad, made of dry wood or metal, turned true, and covered on its circumference with a smooth leather, upon which are placed the rollers marked D, covered with leather, and supported in their situations by the slits in the covered piece of wood marked K, in which the iron axes of the rollers turn, but suffers them to press on the wheel marked A. There must be another piece similar to the above, to support the other end of the rollers. These rollers are of different weights. The upper roller marked D I is two stone, the rest decreasing to the last, which is only two pounds weight and one half. There is an iron fluted roller marked F, furnished with a toothed wheel at each end, and a wood one, marked G, covered with cloth, and over it a smooth leather. There is an assisting roller, marked H, of fluted iron. These rollers are supported by their axes turning in the slit, marked 2, of the piece of wood, marked M, fig. 3, which is here separated from the end of the frame marked S, to shew the rollers and wheel-work. The rollers marked G and F are squeezed together by means of the lever marked p, and its weight marked w, fig. 3. The roller marked H is pressed to the mark G, by its axis acting upon the inclined plane marked x, fig. 3. There is a rubbing roller covered with woollen cloth, and on its axis is a small wheel marked I, driven by the wheel marked S. This roller rests upon the roller marked G, and by its motion prevents any dirt or fibres from adhering to it. There is a cloth, marked N, revolving over two rollers marked O, O, which has motion given it from the wheel marked C, by means of another wheel marked P. This cloth moves at the same rate as the surface of the wheel marked A. There is a supporter marked Y, of the axis of the wheel marked O, P, but is removed, in order to shew them; it is fixed by its tenons in the mortises, marked Z, Z. The roller marked B is kept in action by its endeavour to slip down the inclined plane at the top of the piece marked Y, thereby pressing against the revolving cylinder; and another piece similar to this, must be understood to support the other end of the roller's axis. By the side of this revolving cloth is a table placed, of the same length and breadth as the cloth is, to which belong two smooth cloths or leathers, of the same size as the table. The machine being thus prepared, the attendant or workman must take a quantity of hemp, tow,

flax, or wool, more or less, according to the fineness of the thread to be made, and lay or spread it evenly upon one of the smooth cloths on the table, then place it on the revolving-wheel marked N, motion being communicated to the roller marked T, by wheel-work as usual, from a water, horse, or other kind of mill, which wheel-work is communicated to the wheel marked Q, on whose axis is a nut, which turns the wheel marked C; and thereby the cylinder marked A moves, and with it all the rollers; by which motion the hemp, tow, flax, or wool is drawn forward. The cloth turns down, but the hemp, tow, flax, or wool, go upon the cylinder marked A, under the roller marked B, and so forward under the rollers marked D, then falls in between the rollers marked G, F, turns under the roller marked G, and over the roller marked H, which, as it gives the rollers hold of the hemp, tow, flax, or wool, in two places, enables them to draw forward the long fibres thereof, though many of them are to draw from under the marks 4 or 5 of the pressing-rollers marked D, it then falls into a canister marked R, and as by the wheel-work the rollers marked F, G, H, move three times faster than the cloth and cylinder, the sliver must be three times longer than when presented. By the time this is drawing, the other cloth is filled with hemp, tow, flax, or wool, as before, and laid upon the revolving roller, laying the hemp, tow, flax, or wool, over the end of the other which goes forward as before, and thus a continued sliver is produced as long as the machine continues its motion. But in order that this sliver may come out of the canister marked R, without entanglement, it must pass through an instrument marked 5, fig. 3, placed over the rollers marked F, G, its open side marked T, to the cylinder at mark 4, supported by its ends marked V, V, in the slit marked W, of the before-described pieces marked K. The aperture X is so small as to press the fibres close to each other in their passage through it previous to their passing the rollers, by which means they remain pressed side by side in the sliver, and will not entangle. These thick slivers are drawn smaller by a similar process, and in the same manner are used for cottons: but the machines for drawing are all of the same structure as the above, except that they have no revolving cloth. The sliver is applied to the cylinder under the roller marked B, which draws it forward under all the rollers as before described, drawing it out, or lengthening it, every fresh machine through which it presses, till it be small enough for the spinning machine. It must be remarked, that the cylinders are made less in diameter, according to the different smallness of the sliver intended to be drawn upon them at the first; whilst the sliver is at its greatest thickness, the cylinder is required to be three feet diameter as above described, the next rather less, and so on to the last, which is only two feet. The aperture of the bottom of the contractor belonging to each machine is also made one-third part smaller than another in succession, from the greatest to the smallest cylinder; as also the drawing rollers marked F, G, H, are furthest from the pressing-roller marked D, in the longest cylinder, and nearest at the smaller cylinder. At the largest cylinder the distance is about nine inches, and the smallest about four inches; but their distance cannot in all cases be fixed, as it depends on the different lengths of the slivers of the hemp, tow, flax, or wool; long ones requiring the distances mentioned, and short ones requiring the distances much shorter than is here specified.

The following several letters or marks are in the machine figured 2. The spinning machine, as to its drawing principle, is the same as the drawing machine. The slivers are presented to it in canisters marked A, and drawn over a cylinder marked B covered with rollers marked D. The fibres which are to form the thread are drawn from the cylinder by the rollers marked C, the under roller of which is made of fluted iron, the other of wood, covered with leather; they move six or eight times faster than the cylinder marked B are enabled to draw the hemp, tow, flax, or wool, forward from under the pressing-rollers marked D, by being squeezed together with the weights and crooks marked a, a, looked to the small part of the rollers marked C. There is a belt of smooth cloth marked E, moving on two rollers, which are turned by the wheel marked F, on the axis of the fluted roller; at the opposite end of which, as at the mark G, is a nut, which turns the wheel marked H, on whose axis is another nut, turning the wheel marked I, and

thereby the cylinder marked B, with all its rollers. These rollers move in curved pieces of wooden metal, marked K, which, to prevent confusion, are not represented in their places; they have slits in them in which the rollers' axes are guided, but so deep as at all times to suffer the rollers to press upon the cylinder. These rollers are covered with cloth and leather. The top roller is about ten pounds weight, decreasing to the sixth roller, which is only about one pound weight: the yarn is turned by the spindles marked L, and rubbed over the wet cloth belt if spinning linen yarn, but if spinning worsted yarn the belt must be removed, that it may not touch it as it passes to the spool, which it coils round as fast as the rollers let it out. The spindles marked C are turned by a bolt from the wheel marked M, which derives its motion from the mill, and by a wheel on its axis communicates it to the roller under the mark C by the wheel marked F, and so to the rest, as above described. The hemp, tow, flax, or wool, is twined in the same manner as cotton is by mills.

YAW, the movement by which a ship deviates from the line of her course towards the right or left in steering.

YAWL, a boat usually rowed with four or six oars. See the article **Boat**.

YEAR, in Astronomy and Chronology, the portion of time occupied by the sun in passing over the twelve signs of the zodiac, and in which is comprehended the several changes of the seasons. The mean solar year, according to the observations of the best modern astronomers, contains 365 days, 5 hours, 48 minutes, 48 seconds; the quantity assumed by the authors of the Gregorian calendar, is 365 days, 5 hours, 49 minutes; but in the civil or popular account the year contains 365 days, 6 hours, or rather 365 days for three years in succession, and every fourth year 366 days. See **BISSEXTILE**.

The vicissitude of seasons seems to have given occasion to the first institution of the year. Man, naturally curious to know the cause of their diversity, soon conjectured that it depended upon the motion of the sun, and therefore gave the name year to the space of time in which that luminary seemed to perform his whole course, by returning again to the same point of its orbit. According to the accuracy of their observations, the year of some nations was more perfect than that of others, but none of them quite exact, nor whose parts did not shift with regard to the parts of the sun's course.

According to Herodotus, it was the Egyptians who first formed the year, making it to consist of 360 days, which they subdivided into 12 months, of 30 days each. Mercury Trismegistus added five days more to the account; and which form of the year, Thales is said to have instituted amongst the Greeks; and hence, with successive improvements, it has been handed down to the moderns.

The **Solar YEAR**, is either astronomical or civil.

The **Astronomical Solar YEAR**, is that which is precisely determined by astronomical observations, and is of two kinds, *tropical*, and *sidereal* or *astral*.

Tropical or **Natural YEAR**, is the time which the sun, or rather the earth, employs in passing through the 12 signs of the zodiac, and which, as stated above, contains 365 days, 5 hours, 48 minutes, 48 seconds, which is the only natural year, because it always keeps the same seasons in the same months.

Sidereal YEAR, or **Astral Year**, is the space of time the sun takes in passing from any fixed star, till his return to it again. This consists of 365 days, 6 hours, 9 minutes, 11 seconds, being 20 minutes, 29 seconds longer than the true solar year.

Anomalistic YEAR, is the interval which is occupied by the sun in passing from apogee to apogee, or from perigee to perigee: it is greater than the sidereal year by the time required to describe the annual progression of the apogee. The length of the anomalistic year is 365 days, 6 hours, 14 minutes, 1 second.

Lunar YEAR, is the space of 12 lunar months. Hence, from the two kinds of synodical lunar months, there arise two kinds of lunar years; the one astronomical, the other civil.

Lunar Astronomical YEAR, consists of 12 lunar synodical months; and therefore contains 354 days, 8 hours, 48 minutes, 38 seconds, and is therefore 10 days, 21 hours, 0 minutes, 10 seconds, shorter than the solar year. A difference which is the foundation of the epact.

Lunar Civil YEAR, is either the common or embolismic.

The **Common Lunar YEAR**, consists of 12 lunar civil months; and therefore contains 354 days. And

The **Embolic, or Intercalary Lunar YEAR**, consists of 13 lunar civil months, and therefore contains 384 days.

Thus far we have considered years and months with regard to astronomical principles, upon which the division is founded. By this, the various forms of civil years that have formerly obtained, or that do still obtain, in divers nations, are to be examined.

Civil YEAR, is that form of the year which every nation has contrived or adopted for computing their time by. Or the civil is the tropical year, considered as only consisting of a certain number of whole days: the odd hours and minutes being set aside, to render the computation of time, in the common occasions of life, more easy. As the tropical year is 365 days, 5 hours, 49 minutes, or almost 365 days, 6 hours, which is 365 days and a quarter; therefore, if the civil year be made 365 days, every fourth year it must be 366 days, to keep nearly to the course of the sun. And hence the civil year is either common or bissextile.

Common Civil YEAR, is that consisting of 365 days; having seven months of 31 days each, four of 30 days, and one of 28 days; as indicated by the following well-known memorial verse:—

Thirty days hath September,
April, June, and November;
February twenty-eight alone,
And all the rest have thirty-one.

Bissextile, or Leap YEAR, contains 366 days, having one day extraordinary, called the intercalary, or bissextile day, and takes place every fourth year. This additional day to every fourth year was first introduced by Julius Cæsar, who, to make the civil years keep pace with the tropical ones, contrived that the six hours which the latter exceeded the former should make one day in four years, and be added between the 24th and 23d of February, which was their 6th of the calends of March; and as they then counted this day twice over, or had *bis sexto calendas*, hence the year itself came to be called *bis sextus*, and *bissextile*. However, among us, the intercalary day is not introduced by counting the 23d of February twice over, but by adding a day at the end of that month, which therefore in that year contains 29 days. A farther reformation was made in the civil year by pope Gregory.

The civil or legal year, in England, formerly commenced on the day of the Annunciation, or 25th of March; though the historical year began on the day of the circumcision, or 1st of January; on which day the German and Italian year also begins. The part of the year between these two terms was usually expressed both ways; as 1745-6, or 1744. But by the act for altering the style, the civil year now commences with the 1st of January.

Ancient Roman YEAR. This was the lunar year, which, as first settled by Romulus, contained only ten months, of unequal numbers of days, in the following order, viz.:—March 31; April 30; May 31; June 30; Quintilis 31; Sextilis 30; September 30; October 31; November 30; December 30; in all 304 days; which came short of the true lunar year by 50 days, and of the solar by 61 days. Hence, the beginning of Romulus's year was vague, and unfixed to any precise season; to remove which inconvenience, that prince ordered so many days to be added yearly as would make the state of the heavens correspond to the first month, without calling them by the name of any month. Numa Pompilius corrected this irregular constitution of the year, composing two new months, January and February, of the days that were to be added to the former year. Thus Numa's year consisted of 12 months, of different days, as follow, viz.:—

January 29;	- -	February 28;	- -	March 31;
April 29;	- -	May 31;	- -	June 29;
Quintilis 31;	- -	Sextilis 29;	- -	September 29;
October 31;	- -	November 29;	- -	December 29;

in all 365 days; therefore exceeding the quantity of a lunar civil year by one day; that of a lunar astronomical year by 15 hours, 11 minutes, 22 seconds; but falling short of the com-

mon solar year by 10 days, so that its beginning was still vague and unfixed. Numa, however, desiring to have it begin at the winter solstice, ordered 22 days to be intercalated in February every second year, 23 every fourth, 22 every sixth, and 23 every eighth year. But this rule failing to keep matters even, recourse was had to a new way of intercalating; and instead of 23 days every eighth year, only 15 were to be added. The care of the whole was committed to the pontifex maximus; who, however, neglecting the trust, let things run to great confusion. And thus the Roman year stood till Julius Cæsar reformed it.

The **Ancient Egyptian YEAR**, called also the year of Nabonassar on account of the epocha of Nabonassar, is the solar year of 365 days, divided into 12 months of 30 days each, besides five intercalary days added at the end. The names, &c. of the months are as follows:—1. Troth. 2. Paophi. 3. Athyr. 4. Chojac. 5. Tybi. 6. Mecheir. 7. Phamenoth. 8. Pharmuthi. 9. Pachon. 10. Pauni. 11. Epiphis. 12. Mesori; beside the ἡ μεραι επαγομεναι.

The **Ancient Greek YEAR**, was lunar; consisting of 12 months, which at first had 30 days apiece, then alternately 30 and 29 days, compared from the first appearance of the new moon; with the addition of an embolismic month of 30 days every 3d, 5th, 8th, 11th, 14th, 16th, and 19th year of a cycle of 19 years; in order to keep the new and full moons to the same terms or seasons of the year. Their year commenced with that new moon, the full moon of which comes next after the summer solstice. The order, &c. of their months was thus:—

1. Εκατομβαιων, containing 29 days. 2. Μηταγίτων, 30. 3. Βοηδρομιων, 29. 4. Μαεμακτηριων, 30. 5. Πυανεψιων 29. 6. Ποσειδεων, 30. 7. Γαμηλιων, 29. 8. Αεθερσιων, 30. 9. Ελαφηβολιων, 30. 10. Μενυχιων, 30. 11. Θαρρηλιων, 29. 12. Σκιροφιων, 30.

The **Ancient Jewish YEAR**, is a lunar year, consisting commonly of 12 months, which alternately contain 30 and 29 days. It was made to agree with the solar year, either by the adding of 11, and sometimes 12 days, at the end of the year, or by an embolismic month. The names and quantities of the months stand thus:—1. Nisan, or Abib, 30 days. 2. Jiar, or Zius, 29. 3. Siban, or Siwan, 30. 4. Thammuz, or Tammuz, 29. 5. Ab, 30. 6. Elul, 29. 7. Tisri, or Ethanim, 30. 8. Marchesvan, or Bull, 29. 9. Cisleu, 30. 10. Tebeth, 29. 11. Sabat, or Schebeth, 30. 12. Adar, in the embolismic year, 30. Adar, in the common year, was but 29. Note, in the defective year, Cisleu was only 29 days; and in the redundant year, Marchesvan was 30.

The **Persian YEAR**, is a solar year of about 365 days, consisting of 12 months of 30 days each, with five intercalary days added at the end.

The **Arabic, Mahometan, and Turkish YEAR**, called also the year of the Hegira, is a lunar year, equal to 354 days, 8 hours, and 48 minutes, and consists of 12 months, which contain alternately 30 and 29 days.

The **Hindoo YEAR** differs from all these, and is indeed different in different provinces of India. The best account that we have of it is by Mr. Cavendish, in the Philosophical Transactions of the Royal Society for the year 1792.

YEAR and Day, is a time that determines a right in many cases; and in some works an usurpation, and in others a prescription; as in case of an estray, if the owner, proclamation being made, challenges it not within the time, it is forfeited. So is the year and day given in case of appeal; in case of descent after entry or claim, if no claim upon a fine or writ of right at the common law; so of a villain remaining in ancient demesne; of a man sore bruised or wounded; of protections; essoins in respect of the king's service; of a wreck; and divers other cases.

YEAR DAY AND WASTE, is a part of the king's prerogative, whereby he challenges the profits of their lands and tenements for a year and a day, that are attainted of petty treason or felony, whoever is lord of the manor where the lands or tenements belong; and not only so, but in the end may waste the tenements, destroy the houses, root up the woods, gardens, and pasture, and plough up the meadows, except the lord of the fee agrees with him for redemption of such waste, afterward restoring it to the lord of the fee.

YEARS, ESTATE FOR. Tenant for term of years, is where a man lets lands or tenements to another, for a certain term of years agreed upon between the lessor and lessee; and when the lessee enters by force of the lease, then he is tenant for term of years.

YEAST, is the barm or froth which rises in beer, and other malt liquors, during a state of fermentation. When thrown up by one quantity of malt or vinous liquid, it may be preserved, to be put into another at a future period, on which it will exert a similar fermentative action. Yeast is likewise used in the making of bread, which without such an addition would be heavy and unwholesome.

YELLOW, NAPLES, a fine pigment, so called from the city in which it was long prepared.

YEOMAN, is defined to be one that has fee land of 40s. a year; who was thereby heretofore qualified to serve on juries, and can yet vote for knights of the shire, and do any other act where the law requires one that is *probus et legalis homo*.

YEOMAN, an inferior officer under the boatswain, gunner, or carpenter of a ship of war, and usually charged with the stowage, account, and distribution of their respective stores.

YEOMAN of the Guard, one belonging to a sort of foot guards, who attend at the palace. The yeomen were uniformly required to be six feet high. They are in number 100 on constant duty, and 70 off duty. The one half carry arquebuses, and the other pertuisans. Their attendance is confined to the sovereign's person, both at home and abroad. They are clad after the manner of king Henry VIII.

YOKE, in Agriculture, a frame of wood fitted over the necks of oxen, whereby they are coupled together, and harnessed to the plough.

YOKK, a small board which crosses the upper end of a boat's rudder at right angles, and having two lines extending from its opposite extremities to the stern-sheets of the boat, whereby she is steered as with a tiller.

YOLK, is an animal soap, the natural defence of the wool of sheep. In washing sheep, the use of water containing the carbonate of lime should be avoided; for this substance decomposes the yolk of the wool, and wool often washed in calcareous water becomes rough and more brittle. The finest wool, such as that of the Spanish and Saxon sheep, is most abundant in yolk. M. Vanquelin has analyzed several different species of yolk, and has found the principal part of all of them a soap, with a basis of potassa (i. e. a compound of oily matter and potassa,) with a little oily matter in excess.

YOLK is also the yellow substance found in the middle of an egg, by which the chicken is supported before its exclusion from the shell; and even afterwards, a portion being received into its belly, it is its only source of nourishment for a considerable time.

YOUNKER, a general name for a stripling in the service.

YTTRIA. This is a new earth, discovered in 1794, by Prof. Gadolin, in a stone from Ytterby in Sweden. Yttria is perfectly white when not contaminated with oxide of manganese, from which it is not easily freed. Its specific gravity is 4.842. It has neither taste nor smell.

Z.

Z E R

Z, the twenty-fourth and last letter of our alphabet. In abbreviations this letter formerly stood as a mark for several sorts of weights; sometimes it signified an ounce and a half, and very frequently it stood for half an ounce; sometimes for the eighth part of an ounce, or a dram troy weight; and has in earlier times been used to express the third part of an ounce, or eight scruples. ZZ were used by some of the ancient physicians to express myrrh, and at present they are often used to signify sinziber or ginger.

ZAFFRE, is the oxide of cobalt, employed for painting pottery-ware and cobalt of blue colour.

ZEA MAIZE, or Indian Corn, in Botany, a genus of the monocotyledon triandria class and order. Natural order of graminea or grasses. Essential character: males in distinct spikes; calyx, glume two-flowered, awnless: corolla, glume two-flowered: awnless; female, calyx glume one-flowered, two-valved; corolla, glume four-valved; style one, filiform pendulous; seeds solitary, immersed in an oblong receptacle. There is but one species, viz. Z. mays, Indian corn, or maize and several varieties. See MAIZE or MAISE.

ZENITH, an Arabic word, used in astronomy to denote the vertical point of the heavens, or that point directly over our heads. The zenith is called the pole of the horizon, being 90° distant from every point of that circle.

ZENITH Distance, the arc intercepted between any celestial object and the zenith, being the same as the co-altitude of an object.

ZEOLITE. This stone was first described by Cronstedt in the Stockholm Transactions for 1756. It is sometimes found amorphous and crystallized. The primitive form of its crystal is a rectangular prism, whose bases are squares. The most common variety is a long four-sided prism terminated by low four-sided pyramids.

ZERO. The commencement of a scale of the thermometer marked 0. In Fahrenheit's thermometer, zero is 32° below freezing point. In Reaumur's thermometer, and in the centigrade thermometer, zero coincides with the freezing point of water.

Z I N

ZETETIC METHOD, an old term for what we now call analytic method.

ZIMOME. If the gluten of wheat be treated with alcohol, it is reduced by the loss of water and gliadine to one-third of its bulk, which consists of zimome. Zimome is a shapeless mass, rough, and destitute of cohesion. It is heavier than water. It is soluble in vinegar and the mineral acids, at a boiling temperature. Zimome is found in various vegetables.

ZINC, in Chemistry and Mineralogy, a metal unknown to the ancients, though they were acquainted with calamine, one of its ores, and the effect which this had in converting copper into brass. Zinc has usually been ranked among those metals which, from their imperfect ductility and malleability, were long denominated semi-metals. It was known, that by uniform pressure zinc might be extended into thin plates, and, more lately, it has been discovered, that, at a certain temperature, it has so much malleability and ductility that it can be lamellated and drawn into wire.

Zinc is of a white colour with a shade of blue; in a fresh fracture it is possessed of considerable lustre. It is hard, and not easily cut with a knife. The specific gravity is nearly 7.2. The ores of zinc are calamine and blende. Calamine is an oxide, frequently with a portion of carbonic acid: blende is a sulphuret, containing also some iron and other extraneous matters. Zinc is melted by a moderate heat, and the fused mass, on cooling, forms regular crystals. Though scarcely altered by exposure to the air at a low temperature, yet it is rapidly oxidized by one amounting to ignition. When kept in a degree of heat barely sufficient for its fusion, zinc becomes covered with a grey oxide. But when thrown into a crucible or deep earthen pot, heated to whiteness, it suddenly inflames, burns with a beautiful white flame, and a white and light oxide sublimes, having considerable resemblance to carded wool. It is brittle, and has not been applied to any use. Zinc may be combined with mercury, either by triturating the metal together, or dropping mercury into melted zinc. This amalgam is used to rub on electric machines, in order to excite electricity. Zinc combines readily with copper, and forms one of the most useful of all the

metallic alloys. The metals are usually combined together by stratifying plates of copper, and native oxide of zinc combined with carbonic acid, called calamine, and applying heat. When the zinc does not exceed a fourth part of the copper, the alloy is known by the name of brass. It is of a beautiful yellow colour, more fusible than copper, and not so apt to tarnish. It is malleable, and so ductile that it may be drawn out into wire. Its density is greater than the mean. It ought to be by calculation 7.6, but it actually is 8.4 nearly, so that its density is increased by about one-tenth. When the alloy contains three parts of zinc and four of copper, it assumes a colour nearly the same with gold, but it is not so malleable as brass. It is then called pinchbeck, prince's metal, or Prince Rupert's metal. Brass was known and very much valued by the ancients. They used an ore of zinc to form it, which they called cadmia. To brass they gave the name of orichalcum. Their α s was copper, or rather bronze.

ZIRCON, in Mineralogy, the name of a genus containing two species, viz. hyacinth and zircon. It is found commonly in roundish angular pieces, which have almost always rounded angles and edges. Specific gravity about 4.6. The constituent parts are, according to Klaproth,

Zirconia,	69.0
Silica,	26.5
Oxide of iron,	0.5
Loss,	4.0

100.0

ZIRCONIA, was first discovered in the jargon of Ceylon, by Klaproth, in 1789, and it has since been found in the jacinth. Zircon is a fine white powder, without taste or smell, but sometimes harsh to the touch. It is insoluble in water; yet if slowly dried, it coalesces into a semi-transparent yellowish mass, like gum-arabic, which retains one-third its weight of water. It unites with all acids. It is insoluble in pure alkalies; but the alkaline carbonates dissolve it. Heated with the blow-pipe, it does not melt, but emits a yellowish phosphoric light. There is the same evidence for believing that zirconia is a compound of a metal and oxygen, as that afforded by the action of potassium on the other earths.

ZIZANIA, a genus of plants of the class monocœia, order hexandria, and in the natural system arranged under the fourth order graminæ.

ZODIAC, in Astronomy, an imaginary ring or broad circle in the heavens, in form of a belt or girdle, within which the planets all make their excursions. In the very middle of it runs the ecliptic, or path of the sun in his annual course; and its breadth, comprehending the deviations or latitudes of the earlier known planets, is by some authors accounted 16, some 18, and others 20 degrees. The zodiac cutting the equator obliquely, makes with it the same angle as the ecliptic, which is its middle line, which angle, continually varying, is now nearly equal to $23^{\circ} 28'$; which is called the obliquity of the ecliptic, and constantly varies between certain limits which it can never exceed.

The zodiac is divided into 12 equal parts of 30 degrees each, called the signs of the zodiac, being so named from the constellations which anciently occupied them. But the stars having a motion from west to east, those constellations do not now correspond to their proper signs; from whence arises what is called the precession of the equinoxes. And therefore when a star is said to be in such a sign of the zodiac, it is not to be understood of that constellation, but only of that dodecatemery or 12th part of it.

It is a curious fact, that the solar division of the Indian zodiac is the same in substance with that of the Greeks, and yet that it has not been borrowed either from the Greeks or the Arabians. The identity, or at least striking similarity, of the division is universally known; and Montucla has endeavoured to prove that the Bramins received it from the Arabs. His opinion has been very generally admitted; but in the second volume of the Asiatic Researches, Sir William Jones asserts that neither of these nations borrowed that division from the other; that it has been known among the Hindoos from time immemorial; and that it was probably invented by the first progenitors of that race, whom he considers as the most ancient of mankind, before their

dispersion. The Greek zodiac originally contained only eleven signs; the Scorpion in their zodiac occupying the place of two.

The Zodiacs of Emesh and Dendera.—These monuments represent the actual state of the heavens at the solstice period, i. e. the year 2782 B. C., or the year 1322 B. C., or the year 136 A. C. the solstice period being 1460 years.

Received chronology assigns a period of 5824 years from the Creation to 1820 of the Christian era. The Samaritan text of the scriptures makes the world to have been created 6006; the Septuagint 7210 years; and it is 7608 years since the creation, according to the testimony of Josephus. The mean of all these dates will be 6651 years, and which is perhaps not far from truth. If we adopt the chronology of the LXX. the period of 7210, from the creation to the year 1820 of our era, may be divided thus:—2262 years from the creation to the deluge, and 3128 years from the deluge to the birth of our Saviour. With this system of chronology we shall be able to explain consistently the age of these zodiacs.

In the year 4180 of the Julian period, Cambyses conquered Egypt; at the end of 39 years the people revolted; in two years after they were compelled to submit again to their tyrant. Under the reign of Artaxerxes, about 21 years after their first emancipation, they again took arms, and drove the Persians back into Asia; in five years after, they were compelled to receive the law from a Persian satrap; but after an interval of 80 years they revolted a third time, and resisted their invaders for 25 years; at length they yielded; and in the eighteenth year following, Egypt submitted to the arms of Alexander. During these wars the sciences ceased to flourish; priests and learned men were sacrificed by Cambyses; the temples of the gods were defaced, their images mutilated; and if in the most splendid eras of her prosperity the priests of Egypt never imparted their knowledge to the public, there is little ground to suppose that the remnant who guarded its last faint embers would be willing the conquering Greeks should light the torch of science in the dying flame. But when, where, and by whom the severer sciences of geometry and astronomy, as transmitted by the Egyptians to the Greeks, were constructed, is not easy to decide. At some remote period there were mathematicians and astronomers who knew the sun to be the centre of the planetary system, and that the earth, itself a planet, revolves round the central fire; who described the orbits, and calculated the returns of comets; who indicated the number of solar years contained in the great circle, by multiplying a period of 180 years by another period of 144 years; who reckoned the sun's distance from the earth by a measurement equal to 800,000,000 Olympic stadia, and who must therefore have taken the parallax of that luminary by a method little inferior to that now in use, and certainly much more correct than that adopted by Hipparchus; who fixed the moon's distance from the primary planet at 59 semidiameters of the earth; who had measured the circumference of our globe with so much exactness, that their calculations only differed by a few feet from that made by our modern geometricians; who held that the Moon and the other planets were worlds like our own, and that the Moon was diversified by valleys, mountains, and seas; who asserted that there was yet a planet which revolved round the Sun, beyond the orbit of Saturn; who reckoned the planets to be 16 in number; and who calculated the length of the tropical year within three minutes of the true time.—(See Sir W. Drummond's *Essay on the Science of the Egyptians and Chaldeans*.)

Before the deluge, men lived usually 800 or 900 years. In so many years every individual had time to make great progress in knowledge; he could devote whole centuries to any one pursuit; during as many centuries he could verify his experiments; and if a large proportion of society was then raised above the pressure of actual want, the arts and sciences of the descendants of Noah were in all probability as well known in the 2303 years that elapsed between the creation and the deluge, as in a few centuries they have reached so much excellence in modern times.

Indeed, the Jews, Syrians, and Arabians, have numerous traditions of the astronomical knowledge of Adam, Seth, Enosh, and Ham. Seth lived 912 years, and to him the Hebrews ascribe the invention of astronomy. He is the Egyptian Thoth. During 720 years he could observe the stars, which, in

ANCIENT ZODIACS.

The Zodiac of Esne, Latopolis

The Egyptian Zodiac from the ceiling of the Temple of Isis at Dendera

this period, would have moved forwards 10° , or $\frac{1}{4}$ of a sign. The descendants of Noah advanced in different directions from a common centre; hence we find all the Oriental nations in possession of a zodiac with 12 signs, with the exception of the Chaldeans, who were followed in this by the Alexandrian Greeks, who counted only 11, allotting 60° to Scorpius, and not admitting Libra, one common model must have served all these people and nations, for the emblems are all alike, and a single glance at the plate will set this matter at rest. Moreover, the Japetus of the Greeks, father of Altus, who is said to have invented the armillary sphere, is none other than the Hebrew scripture Japhet; and thus the testimony of the Greeks proves, that the immediate descendants of Noah were versant in astronomy, in which it is clear they must have been instructed by the patriarch and his sons.

Though the Chaldeans always divided their zodiac into 11 signs, the Scorpion perhaps occupying two signs, as is alluded to by Ovid, lib. ii. v. 197, Metam.

"Scorpius
Porrigit in spatium signorum membra duorum."

But the Egyptians parcelled it into 12 signs, over which 12 gods presided. "Egyptii," inquit Servius, "*duodecim esse asserunt signa: Chaldaei vero undecim; nam Scorpium et Libram unum signum accipiunt; Chela Scorpii Libram faciunt.*"

Yet, though we ascribe the division of the stars into constellations to the antediluvians, and assign to them the invention of the zodiac, it does not follow that the postdiluvian emblems and signs were identically the same as those which had obtained before the deluge. Amidst these changes, the Egyptians, the descendants of Ham or Cham, having adopted the worship of the host of heaven, would naturally choose such names and symbols as suited their purposes and situation; and while they retained the ancient divisions of the zodiac, they probably altered some of the emblems by which it was represented.

Every thing in the zodiac of Dendera seems to prove that it owed its existence to the natives of the soil, and could not have been constructed in the age of Adrian and Antoninus Pius. The emblems and figures are all Egyptian. There is nothing Greek in the designs. All is Egyptian—astronomy, mythology, symbols, taste, style, manner.

The sun's place in the oblong zodiac of Dendera is indicated at the division of the two scarabæ, or beetles. The small scarabæus is next to Gemini, and the larger scarabæus next to Leo. The former represents the ascending part of the sign Cancer, the latter the descending part of the same sign. The relative proportions of these beetles is as 17 to 13, or perhaps as 16 to 14. We consequently fix the date of this zodiac at the time when the solstitial colure corresponded with the 14th degree of the dodecatemoria of Cancer, according to the real zodiac. This nearly corresponds to the first year of the solstice period of which the Thoth, or beginning, may be fixed for the year 1322 a. c. It is now 2160 years since the sun at the summer solstice quitted the dodecatemoria of Cancer, according to the precession of the equinoxes. And if to these 2160 years we add the 16° of \odot descending, we shall give an existence of 3312 years, at least, to the oblong zodiac of Dendera. The book of Job has a higher antiquity than this, if, as is generally supposed, it was written 1700 years before our æra. Leo, however, was once a solstitial sign; Taurus, then, opened the year. This was 2500 years a. c. The lion Hercules then sprung from Typhon. How did it travel from Egypt to Argolis? Thus:—the Nemean games were celebrated at the season when the sun in his annual course is in the sign of Leo. The *Hercule*, (universal heat) the sun, took possession of the sign Leo, at the period of this annual festival. And why might not an Egyptian colony have settled at Argolis four or five centuries after the deluge? There is no difficulty in giving an affirmative answer, if the chronology of the LXX. be adopted. The Persian symbol of a bee entering the mouth of a lion, commonly known as the Mithraic lion, represents the sun entering Leo; and this symbol may be referred to the period when the sun at the summer solstice was in the first degree of Leo.

The Egyptians began their sacred year with the heliacal rising of Sirius, Siris, or Sothis, the star of Isis. The dog-star

is near Cancer, with which in Egypt it rises cosmically: the Roman year commenced with Aquarius; that of the Egyptians with Cancer. But I here observe, that Soth, a name of the dog-star, was also the name of an Egyptian divinity named Thoth, who also presided over this star; and Thoth seems to be the same with the Seth of scripture.

Oriental scholars interpret Seth *Thoth*, *Shoth*, *Thist*, by *possessit, ponere*; and assert, that Seth, Soth, and Thoth, were only different names for the patriarch whom the Hebrews, Syrians, and Arabians, consider as the institutor of the sciences. Who has not heard of the two columns of stone and brick, erected by the descendants of Seth, and which Josephus pretends to have existed still in the land of Siriad in his time? Manetho, who flourished 300 years before Josephus, says, he took his history from the columns placed in the Siriad land, which had been inscribed in the sacred dialect, and in hieroglyphical characters, by Thoth, the first Hermes, before the deluge! And the Arabians have a tradition, that Hermes, or Thoth, invented his books, or rather tables of brass or stone, in one of the pyramids, before the deluge. Sir W. Drummond thinks *Nubia* was *Siriad*; because the Nile, above Syene, was called *Siri*, or *Siris*. Perhaps the name of Seth, which the Egyptians corrupted into Thoth, which signifies the *basis*, and which, as a proper name, might indicate him who first established the civil year, was given to the patriarch who bore it, because he was the founder of the second race that sprang from Adam, and in the persons of Noah and his family were to repeople the world.

ZODIACAL LIGHT, a brightness sometimes observed in the zodiac, resembling that of the galaxy or milky way. It appears at certain seasons, viz. towards the end of winter, and in spring after sun-set, or before his rising in autumn, and beginning of winter, resembling the form of a pyramid, lying lengthways with its axis along the zodiac, its base being placed obliquely with respect to the horizon.

The zodiacal light, according to Mairan, is the solar atmosphere, a rare and subtle fluid, either luminous by itself, or made so by the rays of the sun surrounding its globe, but in a greater quantity, and more extensively, about his equator, than any other part. Mairan says, it may be proved from many observations, that the sun's atmosphere sometimes reaches as far as the earth's orbit, and there meeting with our atmosphere produces the appearance of an aurora borealis.

The length of the zodiacal light varies sometimes in reality, and sometimes in appearance only, from various causes.

Cassini often mentions the great resemblance between the zodiacal light and the tails of comets. The same observation has been made by Fatio; and Euler endeavoured to prove that they were owing to similar causes. See "*Decouverte de la Lumiere Celeste que paroît dans le Zodiaque*," art. 41. Lettre a M. Cassini, printed at Amsterdam in 1686. Euler, in *Mem. de l'Acad. de Berlin*, tom 2. This light seems to have no other motion than that of the sun itself; and its extent from the sun to its point is seldom less than 50 or 60 degrees in length, and more than 20 degrees in breadth; but it has been known to extend to 100 or 103° , and from 8° to 9° broad.

It is now generally acknowledged, that the electric fluid is the cause of the aurora borealis, ascribed by Mairan to the solar atmosphere, which produces the zodiacal light, and which is thrown off chiefly, and to the greatest distance, from the equatorial parts of the sun, by means of the rotation on his axis, and extending visibly as far as the orbit of the earth, where it falls into the upper regions of our atmosphere, and is collected chiefly towards the polar parts of the earth in consequence of the diurnal revolution, where it forms the aurora borealis. And hence it has been suggested as a probable conjecture, that the sun may be the fountain of the electrical fluid, and that the zodiacal light, and the tails of comets, as well as the aurora borealis, the lightning, and artificial electricity, are its various and not very dissimilar modifications. See Biot's *Astronomie Physique*, art. 254; and Gregory's *Translation of Haüy's Philosophy*, vol. ii. art. 628.

ZONE, in Geography and Astronomy, a division of the earth's surface, by means of parallel circles, chiefly with respect to the degree of heat in the different parts of that surface. The ancient astronomers used the term zone to explain the different appearances of the sun and other heavenly bodies, with the

length of the days and nights; and the geographers, as they used the climates, to mark the situation of places; using the term climate, when they were able to be more exact, and the term zone when less so. The zones were commonly accounted five in number; one a broad belt round the middle of the earth, having the equator in the very middle of it, and bounded towards the north and south by parallel circles passing through the tropic of Cancer and Capricorn. This they called the torrid zone, which they supposed not habitable on account of its extreme heat. Though sometimes they divided this into two equal torrid zones by the equator, one to the north, and the other to the south; and then the whole number of zones was accounted six. Next from the tropic of Cancer and Capricorn, to the two polar circles, were two other spaces, called temperate zones, as being moderately warm; and these they supposed to be the only habitable parts of the earth. Lastly, the two spaces beyond the temperate zones, about either pole, bounded within the polar circles, and having the poles in the middle of them, are the two frigid or frozen zones, and which they supposed not habitable on account of the extreme cold there. Hence, the breadth of the torrid zone is equal to twice the greatest declination of the sun, or obliquity of the ecliptic, equal to $46^{\circ} 56'$, or twice $23^{\circ} 28'$. Each frigid zone is also of the same breadth, the distance from the pole to the polar circle being equal to the same obliquity, $23^{\circ} 28'$. And the breadth of each temperate zone is equal to $43^{\circ} 4'$, the complement of twice the same obliquity. The difference of zones is attended with a great diversity of phenomena. 1. In the torrid zone, the sun passes through the zenith of every place in it twice a year; making as it were two summers in the year; and the inhabitants of this zone are called Amphiscians, because they have their noon-day shadows projected different ways in different times of the year, northward at one season, and southward at the other. 2. In the temperate and frigid zones the sun rises and sets every natural day of 24 hours. Yet every where, but under the equator, the artificial days are of unequal lengths, and the inequality is the greater as the place is farther from the equator. The inhabitants of the temperate zones are called Heteroscians, because their noon-day shadow is cast the same way all the year round, viz. those in the north zone towards the north pole, and those in the south zone towards the south pole. 3. Within the frigid zones the inhabitants have their artificial days and nights extended out to a great length; the sun sometimes skirting round a little above the horizon for many days together; and at another season never rising above the horizon at all, but making continual night for a considerable space of time. The inhabitants of these zones are called Periscians, because sometimes they have their shadows going quite round them in the space of 24 hours.

ZOOLOGY, is that part of natural history which relates to animals. Linnæus divides the whole animal kingdom into six classes, viz. *Mammalia*, includes all animals that suckle their young. *Aves*, or birds. *Amphibia*, or amphibious animals. *Pisces*, or fishes. *Insecta*, or insects. *Vermes*, or worms. The first class, *Mammalia*, is subdivided into seven orders. See MAMMALIA.—The second class *Aves*, is subdivided into six orders. See AVES.—The third class, *Amphibia*, is divided into two orders. See AMPHIBIA.—The fourth class, *Pisces*, is subdivided into six orders. See PISCES.—The fifth class, *Insecta*, is subdivided into seven orders. See INSECT.—The sixth class, *Vermes*, is divided into five orders. See VERMES.—For more particular information concerning the several branches and subjects of zoology, the reader may consult the various articles above referred to, and he will find most of the genera described in their order in the alphabet.

ZOONATES. Combinations of the zoonic acid with the salifiable basis.

ZOONIC, is the liquid procured by distillation from animal substances, which had been supposed to contain only carbonate of ammonia and an oil.

ZOOPHYTA, in Natural History, an order of the class *vermes*. Zoophyta are composite animals holding a medium between animals and vegetables. Most of them take root and grow up into stems, multiplying life in their branches and deciduous buds, and in the transformation of their animated blossoms or polypes, which are endowed with spontaneous motion. Plants therefore resemble zoophyta, but are destitute of animation and the power of locomotion; and zoophyta are, as it were, plants, but furnished with sensation and the organs of spontaneous motion. Of these some are soft and naked, and others are covered with a hard shell: the former are by some naturalists called zoophytes, and the latter are denominated lithophytes. The coral reefs that surround many islands, particularly those in the Indian Archipelago, and round New Holland, are formed by various tribes of these animals, particularly by the *Cellepora*, *Isis*, *Madrepora*, *Millepora*, and *Tubipora*. The animals form these corals with such rapidity, that enormous masses of them very speedily appear where there were scarcely any marks of such reefs before.

ZOPISSA, *Naval Pitch*, a mixture of pitch and tar scraped from the bottoms of ships that have been long at sea. This composition, by having been gradually penetrated by the salt of the sea, becomes impregnated with its qualities; and being applied to the body externally, is found resolute and desiccative.

ZUMIC ACID, a name given to a peculiar acid principle lately obtained from rice.

**WORKS PUBLISHED BY H. FISHER, SON, AND P. JACKSON, 38, NEWGATE-STREET,
AND SOLD BY ALL BOOKSELLERS.**

I.

THE PANORAMA OF SCIENCE AND ART; embracing the Sciences of Aërostation, Agriculture and Gardening, Architecture, Astronomy, Chemistry, Electricity, Galvanism, Hydrostatics and Hydraulics, Magnetism, Mechanics, Optics, and Pneumatics;—the Arts of Building, Brewing, Bleaching, Clockwork, Distillation, Dyeing, Drawing, Engraving, Gilding and Silvering, Loom-making, Japanning, Lacquering, Millwork, Moulding and Casting in Plaster, Painting, Staining Glass and Wood, and Varnishing;—the Methods of Working in Wood and Metal;—and a Miscellaneous Selection of interesting and useful Processes and Experiments. By JAMES SMITH. *Eleventh Edit.* with 49 Engravings. In Two Volumes, 8vo. price £1. 15s. May also be had in 15 Parts, price 2s. 6d. each.

II.

THE MECHANIC; or, Compendium of Practical Inventions: containing more than two hundred articles, selected and original, arranged under the following heads:—1. Manufactures and Trade; 2. Philosophical Apparatus and the Fine Arts; 3. Rural and Domestic Economy, and Miscellanies. Illustrated by upwards of one hundred copperplate Engravings, quarto and octavo; with a copious Index. By JAMES SMITH, author of the "Panorama of Arts." In two vols. 8vo. price £1. 15s.; may also be had in Parts, price 2s. each. *Sixth Edition.*

III.

THE CARPENTER AND JOINER'S COMPANION, in the Geometrical Construction of Working Drawings, required in the progress of BUILDING; comprehending also a complete SYSTEM OF LINES. Embellished by upwards of 120 Descriptive Plates, (many of which are entirely new Inventions,) engraved by eminent Artists, besides numerous DIAGRAMS. This Book derives superior Advantages, from containing every thing that the MASTER and WORKMAN may need, both in Practice and Theory, whilst its size will render it portable, and thus a CONVENIENT COMPANION. By MICHAEL ANGELO NICHOLSON. Improved from the original Principles of Mr. PETER NICHOLSON.

"This Volume includes New Treatises on Geometry, Trigonometry, Conic Sections, Perspective, Shadows, and Elevations; with the Theory and Practice of the Five Orders of Architecture. In fact, the subjects will be found more numerous, more fully explained, and the Engravings more accurate, than in any other Work on Carpentry and Joinery hitherto Published."—PETER NICHOLSON.—In one vol. octavo, price 23s.

IV.

THE PRACTICAL CABINET-MAKER, UPHOLSTERER, AND COMPLETE DECORATOR. By PETER and MICHAEL ANGELO NICHOLSON.—"To His Majesty George the Fourth, the Patron of the Fine Arts, this Elegant, Unique, and Superb Work, is respectfully dedicated by His Majesty's humble and obedient Servants, P. and M. A. NICHOLSON."—Illustrated by upwards of 100 coloured and plain Engravings. Publishing in Parts, at 5s. each. Quarto.

Also, as an Appendix to the above, **DESIGNS OF FRENCH AND OTHER FOREIGN CABINET AND UPHOLSTERY, FURNITURE, DECORATIONS, &c.** Coloured, in 1s. Numbers, and Parts 5s. each.

V.

The Second Edition of A NEW GEOGRAPHICAL DICTIONARY; containing a Description of all the Empires, Kingdoms, States, and Provinces, with their Cities, Towns, Mountains, Capes, Ports, Rivers, Lakes, &c. in the KNOWN WORLD. A correct Account of the Government, Customs, Manners, and Religion of the Inhabitants;—the Extent, Boundaries, and natural Productions, of each Country;—their Trade, Manufactures, and Commerce;—the Longitude and Latitude of all the Cities and Towns, with their Bearings and Distances from remarkable Places;—and the various Events by which they have been distinguished. Together with the POPULATION of the Counties, Cities, and Towns, in ENGLAND, SCOTLAND, and WALES. With an Appendix of the most remarkable Places mentioned in ancient Geography, with their modern Names. The whole compiled from the best modern Authorities. By J. W. CLARKE, Esq. of the Record Office, Exchequer.—In two volumes, quarto, price £5.; or in 20 Parts, at 5s. each; printed on fine paper, enriched with sixty-three interesting Views; and a complete Atlas, coloured.

VI.

THE UNIVERSAL HERBAL; or, Botanical, Medical, and Agricultural Dictionary. Containing an account of all the known Plants in the World, arranged according to the Linnean System. Specifying the Uses to which they are, or may be applied,—whether as Food, as Medicine, or in the Arts and Manufactures; with the best Methods of Propagation, and the most recent Agricultural Improvements. Collected from indisputable Authorities. Adapted to the Use of the Farmer, the Gardener, the Husbandman, the Botanist, the Farmer, and Country Housekeepers in general. By THOMAS GREEN. *Second Edition*, revised, and much improved, with many important Additions.—In two volumes, quarto, with 109 Plates, coloured, price £7.: plain, £3. 10s. May also be had in Parts, with coloured plates, 10s. each; plain 5s.

VII.

A New and Correct Edition of SHAKSPEARE'S ENTIRE DRAMATIC WORKS: in One Volume, newly arranged, Edited, and Revised, by C. H. WHEELER. Published from the last Standard Edition of Stevens, with Glossarial Notes, Literary and Historical Notices, Rowe's Critique on the Life, Genius, and Writings of Shakspeare, &c.—A slight comparison of the present unrivalled Edition of Shakspeare's Dramatic Works, with those which have recently been issued, will sufficiently establish its superior claim to the attention of the Public. Price, 16s. bds. or in Parts at 3s.

VIII.

A CRITICAL PRONOUNCING DICTIONARY, and EXPOSITOR of the ENGLISH LANGUAGE: to which are prefixed, the Principles of English Pronunciation: interspersed with Observations, Etymological, Critical, and Grammatical. By JOHN WALKER, author of Elements of Elocution, Rhyming Dictionary, &c. &c.

This new and beautiful EDITION of WALKER has been thoroughly examined, and several Additions of Words and Phrases made. It is printed from a Type cast expressly for it, by Caslon and Livermore; and enriched by a Portrait of WALKER, engraved on Steel. Price 9s. boards.

Lunar Civil YEAR, is either the common or embolismic.

The **Common Lunar YEAR**, consists of 12 lunar civil months; and therefore contains 354 days. And

The **Embolismic, or Intercalary Lunar YEAR**, consists of 13 lunar civil months, and therefore contains 384 days.

Thus far we have considered years and months with regard to astronomical principles, upon which the division is founded. By this, the various forms of civil years that have formerly obtained, or that do still obtain, in divers nations, are to be examined.

Civil YEAR, is that form of the year which every nation has contrived or adopted for computing their time by. Or the civil is the tropical year, considered as only consisting of a certain number of whole days: the odd hours and minutes being set aside, to render the computation of time, in the common occasions of life, more easy. As the tropical year is 365 days, 5 hours, 49 minutes, or almost 365 days, 6 hours, which is 365 days and a quarter; therefore, if the civil year be made 365 days, every fourth year it must be 366 days, to keep nearly to the course of the sun. And hence the civil year is either common or bissextile.

Common Civil YEAR, is that consisting of 365 days; having seven months of 31 days each, four of 30 days, and one of 28 days; as indicated by the following well-known memorial verse:—

Thirty days hath September,
April, June, and November;
February twenty-eight alone,
And all the rest have thirty-one.

Bissextile, or Leap YEAR, contains 366 days, having one day extraordinary, called the intercalary, or bissextile day, and takes place every fourth year. This additional day to every fourth year was first introduced by Julius Cæsar, who, to make the civil years keep pace with the tropical ones, contrived that the six hours which the latter exceeded the former should make one day in four years, and be added between the 24th and 23d of February, which was their 6th of the calends of March; and as they then counted this day twice over, or had *bis sexto calendas*, hence the year itself came to be called *bis sextus*, and *bissextile*. However, among us, the intercalary day is not introduced by counting the 23d of February twice over, but by adding a day at the end of that month, which therefore in that year contains 29 days. A farther reformation was made in the civil year by pope Gregory.

The civil or legal year, in England, formerly commenced on the day of the Annunciation, or 25th of March; though the historical year began on the day of the circumcision, or 1st of January; on which day the German and Italian year also begins. The part of the year between these two terms was usually expressed both ways; as 1745-6, or 1744. But by the act for altering the style, the civil year now commences with the 1st of January.

Ancient Roman YEAR. This was the lunar year, which, as first settled by Romulus, contained only ten months, of unequal numbers of days, in the following order, viz.:—March 31; April 30; May 31; June 30; Quintilis 31; Sextilis 30; September 30; October 31; November 30; December 30; in all 304 days; which came short of the true lunar year by 50 days, and of the solar by 61 days. Hence, the beginning of Romulus's year was vague, and unfixed to any precise season; to remove which inconvenience, that prince ordered so many days to be added yearly as would make the state of the heavens correspond to the first month, without calling them by the name of any month. Numa Pompilius corrected this irregular constitution of the year, composing two new months, January and February, of the days that were to be added to the former year. Thus Numa's year consisted of 12 months, of different days, as follow, viz.:—

January 29;	- -	February 28;	- -	March 31;
April 29;	- -	May 31;	- -	June 29;
Quintilis 31;	- -	Sextilis 29;	- -	September 29;
October 31;	- -	November 29;	- -	December 29;

in all 355 days; therefore exceeding the quantity of a lunar civil year by one day; that of a lunar astronomical year by 15 hours, 11 minutes, 22 seconds; but falling short of the com-

mon solar year by 10 days, so that its beginning was still vague and unfixed. Numa, however, desiring to have it begin at the winter solstice, ordered 22 days to be intercalated in February every second year, 23 every fourth, 22 every sixth, and 23 every eighth year. But this rule failing to keep matters even, recourse was had to a new way of intercalating; and instead of 23 days every eighth year, only 15 were to be added. The care of the whole was committed to the pontifex maximus; who, however, neglecting the trust, let things run to great confusion. And thus the Roman year stood till Julius Cæsar reformed it.

The **Ancient Egyptian YEAR**, called also the year of Nabonassar on account of the epocha of Nabonassar, is the solar year of 365 days, divided into 12 months of 30 days each, besides five intercalary days added at the end. The names, &c. of the months are as follows:—1. Troth. 2. Paophi. 3. Athyr. 4. Chojac. 5. Tybi. 6. Mecheir. 7. Phamenoth. 8. Pharmuthi. 9. Pachon. 10. Pauni. 11. Epiphis. 12. Messori; beside the ἡ μέραι επαγομεναι.

The **Ancient Greek YEAR**, was lunar; consisting of 12 months, which at first had 30 days apiece, then alternately 30 and 29 days, compared from the first appearance of the new moon; with the addition of an embolismic month of 30 days every 3d, 5th, 8th, 11th, 14th, 16th, and 19th year of a cycle of 19 years: in order to keep the new and full moons to the same terms or seasons of the year. Their year commenced with that new moon, the full moon of which comes next after the summer solstice. The order, &c. of their months was thus:—

1. Ἑκατομβαιων, containing 29 days. 2. Μηναγετωνων. 30. 3. Βοηδρομιων, 29. 4. Μαιμακτηριων, 30. 5. Πυανεσιων 29. 6. Ποσειδεων, 30. 7. Γαμηλιων, 29. 8. Αιθιρησιων, 30. 9. Ελαφηβολιων, 30. 10. Μουνυχιων, 30. 11. Θαρρηλιων, 29. 12. Σκιροφοριων, 30.

The **Ancient Jewish YEAR**, is a lunar year, consisting commonly of 11 months, which alternately contain 30 and 29 days. It was made to agree with the solar year, either by the adding of 11, and sometimes 12 days, at the end of the year, or by an embolismic month. The names and quantities of the months stand thus:—1. Nisan, or Abib, 30 days. 2. Jiar, or Zius, 29. 3. Siban, or Siwan, 30. 4. Thammuz, or Tammuz, 29. 5. Ab, 30. 6. Elul, 29. 7. Tisri, or Ethanin, 30. 8. Marchesvan, or Bull, 29. 9. Cisleu, 30. 10. Tebeth, 29. 11. Sabat, or Schebeth, 30. 12. Adar, in the embolismic year, 30. Adar, in the common year, was but 29. Note, in the defective year, Cisleu was only 29 days; and in the redundant year, Marchesvan was 30.

The **Persian YEAR**, is a solar year of about 365 days, consisting of 12 months of 30 days each, with five intercalary days added at the end.

The **Arabic, Mahometan, and Turkish YEAR**, called also the year of the Hegira, is a lunar year, equal to 354 days, 8 hours, and 48 minutes, and consists of 12 months, which contain alternately 30 and 29 days.

The **Hindoo YEAR** differs from all these, and is indeed different in different provinces of India. The best account that we have of it is by Mr. Cavendish, in the Philosophical Transactions of the Royal Society for the year 1792.

YEAR and Day, is a time that determines a right in many cases; and in some works an usurpation, and in others a prescription; as in case of an estray, if the owner, proclamation being made, challenges it not within the time, it is forfeited. So is the year and day given in case of appeal; in case of descent after entry or claim, if no claim upon a fine or writ of right at the common law; so of a villain remaining in ancient demesne; of a man sore bruised or wounded; of protections; of essoins in respect of the king's service; of a wreck; and divers other cases.

YEARDAY AND WASTE, is a part of the king's prerogative, whereby he challenges the profits of their lands and tenements for a year and a day, that are attained of petty treason or felony, whoever is lord of the manor where the lands or tenements belong; and not only so, but in the end may waste the tenements, destroy the houses, root up the woods, gardens, and pasture, and plough up the meadows, except the lord of the fee agrees with him for redemption of such waste, afterward restoring it to the lord of the fee.
